— The books of the Deptford Small-Pox Hospital, which institution takes patients from the whole of the parishes of the metropolis, contain remarkable evidence of the efficiency of vaccination in preventing small-pox from resulting fatally. During the six months ended June 30th last 546 cases were admitted to the hospital. The vaccinated patients numbered 326, the unvaccinated 264, and those in which it was not known whether the patients had been vaccinated or not 46. The deaths among the vaccinated cases numbered only six, or a percentage of 2.5, whilst of the unvaccinated patients 127 died, making an average mortality of 48 in the 100. Of the 46 doubtful cases nine died. — *British Medical Journal*.

— In view of the possible danger arising from the soluble salts of tin in goods put up in tin cans, the Director General of Customs of France has issued an important decree forbidding the soldering of tin cans on the inside, and the use of tin plate except that made of pure tin in their manufacture.

PHARMACEUTICAL NOTES.

TINCT. FERRI CHLORIDI.

Dr. E. R. Squibbs says that the present revision of the United States Pharmacopœia makes a great mistake in permitting the acid solution of ferric chloride to be used in making up the tincture as it is wanted for use. It is not fit until at least six months old, and he now never sends it out until it is a year old. An important part of its therapeutic value depends upon ethers that are generated slowly from the alcohol by the large excess of hydrochloric acid present. By the use of his neutral ferric chloride solution much good alcohol has been wasted in the vain attempt of trying to make the tincture. — *Boston Journal of Chemistry*, September, 1881.

ADMINISTRATION OF QUINIA.

Dr. J. C. Stockard recommends quinia to be taken in albumen foam obtained from a well-beaten-up white of an egg. — *Bull. gén. de Thérap.*, June, 1881.

TANNATES OF CINCHONA ALKALOID.

These, obtained by their precipitation by tannin from solutions of the cinchona salts, are being used for administration to children, being tasteless. — *Pharm. Centralhalle*, 1881.

CROTON OIL, NEW METHOD OF APPLICATION.

A mixture of one hundred parts of croton oil with fifty parts each of wax and of cacao butter can be made up into sticks like cosmetic by the aid of a mould,

so as to be applied with great accuracy, both as to extent and depth of action, in such affections of the skin as ringworm, etc. — *British Med. Jour.*, 1881.

B. F. D.

Miscellany.

A CASE OF PISTOL-SHOT WOUND IN THE ABDOMEN.

BY C. E. BRIGGS, M. D.

THE following case, read before the St. Louis Medical-Chirurgical Society, and published in the *St. Louis Courier of Medicine*, is of interest in view of the recent discussions of wounds of this class:—

F. G., a young woman of abandoned life, about twenty years old, was seized with malarial fever in the last week of May, 1881. During the few days of treatment for this disorder she ate but little, and for medicine took quinine, a blue mass purgative, morphia, chloral, and bromide of potassium.

On Monday, the 30th of May, she ate sparingly at noon, and drank some coffee. At about three p. m., in a fit of weariness of life, she determined to commit suicide. Taking a small pistol that carries a conical ball that will nearly pass through No. 17 French catheter scale (that is to say, of about the size of a buck-shot), she tested the pistol by discharging it against the wall, possibly a distance of twelve feet. The ball penetrated not very deeply, I am told. The next shot she put into the upper part of her abdomen, near the median line. Shortly after receiving this wound she vomited blood.

For the next three days she was attended assiduously by several medical men. I saw her for the first time in the evening of Friday, the 2d of June, the beginning of the fourth day. She was then just moved about a mile and a half from the scene of the injury, and had been undergoing much excitement. She was not in much pain; her pulse was 112; her tongue moist.

She was a small, spare woman, and the wound was three fourths of an inch rectangularly to the right of the median line. On a line drawn through it and the navel, the puncture was about one inch from the cartilages of the ribs and two and a half inches from the navel, while the patient was lying flat on her back. There was no wound in the back, and during her illness no localized pain or swelling in the back indicated the presence of the ball, which was also fruitlessly looked for in the passages from the bowels. The probable course of the ball was to be conjectured from the site of the wound, the facts that the pistol had been in the hand of the patient, and that the ball had not had sufficient force to pass through the body, and also from the vomiting of blood soon after the shooting. While there was tenderness about the wound the abdomen did not present the signs of any considerable peritonitis. Attempts made to use the stomach for food or medication previous to my seeing her had been followed by vomiting. She informed me that she had been treated with large hypodermic injections of morphia. The irritability of the stomach was confirmatory of the theory that it had been perforated. The absence of marked peritonitis rendered it probable that there had been little or no leaking from whatever organs had been penetrated. The smallness of the ex-

ternal wound and its closed condition suggested hopeful views of the condition of the track of the ball internally. The test of vomiting which the stomach had undergone without resulting peritonitis seemed to show that while it was probable that this organ had been wounded, the wound, even under a strain, was not permeable. I administered a sixth of a grain of morphia hypodermically. The next morning her pulse had fallen to 100, and her respiration was easy and regular, but the night was reported as restless, with bilious and watery vomiting. An attempt was made to relieve the irritability of the stomach by medication, and to lessen the acidity of its contents by small quantities of liquid food and iced diluents, which would also come up with less straining than the scanty bilious vomit. At 4.30 p. m., however, it was found that the vomiting had increased, although the pain had not. Pulse 112 again. The general plan of treatment was adopted of feeding by rectum, and the administration of morphia by hypodermics for rest and relief from pain.

On June 4th, at 7.30 A. M. her pulse was 90. Since last visit she had had bilious vomiting six or seven times, and at seven A. M. a small offensive movement from the bowels; at eleven A. M. another, more natural. At 6.30 p. m. her pulse was 104.

June 5th. Had had a restless night, but the vomiting had ceased. She was in no pain, but complained of being ravenously hungry. Her pulse was 104 at first, but at a second examination had fallen to 94. Her menses made their appearance to-day and continued to the 7th inst. At night her pulse had risen to 114; her tongue was nearly clean.

June 6th. Pulse 112. During the night she had imposed upon an attendant, and obtained from her a half pint of tea and drunk it. She has not vomited, and has no pain. At one p. m. she had a dark watery movement amounting to about a pint. At 2.30 p. m. she vomited somewhat more than a pint of bilious water, and at 4.15 half a pint more. Her pulse at about six p. m. was 104, with a quick stroke; her tongue dark red, and there was pain near the external wound. This day completed the first week of the case, which terminated fatally on the first day of the seventh week.

The patient suffered throughout comparatively little direct pain from the wound, but doubtless had a great deal of nervous discomfort. Her violence, when refused, rendered it impracticable to lessen as much as I desired the amount of morphia given hypodermically. She had not been previously an opium eater, but had used freely alcoholic stimulants; and her disordered life and habits of self-indulgence had produced an infirmity of will which made her unmanageable as a patient, notwithstanding her desire for life. She had no attack of delirium tremens, and the diurnal periodicity seemed to have no connection with a malarial taint. There was an attack of prostration in the second week, and the abdomen became tender but not tympanitic. The pulse rose to 120 in the beginning of the third week, and there were obscure signs of an abscess, rather superficial, presenting a hardness between the wound and the right inguinal region two inches by three in dimensions. These local symptoms disappeared in the fourth week, and blood began to appear in the vomit. An attempt was made to substitute laudanum by the rectum for the hypodermics of morphia, which, as is well known, often cause nausea and vomiting; but the re-

sult was not satisfactory. In the middle of the fifth week the vomiting became excessive. In the middle of the sixth, she was vomiting twenty and thirty times in twenty-four hours. The pulse went up to 140, and, after a struggle for three days, she succumbed on the 12th of July.

Post-mortem. The examination was made eight hours after death.

Externally the body showed decided emaciation and marked rigor mortis. The thickly-strewn petechiae had become bloodless and almost imperceptible. The abdomen was flat and hard. On section the peritoneum was slightly congested directly under the wound, and a few thread-like adhesions connected it with the parts below. There was no perceptible scar on the inner surface of the abdominal parietes where the ball had passed through. The gall-bladder was full. Over the right border of it, about three fourths of an inch from the edge of the liver, was the scar of a perforation, the course of which through the liver was perhaps half an inch. The wall of the gall-bladder was congested and adherent to the under side of the liver. The stomach contained about four ounces of fluid. It presented no scar or sign of wound. The cardiac extremity was decidedly congested. The first two inches of the duodenum were inflated, and about one inch below the pylorus were two scars, as if of the entrance and exit of the ball. Beyond this we could not trace the course of the ball, being able to find no scar on the posterior peritoneum, nor any little hardness in the emaciated tissues behind the duodenum. Nor were there any signs in life of injury to the spinal cord, nor pain in the vertebral column. There was marked congestion of the peritoneum enveloping the organs below the right of the liver. The small intestines, as presenting on opening the body, were healthily inflated, and not adherent to each other or to adjacent tissue, as if the peritonitis had been chiefly confined to the lesser cavity of the peritoneum.

The heart was contracted and normal. No deposit of pus was anywhere found, and there was no effusion in the abdominal cavity.

Remarks. It seemed that the ball had passed through the anterior parietes of the abdomen, then through the edge of the liver, slightly wounding the sac of the gall-bladder, then through the duodenum (this part of which is not bound down), and then glancing upon the posterior parietes of the abdomen, its force being expended, it had gradually found its way, perhaps, into the pelvis. The blood vomited shortly after the wound was inflicted must have come from the wound in the duodenum. It does not seem impossible that some of it may have come from the gall-bladder. I attribute part, at least, of the irritability of the stomach to her previous intemperate habits. The vomiting of blood in the fifth week, I surmise, came from the rupture of some small blood-vessels in the congested stomach from the violence and frequency of the vomiting.

PROFESSOR ANNANDALE ON HOMOEOPATHY, ETC.

A CONSIDERABLE portion of the address in medicine before the British Medical Association by Dr. Bristowe was devoted to a consideration of Hahnemann and homoeopathy. This address was published in full in the JOURNAL from advance sheets. Another prom-

inent British physician, Professor Annandale, of Edinburgh, having lately touched upon the same topic, we extract from the *Lancet* a brief report of his remarks with its comments:—

"At the recent medical graduation in Edinburgh, Professor Annandale delivered the valedictory address to the one hundred and seventy-three new graduates, not ten of whom he expected to remain north of the Tweed. He chose for his address the subject of Quackery, which, he said, was to be found in other professions beside that of medicine. He took a large and liberal view of the question, and expressed the perfect right of the public to please itself, and of patients to please themselves, by changing their medical adviser, or by having a bone-setter, rubber, or mesmerist. On the subject of homoeopathy, not being in the Council of the British Medical Association, he seems still to be somewhat old-fashioned, though slightly at a loss to know what homoeopathy now means. We must make room for what appears to us sound sense and good ethics on this question in its present stage. The Professor said:—

"My difficulty in regard to homoeopathy is that, judging from the recent correspondence and discussions on the subject, the majority of homoeopathic practitioners no longer acknowledge or practice in their entirety the principles of the original founder of the system. I understand that they now make use of homoeopathy, allopathy, or any other treatment which they consider likely to be useful—I might in some, I hope not in many, instances, say agreeable—to their patients. Why, then, call themselves homoeopaths? and why do they let it be understood that their treatment is a special one, or is in any way superior to that practiced by the ordinary practitioner? The position of homoeopathic practitioners is a present both illogical and inconsistent as regards the practice of medicine; and I say that they should either hold to the original principle of homoeopathy and call themselves true homoeopathic practitioners, or they should retire from the ranks of homoeopathy, return to the field of the ordinary profession, and give up their pretensions to cure all diseases by any special system which is peculiar to themselves. . . . Perhaps the best advice I can give you in regard to the treatment of homoeopathy is to treat it as most sensible people treat aesthetics. I have no desire to say anything that is discourteous or personal in regard to homoeopathic practitioners themselves. Many of them are educated gentlemen, and are qualified members of our profession; but it is impossible, under present circumstances, that you can have any true sympathy with them in the matter of medical practice. You cannot meet them in consultation, because, although you might agree with them as to the nature or diagnosis of a case of disease, one or other of you must consent to sacrifice your principles and belief when the treatment of the disease has to be decided, and no man with any proper feeling will do this, or should do it, more particularly when the health or life of a human being is concerned."

"Mr. Annandale wound up with a few pieces of advice to the young graduates, which we heartily endorse. First, not to think that they were fully equipped with all knowledge, but to go on learning the practical parts of their profession. Secondly, not to consider that they had any vested interest in their patients. Thirdly, while willing in proper circumstances of poverty, misfortune, etc., to give their services, they must, as a rule,

expect and require from their patients*proper monetary remuneration. Fourthly, never to object to consultations with their professional brethren if their patients desire it. Fifthly, not to enter too actively into the region of politics, general, local, or theological."

GERMAN PHARMACISTS.

THE young man who wishes to be accepted as an apprentice ("Lehrling," in German) in pharmacy has first to prove that he has passed the examinations which are demanded for an "einjähriger Freiwilliger" in the army; but it is necessary that these examinations shall have been passed in a college where Latin is an obligatory branch of study. This corresponds with the English "First or Preliminary Examination," but must be regarded as much more severe; for it is necessary that the young man shall have been one year in the "Secunda," that is, the highest class but one in the German classical school, and this German examination is nearly equivalent to the Oxford and Cambridge Middle Class Examinations.

When these claims are fulfilled, the candidate must stay three years in a pharmacy; if he has passed "das Abiturienten-Examen" (that is, the final examination for the highest class in the classical school) he needs to remain only two years as an apprentice in the pharmacy. It must be mentioned here that there is a strong party among the German pharmacists who wish that the German Government shall demand this "Abiturienten-Examen" as the basis for all pharmaceutical education.

When the candidate has finished his apprenticeship, he passes his first pharmaceutical examination, the "Gehülfeprüfung" (that is, examination for assistants), required after January 1, 1876, by the law of November 13, 1875. This examination is not passed in the universities, but before special boards of examiners which are found throughout all Germany, and which consist of two pharmacists and a physician. The "Gehülfeprüfung" is in three divisions and lasts two days.

(1.) *The written examination* consists of three questions in chemistry, in botany or materia medica, and in physics. The candidates are watched during the six hours which are accorded for the answering of these three questions, and no access to books is allowed.

(2.) *The practical examination* consists in: (a) reading, preparing, and taxing three prescriptions; (b) preparing one "galenical" and one chemico-pharmaceutical preparation after the Pharmacopœia Germanica; (c) examining the purity of two of the chemical preparations of the Pharmacopœia Germanica. With these practical tests the candidate must present his "Laborations-journal," which he has prepared during the three years of apprenticeship and which includes a short description of all the work he has done in the laboratory in the three years.

(3.) *The oral examination* consists in: (a) recognizing and determining several fresh or dried plants; (b) explaining the derivation, adulteration, and pharmaceutical use of several drugs and chemical preparations and explaining their composition and preparation; (c) translating two articles of the Pharmacopœia Germanica; (d) knowing the elements of botany, pharmaceutical chemistry, and physics. With this oral test the candidate must present his *herbarium vivum*, that is,

an herbarium which is collected and arranged by himself during his apprenticeship.

This "Gehülfeprüfung" corresponds to the English "Minor Examination;" but the young man has not yet the permission to possess his own pharmacy: he can only be an assistant.

The candidate must now spend at least three years as an assistant ("Gehülfe") in a pharmacy, and after this stage ("Servirzeit") he may commence his studies for "*die pharmaceutische Staatsprüfung*" (also called "*das Apothekerexamen*," that is, the "Major Examination"). He is now obliged to attend the lectures and to do practical work in the laboratories of the university. Having thus been at least one year and a half occupied only with his studies, he has the right to present himself for this examination, which can be passed in either of the twenty universities of Germany or in one of the three polytechnic schools of Brunswick (Collegium Carolinum), Stuttgart, and Carlsruhe. This examination is demanded by the law of March 5, 1875, and consists of the following five parts:—

(1.) *Preliminary (written)*. Three questions in botany or materia medica, in inorganic and organic chemistry.

(2.) *Pharmaceutical, technical*. To make two "galenical" preparations and two chemico-pharmaceutical preparations.

(3.) *Analytical, chemical*. (a.) Qualitative and quantitative (gravimetric and volumetric) analyses; (b.) toxicological research (qualitative and quantitative).

(4.) *Pharmaceutical, scientific (oral)*. In botany, materia medica, and pharmaceutical chemistry.

(5.) *Final* ("Schlussprüfung") is also a scientific oral examination and is held in botany, chemistry, and materia medica by the professors of the university and in the laws of pharmacy by an apothecary.

Only after having passed this last examination has the German pharmacist permission to possess a pharmacy, but even then he cannot, as in France and England, establish himself without a privilege of the Government. — *Pharm. Journ.*

EYESTONES.

THE following account of these popular nuisances is interesting. It might properly be followed by an anathema on all who resort to their use.

"Eyestones are composed of calcareous material, and when placed in a smooth plate containing a weak solution of lime-juice or vinegar are slowly moved about by the evolution of carbonic acid gas. It is from this fact that ignorant people imagine that the eyestone has life, and a particular weakness for vinegar, in which above all other fluids it delights to swim.

"Most of the eyestones sold to the wholesale drug dealers of New York city are supplied to them by sailors employed on vessels engaged in the fruit trade of Venezuela and other South American republics. They are regarded with mystery and awe by the native inhabitants, by whom they are collected in large quantities.

"A very prevalent error exists as to the origin of eyestone. Many persons imagine, and many works on the subject state, that the eyestone is the product of the fresh-water lobster or crayfish, and that the stones are found in the stomach of the above-named animal, and constitute a storage of lime during the moulting

season. This is not so. The stones found in the crayfish are known as crabstones. In Poland, Russia, and Astrachan the crayfish are rotted in deep pits dug in the earth, after which the refuse is washed to obtain the crabstones, which are used in many parts of Europe to correct stomachic difficulties.

"Nearly all univalve shells have an operculum or door that fits closely to the inside of the mouth or opening of the shell. This door is generally situated on the upper side of the back part of the foot on which the animal moves. When the univalve draws in his body the operculum is the last part that is taken into the cavity or mouth of the shell, where it fits so accurately, and is of such a horny or calcareous nature, that it affords perfect protection to the animal against enemies from without. The operculum is an exact representation or duplication of an eyestone on a very large scale. In fact, all eyestones are operculums or small, close-fitting doors that are used by the eyestone bearing univalves to protect them from intruders.

"The under side of the eyestone is composed of numerous slightly concentric grooves. When moving over the eyeball the grooves collect and retain all foreign substances. The movement of the eyestone is caused by the pressure of the eyeball against the stone."
— *Scientific American*.

SEWAGE FARMING.

THE following description of the Croydon Sewage Farm is cut from the editorial columns of the *London Medical Times and Gazette*:—

The total area of the farm is 540 acres, but of these only 450 are regularly irrigated. On these is poured daily the sewage of about 63,000 persons, averaging in dry weather 2,000,000 gallons, but rising, when the rainfall is added, to sometimes twice that volume with no further treatment than a coarse straining to separate sticks, rags, paper, and such solid masses. The sewage is conveyed to every part of the estate by a system of channels and feeders, and turned on to each field in order for twelve to twenty-four hours at a time. The smallest trenches are dammed at intervals by boards, to distribute the flow over the land. After having been thus filtered through one field, it is conducted in like manner to a second or a third before it is allowed to pass into the River Wandle.

The effluent water is clear and devoid of taste and smell, and numbers of young fish may be seen in the conduit by which it leaves the farm. Even in parts actually submerged to the depth of an inch or more no odor is perceptible; none anywhere, in fact, save in the neighborhood of an uncleansed ditch, and there not to be compared with the stench arising from the turning over of an ordinary dunghill.

In short, it may be now taken as proved that sewage in a state of minute subdivision and of intimate contact with fresh earth does not undergo the septic changes to which it is prone in mass. On this depends the sanitary success of the earth-closet; but the sewage farm presents this advantage: that while the growing vegetation, constantly removing organic matter from the land, keeps it from becoming surcharged therewith, it at the same time avoids that prolonged, and therefore complete and destructive, oxidation of the organic matter which detracts so much from the fertilizing power of the earth from the closet.

The principal crop, as on all sewage farms, is Italian rye-grass, a plant whose powers of absorption are enormous. On common pastures it yields two crops in a season; here it is cut seven times, each crop averaging fifty to sixty tons, and worth £5 to £6 per acre. It is mostly used as green fodder, but there is no reason why it should not be made into hay, which would find a ready sale. Mangel-wurzel is also largely grown. These crops are specially suited for sewage culture, but none need be excluded, and good fields of wheat may now be seen on land which has not been irrigated since the corn was sown. The cattle kept on the farm are fattened for the butcher solely on its produce at the rate of four head per acre, ordinary pastures supporting not more than one. This is a most important fact in relation to the problem of our meat supply.

The question of the influence of sewage farms on the health of the surrounding population has also been conclusively settled by the farm under consideration. The population of the adjacent town of Croydon has risen in the past decade from 53,000 to 77,000, and the birth-rate, which always entails a proportionate mortality, is unusually high, yet the death-rate of Croydon has steadily decreased, until for several years it has not exceeded 16 per 1000—that of London being 22. In Beddington it is only 14 in a population of 5000, many of whom unwittingly drink the effluent water, as is shown by the rise in the nearest wells which follows each irrigation. In the very midst of the farm stands the Orphan Asylum, and the visitors had an opportunity of bearing witness to the healthy appearance of the girls—165 in number. About one death has occurred yearly from phthisis or tubercular disease; there has not been a fatal case of any zymotic disease.

All opposition in the neighborhood has been disarmed by experience, and the value of property in Beddington has doubled in the last ten years, the proximity of the sewage farm not having deterred the wealthy citizens of London from erecting their villas around. All claims for compensation made against the projectors of similar schemes have therefore no foundation in fact, and should be strenuously opposed.

OPHTHALMOLOGY: MIDDLEMORE FUND PRIZE ESSAY.

THE interest on the fund of five hundred pounds given in trust to the British Medical Association by Mr. Richard Middlemore, of Birmingham, to found a prize for the best essay on ophthalmology, having accumulated for three years, the committee of council now offer, in accordance with the terms of the trust deed, a prize of fifty pounds for the best essay on the Scientific and Practical Value of Improvements in Ophthalmological Medicine and Surgery made or published during the past three years. The successful essay will be the property of the Association. Essays must be in English or accompanied by an English translation, and forwarded under cover, with a sealed envelope bearing the motto of the essay, and containing the name and address of the author, addressed to the General Secretary of the British Medical Association, 1610 Strand, London, and must be in his hands on or before May 31, 1882. — *British Medical Journal*.

Twenty-three Massachusetts towns.....	182,365	78	34	39.74	26.92	3.85	1.28	3.85

Deaths reported 3560 (no report from New Orleans): 1827 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1350, diarrhoeal diseases 728, consumption 375, diphtheria and croup 180, lung diseases 170, typhoid fever 132, malarial fevers 82, scarlet fever 75, small-pox 56, whooping-cough 36, cerebro-spinal meningitis 30, puerperal fever 12, erysipelas 10, measles eight, typhus fever one. From *malarial fevers*, New York 26, St. Louis 15, District of Columbia 10, Chicago nine, Brooklyn and Baltimore eight, New Haven three, Buffalo two, Nashville one. From *scarlet fever*, New York 26, Brooklyn 18, Philadelphia 15, Pittsburgh six, Chicago, St. Louis, Baltimore, and Buffalo two, Milwaukee and Providence one. From *small-pox*, Philadelphia 25, Chicago 14, Pittsburgh 11, New York four, Brooklyn and Cincinnati one. From *whooping-cough*, New York 11, Brooklyn six, Chicago and Boston five, St. Louis two, Philadelphia, Pittsburgh, Buffalo, Providence, Malden, Beverly, and Nantucket one. From *cerebro-spinal meningitis*, New York nine, Chicago four, Cincinnati and Fall River three, Milwaukee, Worcester, and Chelsea two, St. Louis, Baltimore, Pittsburgh, Holyoke, and Attleborough one. From *puerperal fever*, Chicago and St. Louis three, Boston and Pittsburgh two, Brooklyn and New Haven one. From *erysipelas*, New York four, Chicago two, Philadelphia, Brooklyn, St. Louis, and Baltimore one. From *measles*, New York five, Baltimore two, Providence one. From *typhus fever*, New York one. Thirty-seven deaths occurred in New York from the direct effects of solar heat, and three in Cincinnati.

Eight cases of small-pox were reported in Brooklyn, seven in St. Louis, 42 in Pittsburgh, one in Milwaukee; diphtheria 21, scarlet fever five, in Boston; diphtheria six, scarlet fever two, in Milwaukee. Dysentery is epidemic in Buffalo; 27 fatal cases occurred during the week.

In 40 cities and towns of Massachusetts, with a population of 1,048,703 (population of the State 1,783,086), the total death-rate for the week was 24.81 against 26.74 and 22.85 for the previous two weeks.

For the week ending August 13th in 149 German cities and towns, with estimated populations of 7,841,624, the death-rate was 30.5. Deaths reported 4596; under five 2943; diarrhoeal diseases 517, pulmonary consumption 405, acute diseases of the respiratory organs 211, scarlet fever 105, diphtheria and croup 92, typhoid fever 53, whooping-cough 52, measles and röteln 22, puerperal fever 18, typhus fever (Königsberg, Thorn two, Potsdam) four, small-pox (Königsberg, Berlin, Kottbus) three. The death-rates ranged from 14.1 in Elberfeld to 48.1 in Chemnitz; Königsberg 31; Breslau 43.1; Munich 38.9; Dresden 35.7; Berlin 35.5; Leipzig 32.2; Hamburg 29; Hanover 22.4; Bremen 21.9; Cologne 29.8; Frankfurt 16; Strassburg 40.8.

For the week ending August 20th in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 21.7. Deaths reported 3169; diarrhoea 412, scarlet fever 122, measles 83, whooping-cough 73, fever 45, small-pox (London 38) 39, diphtheria 15. The death-rates ranged from 13.9 in Plymouth to 37.3 in Leicester; Bristol 17.9; Leeds 19.3; Birmingham 20; London 20.1; Sheffield 22.5; Manchester 23.4; Liverpool 27.9. In Edinburgh 16.6; Glasgow 19.8; Dublin 15.5.

In the 21 chief towns of Switzerland, for the week ending August 20th, population 479,934, there were 76 deaths from diarrhoeal diseases; whooping-cough nine, acute diseases of the respiratory organs seven, diphtheria and croup four, typhoid fever three, measles one. The death-rates were: Geneva —; Zurich 25.7; Basle 26.8; Berne 25.8.

For the week ending August 20th in 149 German cities and towns, with an estimated population of 7,794,925, the death-rate was 28.6. Deaths reported 4286; under five 2578; diarrhoeal diseases 504, pulmonary consumption 425, acute diseases of the respiratory organs 176, scarlet fever 96, diphtheria and croup 93, typhoid fever 62, whooping-cough 68, measles and röteln 26, puerperal fever 17, small-pox (Thorn, Benthien, Kottbus two, Duisburg) five. The death-rates ranged from 15.7 in Barmen to 54 in Posen; Königsberg 29.5; Breslau 40.9; Munich 38.2; Dresden 30.9; Berlin 30.8; Leipzig 36.4; Hamburg

24.6; Bremen 21.4; Cologne 21.2; Frankfort 24.9; Strasburg 30.4.

For the week ending August 27th in the 21 chief towns of Switzerland, population 479,934, there were 59 deaths from diarrheal diseases; acute diseases of the respiratory organs 11,

typhoid fever 10, diphtheria and croup five, whooping-cough four, puerperal fever one, small-pox one. The death-rates were Geneva 22; Zurich 25; Basle 21.8; Berne 24.6.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM SEPTEMBER 10, 1881, TO SEPTEMBER 16, 1881.

BROWNS, P. R., captain and assistant surgeon. Granted leave of absence for one month. S. O. 210, A. G. O., September 13, 1881.

SKINNER, J. O., captain and assistant surgeon. To proceed to Fort Verde, A. T., and report to the post commander for duty as post surgeon. S. O. 101, Department of Arizona, September 2, 1881.

BERTON, H. G., captain and assistant surgeon. To accompany Light Battery C, Third Artillery, as medical officer, on its march from Fort Hamilton, N. Y., to Yorktown, Va., via Trenton, N. J., Philadelphia and Columbia, Pa., Baltimore, Md., and Washington, D. C., and remain with it there until further orders. S. O. 163, Department of the East, September 14, 1881.

AMERICAN GYNÆCOLOGICAL SOCIETY. — Programme of the sixth annual meeting, to be held in the hall of the Academy of Medicine, 12 West Thirty-First Street, New York, on September 21, 22, and 23, 1881. The profession is cordially invited to attend the meetings.

September 21st. Morning session at 9.30 o'clock. Roll-call, reception of guests, etc. Papers: 1. Address of Welcome by the President of the New York Academy of Medicine. 2. Acute Diffuse Hyperæsthesia of the Peritoneum, following Minor Gynæcological Operations and Manipulations. By Dr. S. C. Busby, of Washington. 3. Exploratory Puncture of the Abdomen. By Dr. H. J. Garrigue, of New York. Appointment of the Auditing Committee. Adjournment at 4 p. m. Afternoon session at three o'clock. 4. Notes on Cases of Pelvic Abscess. By Dr. G. H. Laman, of Boston. 5. Genital Renovation, particularly by Kolpos Tenotomy and Kolpocæpsetis, in Uterine and Faecal Fistules. By Dr. N. Bozeman, of New York. Adjournment at five p. m.

September 22d. Morning session at 9.30 o'clock. 6. Forceful Elongation of Pelvic Adhesions. By Dr. E. Van de Warker, of Syracuse. 7. Sixth Annual Address, by the President, Dr. W. H. Byford, of Chicago. 8. Esthiomène, or Lupus of the Vulva, with Cases and Colored Illustrations. By Dr. L. E. Taylor, of New York. Adjournment at one p. m. Afternoon session at three o'clock. 9. Bursting Cysts of the Abdomen. By Dr. William Goodell, of Philadelphia. 10. Erysipelas in Childbed without Puerperal Peritonitis. By Dr. H. F. Campbell, of Augusta, Ga. 11. The Practice of Gynecology in Ancient Times. By Dr. E. W. Jenks, of Chicago. Adjournment at five p. m.

September 23d. Business meeting at nine a. m. with closed doors. Report of the Treasurer and Auditing Committee.

Election of officers for 1882. Nominations for honorary and active fellowship by the Council. Balloting on the same. Morning session at 10.30 o'clock. 12. Extensive Adhesion of the Bladder as a Complication of Ovariectomy. By Dr. T. G. Thomas, of New York. 13. A Case of Inverted Uterus caused by a Fibroid Polyp. By Dr. T. A. Reamy, of Cincinnati. 14. Axis Traction of the Obstetric Forceps. By Dr. A. H. Smith, of Philadelphia. Adjournment at one p. m. Afternoon session at three o'clock. 15. Jaundice in Pregnancy. By Dr. J. W. Underhill, of Cincinnati. 16. A Case of Clitoridectomy. By Dr. G. J. Engelmann, of St. Louis. 17. Measurements of the Uterine Cavity in Childbed. Second and Third Series of 108 Cases each. By Dr. A. D. Sinclair, of Boston. Adjournment at five p. m. J. R. CHADWICK, M. D., Secretary.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next regular meeting will be held at the Medical Library Rooms, 19 Boylston Place, on the first Thursday of October, at 10.30 a. m. H. A. Martin, M. D., and H. O. Marey, M. D., will report on matters pertaining to the Medical Congress, both of Gynæcological and of general medical interest. Profession invited.

HENRY M. FIELD, M. D., Secretary.

PRIZE ESSAY. — The committee of selection appointed by the chairman of the section on Practical Medicine, Materia Medica, and Physiology, at the recent meeting of the American Medical Association, have selected, and hereby announce, as the subject for the prize to be awarded in 1883, the following question:—

What are the Special Modes of Action, or Therapeutic Effects upon the Human System, of Water, Quinia, and Salicylic Acid, when used as Anti-Pyretics in the Treatment of Disease? The essays must be founded on original experimental and clinical observations, and must be presented to the chairman of the committee of award on or before the first day of January, 1883.

N. S. DAVIS,
H. D. HOLTON,
W. H. ULRICH, } Committee of Selection.

BOOKS AND PAMPHLETS RECEIVED. — Cyclopædia of the Practice of Medicine. Edited by Dr. H. von Ziemssen, Professor of Clinical Medicine in Munich, Bavaria. Vol. XX. General Index. New York: William Wood & Co. 1881.

General Medical Chemistry for the Use of Practitioners of Medicine. By R. A. Wuthaus, M. D. New York: William Wood & Co. 1881. Wood's Library of Standard Medical Authors.

The Dangers and the Duty of the Hour. By William Goodell, M. D. (Reprint.)

Original Articles.

THE MEDICAL EDUCATION OF WOMEN. THE PRESENT HOSTILE POSITION OF HARVARD UNIVERSITY AND OF THE MASSACHUSETTS MEDICAL SOCIETY. WHAT REMEDIES THEREFOR CAN BE SUGGESTED?¹

BY HENRY I. BOWDITCH, M. D., M. M. M. S.

I DESIRE to discuss these questions dispassionately. I hold certain views which I know are honestly and earnestly opposed by some of my best friends; men eminent in the profession, and equally desirous with myself of upholding the honor and the best interests of that profession. I am sorry to differ from such comrades, but I cannot do or say otherwise without incurring my own self-contempt.

As I shall endeavor to discuss the question without undue heat, I hope that I shall not offend the sensibilities of any one. I claim, too, from yourselves an equally non-sentimental hearing. I ask for the strongest arguments you can bring against any position I may take, because by such ample discussion we shall all the sooner arrive at truth upon the matters in dispute. I regret to feel that our discussions in all the medical societies I attend in Boston are, usually, very deficient in this wrestling of one mind with any other upon any subject that may be presented. Often the most important questions are received with a dead and, as it were, ominous silence, save in the private talk or judgments given after we leave this hall. Some, it is true, prefer that there *should be never any discussion of the special subject* I shall present, and they wish that certainly no action should be taken during this our centennial year. Others, on the contrary, think that discussion should be continued until the right prevail, and that it is especially appropriate to this centennial gathering.

The festival would, according to them, be ennobled and consecrated, as it were, by the performance of an act of simple justice, already too long delayed.

AXIOMS.

Before entering upon the specific question announced permit me to lay down a few axioms, which I hope you will admit as simple truisms, perhaps.

(1.) In this country and at this period of the world every adult, male or female, has a right to such an amount and species of instruction, that is offered to the public, as may seem good to that individual mind.

(2.) Sex, though undoubtedly often influencing an individual in the search for such public instruction or work, has nothing to do with this primal right.

(3.) In every class of the community woman has, of late years, claimed and obtained for herself positions and spheres of action which seventy-five or a hundred years ago would not have been claimed by woman, or, if claimed, would not have been granted by our forefathers.

(4.) She now claims all these positions, at times, even, to the exclusion of men. By work in the halls of the State-house, down through all public offices to the lowest clerkship or shop-worker, she often not only supports herself, but sometimes large families, on labor, that would have been repelled by both sexes, a century

since, as unsuited to woman. She has also entered successfully into the higher realms of literature, science, and of professional life, and has gained honors in all of them. The names of Madame De Staël, George Eliot, George Sand, Mary Somerville, La Chapelle, Boivin, dead, and many others, living, prove this for literature, science, and medicine.² The crowds of young women who, morning and evening, fill our streets at the opening and close of the business day, but which were never seen, even thirty years ago, intimate how women engage now in all branches of trade.

(5.) It is a truth, not to be denied, that there are, at present, not a few intelligent women who, loyally bent upon getting a proper medical education, have crossed the ocean once and at times twice in order to get that instruction, which Harvard College refuses to impart to them, or for which the Massachusetts Medical Society gives them no credit. Daily this number of foreign-educated women is increasing, some of whom are in medical acquirements the peers of any in this assembly.

(6.) As a corollary to this proposition, you must admit that Harvard, by her present position, not only forces women to go to Europe or other distant places, but it also compels many, who, from pecuniary circumstances, cannot visit Europe, to take refuge in other and inferior schools, or, perchance, drives some into the ranks of quackery.

OPPOSITION OF HARVARD AND OF THE MASSACHUSETTS MEDICAL SOCIETY.

These facts being admitted, we next ask, how do Harvard College and the Massachusetts Medical Society meet them? Harvard simply ignores them. She shuts her eyes and virtually says: "As we have done for two centuries so we mean to do for an indefinite space of time." It is, however, a curious psychological fact that while she gives in the higher branches of learning usually taught to male undergraduates similar instruction to women, for female students of medicine she refuses all care. Thus she does, as I think, not only injustice to the claims of women but an actual detriment to this community and this, too, to the lowering of her own fame and probably with a pecuniary loss. By this neglect, the State is being gradually flooded by imperfectly-educated female physicians. I cannot see how any one can deny that this is the present unfortunate position of our time-honored university.

The Massachusetts Medical Society stands upon no higher plane. It does not, like the university, give instruction, but, *by a law of Massachusetts, it is obliged to examine persons educated elsewhere, and to give certificate or licenses* to practise medicine to all applicants, who may be found capable of winning such an honor. But when fully educated women come and ask for such examination, it sternly refuses to give it. It gives no intelligent reason for this action and merely replies: "No, do not come near us." "We won't have you." "Your sex unfits you to be our associates." "You cannot practise medicine." "You unsex yourselves in trying to do so, and we won't even examine into your qualifications." "You disturb our meetings by your persistent demands."

² If any one wishes to see how woman has gradually but steadily, progressed in the path of medicine, let him read the admirable and exhaustive article by Dr. J. R. Chadwick, in the *International Review* for October, 1879, entitled, *The Study and Practice of Medicine by Women*. H. I. B.

¹ A paper read before the Suffolk District Medical Society. Vide Boston Medical and Surgical Journal, August 4, 1881, for report of discussions on this paper.

WOMEN PHYSICIANS INCREASE IN NUMBER, IN SIGHT
OF HARVARD AND THE MASSACHUSETTS MEDICAL
SOCIETY.

Notwithstanding this opposition from these two powerful institutions educated female physicians and surgeons have steadily increased in numbers.¹ How unwise, therefore, for these two institutions to think they can stem the tide, which is daily bringing women into this department of human action, where they feel that they will and can be efficient workers. You cannot stop this flood "any more than you can dam Niagara with a bulrush."

Is this procedure on the part of the University and the Society consistent with the duty these institutions, by their very charters, owe the State? Is it justice to the public or to the applicants? Is it consistent with the highest reason? Nay, is it sustained even by the rules of common sense? I take the negative of all these questions, and in so doing I think I stand upon a firm basis. But some of you may reply, we do not rest our opposition upon your so-called high ground, but we base it upon expediency which, on supreme occasions, overrides all of your arguments.

I grant that this position is, at times, applicable to *great emergencies*. But I cannot insult the intellect or the moral sense of this Society by admitting that the fear of giving instruction to women, in any department of learning, can be brought into this category.

THESE TWO BODIES HOLD A GREAT TRUST FROM
THE STATE.

The only question, now open to the College and to the Society, is whether or not they will give up their honorable prestige as leaders in all the higher medical education for every applicant, or relegate that position to an inferior set of instructors. How degrading to Harvard and to the Society is this bare suggestion!

In truth this matter of medical education is a *great trust*, committed by the State to these two bodies, and upon the proper and conscientious performance of the duties devolving upon them in this trust, or their neglect of the same, depends in a great degree the character of the medical profession of Massachusetts for centuries to come.

Let us examine a little more closely into the acts of the two, and after doing this I will venture to suggest a course, which seems to me would be just and reasonable, and which will, perhaps, be not disagreeable even to the minds of opponents to any action in the premises.

A FEW HISTORICAL FACTS. HARVARD COLLEGE.

I regret that the corporation of the College refused to accept the sum of ten thousand dollars, generously offered by a lady provided the College would instruct women in medicine.²

Four out of five of a committee, consisting of the

¹ There are at least twenty-five women, well educated as any of this Society, now working in various parts of the State as follows: Boston, fourteen; South Frammingham, two; Sherborn Woman's Reformatory Prison, two; Pittsfield, two; Worcester, one; Uitchburg, one; Springfield, one; Mt. Holyoke Seminary, one; Wellesley College, one.

² Vide Report of a meeting of the President and Fellows of Harvard College in Boston, April 3, 1878, and a majority report in favor of accepting the offer of ten thousand dollars signed by Alexander A. Gould, Merrill Wyman, Charles W. Elliot, J. Elliot Lloyd, and a minority report, opposing the plan, signed by Le Baron Russell, May 3, 1879.

president and four of our most accomplished alumni, reported to the overseers in favor of the measure, and the fifth, though not disapproving of the education of women, thought it inexpedient, under present circumstances, to establish female medical instruction. At Harvard, notwithstanding this favorable reply from the body of overseers from which it had sought counsel, the proposition was finally declined by the corporation. This result, it is hinted, was owing to a strong opposition on the part of the Faculty of the Medical School. Doubtless, the sum might have been much augmented, if only the proper *animus* had been exhibited by the corporation and faculty on that occasion. It is not my province, nor would it be becoming on my part, to attempt to mete out the relative blame lying upon the corporation and the medical faculty, that is, between the supreme authority of the university and one of its subordinate departments. Suffice it to say that, by that refusal, Harvard University presents itself to-day before the community as the opponent of the medical education of women. Let me add, too, that the funds thus refused by Harvard were finally transferred to the Homœopathic Medical School of the Boston University, where, if we may trust the statistics given in the last report of that institution, it will be wholly lost, if one may judge from the steady decrease in the number of pupils the past three years.

While Harvard is thus derelict of her higher duties, we hear that her mother university in England now grants diplomas to both sexes in all branches of learning, which she undertakes to teach. We can but hope that her daughter in America will soon, from pure shame if for no other reason, imitate her excellent example.

THE MASSACHUSETTS MEDICAL SOCIETY.

The Massachusetts Medical Society holds, if possible, a worse position than that of Harvard. It is true that the Society itself has never had any opportunity of fully discussing these questions. All discussions, if such they may be called, have generally consisted in cutting off debate and the rejection of proposition looking towards the end proposed. Some discussions, if such they may be called, have been confined to the councilors, and this latter body has shown, of late at its various meetings, a degree of vacillation that is as amazing as it is amusing to all interested in the subject. Their treatment of these matters opens a question as to the liability of the censors to be mulcted by the laws of the State for each and every applicant to whom they have, in consequence of these doings of the councilors, refused examination.

To make this suggestion more clear we must examine what, under the constitution of the Massachusetts Medical Society and the laws of Massachusetts, the censors of the Society are legally bound to do, and their precise liabilities, if they fail to perform their duty.

In the original act of incorporation, passed by the Legislature November 1, 1781, appear the following words in *italics*:—

"Sect. 6. *It is clearly of importance that a just discrimination should be made between those who are duly educated and properly qualified for the duties of their profession and those who may ignorantly and wickedly administer medicine, whereby the health and lives of many valuable individuals may be endangered or perhaps lost to the community.*"

Section 7 gives to the Society the right to appoint

examiners for all applicants who wish to be candidates for the practice of physic, and section 8 imposes a penalty of £100 for obstinately refusing to examine applicants, said penalty to be recovered by such candidate for his own use from any court in Massachusetts, proper to try the same.

The same penalty is continued in the Revised Statutes, 1836, Part I., Chapter 22, Section 5, in a rather more pungent form, as follows: "*If the said censors shall unreasonably refuse to examine any person who is duly qualified for such examination, they shall severally forfeit a sum not exceeding four hundred dollars, to be recovered by such candidate for his own use.*" The italics are my own.

That possible penalty stands now upon the statute book, and although it is by no means certain that any penalty would be imposed upon the censors if the courts of Massachusetts were appealed to, there is no doubt, as I learn from two eminent jurists of this State, that such an appeal could be very properly made by any woman whom the censors have refused. Would our Society, think you, stand higher in the eyes of the public, even if victorious in such a suit? I think not.

It may be asked whether the main body of the Society or the councilors have been the chief cause of this legal liability. The facts are as follows, as I learn from the secretary: "The Society has never voted or had any action upon the subject."

The course of the councilors has been nearly if not quite as follows:—

More than twenty years ago, an accomplished woman physician requested me to appeal to the councilors for examination, and for a license in the usual form.

She asked for it simply in order to stand, under the seal of the Society, as one capable of practising medicine, and to place herself by license of the Society above the herd of ignorant old women then as now infesting the community and claiming to be doctors. She did not ask to be a member of the Society or to attend its meetings. But so important did this license seem to her that she was ready to agree that, if she could not pass the strictest examination by the censors, she would study any length of time they might deem necessary, under teachers whom they might appoint, and promised to do so *until she could* so pass. Certainly nothing could be more loyal to the highest professional ideal, and nothing could be more humble in its request. These propositions, made by one who subsequently proved herself, as I know by consultations with her, to be an able physician, were rejected with scorn and without proper debate by the councilors.

Since that time very little, I think, has been done. The arbitrary vote then and there given absolved me and a few others holding similar opinions from any attention to the supposed requirements of the by-laws, preventing members at that time from consulting with any person outside of the pale of the Society. One or more of the strenuous advocates of our by-laws hinted at possible rebuke, and perhaps our expulsion for thus doing. We only replied, "Do exactly what you wish in the premises," but we thought then, as doubtless the majority of the Society think now, that it would be an evil hour for the Society if any such action were ever taken. We are gratified to find that such illiberal notions would not now be sustained by the highest expounder of by-laws, namely, our actual president, who, at the last meeting of the councilors, took the broad ground

that any member had a right to consult with any physician he might, himself, think duly educated!

After the above action of the councilors, although the subject has been referred to at times, very little if anything further has been accomplished.¹ Many well-educated female physicians have settled in the city. The New England Woman's Hospital, with its corps of physicians and surgeons, and the Woman's Dispensary have been established. There is an increased number of physicians daily consulting with female physicians. But these latter have continued to feel, and, as I think, justly, that the license of the Massachusetts Medical Society would give a certain dignity to their professional position, and, what is more impor-

¹ This remark, though substantially correct, is not strictly true. Through the kindness of Dr. J. R. Chadwick I have been able to obtain the following brief statement of the action of the councilors from the first time that the subject was presented to them. It is a summary of an investigation made by Dr. Hodgden into the records of the councilors. In addition to the story of the doings of the councilors in reference to the admission of women, it fully sustains the statement made in the text that the councilors have usurped powers not granted them by the constitution of the Society, in the fact that they have passed votes ordering the expenditure of money, and instructing the censors, etc., without duly consulting the Society at large.

February 2, 1852. The councilors (on the question of the admission of women to the Society) voted, the censors are directed to examine males only, and the Massachusetts Medical Society would assume any responsibility or expense which the censors might incur (a most extraordinary usurpation of power).

June 4, 1867. To a question from the trustees of the Massachusetts General Hospital the councilors voted that it was inexpedient for our State medical schools or the hospital to admit female medical students. The vote stood, seven affirmative, forty-nine negative.

October 7, 1872. The censors for Suffolk asked what they should do, as they had been requested by a female physician to allow her to be examined for a license to practice and for admission to the Society. A committee was appointed to report February, 1873.

February 5, 1873. Four of the committee were in favor of, one against, granting the request. After discussion the report was recommended to the same committee, with directions to take legal counsel as to the question whether, as the law now stands, women had a right to ask admission.

June 3, 1873. Committee reported in substance as follows from their counsel, E. R. Hoar and George Putnam, Esq.:—

(1.) The Society has a right to say that only males shall be admitted to a license and membership.

(2.) It has never done so by any by-law.

(3.) That in the absence of such by-law the censors have to decide whether sex is a disqualification for the medical or surgical practice.

(4.) That in the absence of any by-law from the Society, if any woman be licensed by the proper officers she is thereby entitled to membership. The censors may reject a woman if they think sex a disqualification for medical and surgical practice.

Upon this report the councilors voted to instruct the censors not to admit women. Carried by a small majority. (The question should have been referred to the Society.)

June 8, 1875. On motion, it was voted to choose a committee of five to report whether duly educated women cannot receive the rights and privileges of membership.

October 5, 1875. This majority reported in favor of examining males and females without distinction. The minority objected to such examination. A long discussion ensued, and an indefinite postponement of the whole matter was carried by a very close vote.

June 11, 1878. A resolution came to the councilors from the Middlesex South District Society desiring that well qualified female practitioners should after examination be admitted. A committee of five was chosen to report at the next meeting.

June 10, 1879. A year afterwards the councilors reported that of the largest number of the committee which could attend a meeting the members were equally divided in opinion. Voted to recommit to the same committee, and with a request to report at the next meeting.

October 1, 1879. The majority of the committee advised no action. The minority reported as follows, that the censors of the Massachusetts Medical Society should be instructed to admit women for examination. The councilors voted, 43 to 38, to adopt the minority report.

February 4, 1880. The censors of Suffolk protested against such instructions unless ratified by the Society. After some discussion, during which a proposition was suggested that an appropriate by-law should be recommended to the Society, it was finally voted that the vote passed October 1, 1879, directing the censors of districts to examine women, be rescinded!

February, 1881. The subject was again brought up by a councilor, and it was laid upon the table.

tant, would place them in more pleasant relations with the whole profession everywhere, not only in Massachusetts but elsewhere. Armed with such certificate of approval by the Society a woman could settle in any town in this country, and, by showing it to physicians resident near her, could prove that they would not degrade themselves by consultation with her.

Accordingly, some time in the autumn of 1879, a number of the female practitioners of Boston applied to the censors of the Society for examination. For months the applicants were devoted students, in addition to attending all their professional practices in the city and vicinity.

Fortunately for the Society, but unfortunately for the applicants, the censors of Suffolk sent in, at the February meeting, 1880, a solemn protest that they could not examine women without the sanction of the Society.¹

But what action did the councilors take on this protest of the censors? Instead of standing manfully to their previously expressed opinion and referring the whole matter to the Society, as we have seen they ought to have done at first, they rescinded their previous vote! Such vacillation is unworthy of the representatives of the profession in Massachusetts. It shows also a determination to keep the subject, if possible, away from the candid consideration of the Society at large.

ACTION OF THE COUNCILORS IN FEBRUARY, 1881.

Under a conviction that injustice had been done, I presented the following resolutions at the last meeting of the councilors, February 10, 1881, with the idea that possibly they might again change their minds, and that the Society, itself, would perhaps then have the question properly submitted to it.

(1.) *Resolved.* That the councilors recommend that the censors be directed to examine women for admission into the Society upon the basis now required for men.

(2.) *Resolved.* That the secretary be hereby directed to present the above vote to the Society at its next annual meeting for action thereupon.

I considered that these resolves were very simple, and I hoped that there could be but little doubt about the propriety of referring them to the Society.

After a very brief but warm discussion and appeals to emotional prejudice, rather than to right and justice, the propositions were very summarily laid upon the table.

PRESENT CONDITION OF THE QUESTION AND PROPOSED REMEDY.

And this is the present condition of the question of the medical education of women, so far as Harvard University and the Massachusetts Medical Society have power and influence on the question. They have both decided that they will do nothing in the premises.

Is this position consistent with reason, justice, or common sense? Nay, is it not degrading to both the

College and the medical Society? I hope you will receive and consider candidly whatever I have said as independent, conscientious thinkers, not as sentimentalists or prejudiced persons. Do not shut your eyes to the facts and think that, by so doing, you can for any length of time check the irresistible onward course of human progress in giving all learning for woman as well as man.

I submit the following propositions and suggestions, hoping that they will commend themselves even to those heretofore opposed to any action in the premises.

(1.) Harvard owes it to herself and to the community to instruct women in medicine.

(2.) Co education, at present, is not advisable, except perhaps in certain departments.

(3.) A separate school for women should be forthwith commenced by Harvard, provided a sufficiently large sum of money can be guaranteed to the corporation to make sure of perfect success.

(4.) Should the medical faculty, either in part or the whole, be unable or refuse to teach, there can be found without doubt in this community many young scientific men, who would be very willing and able to carry on such a school.

(5.) As a new building is to be soon erected for male students, it would seem that a most excellent opportunity is now offered to the College to use the present building for a female medical school.

(6.) The Massachusetts Medical Society should examine women who apply for a license from the Society under the laws of the State, and a diploma should be given to all, who can pass the requisite examination.

(7.) Such diplomas should enable the holders to present themselves before any member of the Society and ask for consultation with him, as any other physician may do.

(8.) This diploma would not necessarily give her the right to attend the meetings of the district, or general society, or to vote on any subject bearing on the organic laws of the same.

(9.) The general society or the district societies might at any time, if the members saw fit to do so, invite women to attend the meetings.

In accordance with these preliminary propositions I present the following resolutions:—

(1.) *Resolved.* That this Society recommends that licenses to practise physic in Massachusetts be hereafter given to those women, who, upon an examination similar to that given to men, are found fully proficient in the principles and practice of medicine.

(2.) *Resolved.* That with such licenses should be given all the rights and privileges granted to men, except those of attending the meetings and of voting upon questions involving the organic laws of the Society.

(3.) *Resolved.* That to each district society and to the general society shall be left the question of extending an invitation to female licentiates to attend their respective meetings.²

(4.) *Resolved.* That in the opinion of the Suffolk District Medical Society it is desirable for Harvard University to establish a medical school for women, and that this course has become necessary if the proper standing of medical instruction is to be kept up in Massachusetts.

(5.) *Resolved.* That the secretary of this Society be

¹ The censors are right in protesting against these repeated usurpations of the councilors, and I heartily thank them for doing so. It is a great pity that it was not made years ago, and then perhaps we should not have lost the valuable old library gathered by our forefathers, and which the councilors had, with bold assurance, given away without asking for the concurrent action of the Society itself, until after the books had been given to the city of Boston and placed in its Public Library. Let us hope that this sharp rebuke from the censors will be a lesson to the councilors to keep within the bounds of their prerogatives, and that it will also teach the Society to look more keenly at the doings of the councilors, and see to it that its laws are not set aside, or its property voted away, without its consent.

² Since writing this paper I learn that eminent legal counsel hold that a license to practice carries with it membership of the Society.

directed to send copies of these resolutions to the councilors of the Massachusetts Medical Society and to the Society itself at the next annual meeting, and likewise to the President and Corporation of Harvard University.¹

THE MECHANISM OF THE CARDIAC AND ARTERIAL TRACES, AND SOME OF THE TEACHINGS OF CARDIO-SPIRYGMOGRAPHY.

BY A. T. KEYT, M. D., CINCINNATI, OHIO.

MECHANISM OF THE CARDIAC TRACE.

In the cardiac cycle there occur as palpable phenomena —

(1.) Auricular systole, with contraction of the auricular fibres, hardening of the auricular parietes, sudden rise of intra-auricular blood pressure, impulsion of blood through the auriculo-ventricular orifice, shrinkage of the auricular volume, and systole quickly changing into —

(2.) Auricular diastole, with relaxation of the fibres, softening of the parietes, sudden fall to negative of the blood pressure, filling of the cavity from the great veins, gradual increase of the blood pressure, swelling of the volume.

(3.) Ventricular systole, with contraction of the fibres, hardening of the parietes, sudden rise of the blood pressure, closure and tension of the auriculo-ventricular valve, opening of the semilunar valves, impulsion of blood through the arterial orifice, reduction of volume, variable maintenance (after the first change) of contraction, hardness, and pressure, and systole suddenly changing into —

(4.) Ventricular diastole, with relaxation of the fibres, softening of the parietes, sudden fall to negative of the blood pressure, opening of the auriculo-ventricular valve, closure of the semilunar valves, filling of the cavity from the auricle, gradual rise by stages of the blood pressure, augmentation by stages of the volume.

(5.) The changes and conditions of arterial filling and emptying.

The elements which determine mainly the formation of the cardiac trace are:—

(1.) Changes of contraction and relaxation of the cardiac fibres.

(2.) Changes of intra-cardiac blood pressure.

(3.) Changes of consistence of the cardiac walls.

(4.) Changes of volume of the heart.

The cardiac trace is produced in man by the instrumental registry of the variations of protrusion and recession of the intercostal space, occasioned by the action and states of the heart beneath. In general terms the space advances and remains more or less elevated during ventricular systole, while it recedes and remains more or less depressed during ventricular diastole.

We will now endeavor to discern the normal types of the individual factors above stated, whose composition must form the true normal cardiogram.

(1.) Systole of the ventricle is marked by contraction of the fibres of the ventricle. At the end of systole the fibres relax, and diastole is marked by relaxation of the ventricular fibres. It is well known that

the ventricle continues for a time to alternately contract and relax, even when its cavity is deprived entirely of blood; yet in normal action it is true that the force and duration of contraction is influenced by the resistance to be overcome. Experiment shows that a stimulated muscle contracts stronger and longer when weighted. So the ventricle will modify its force of contraction by the resistance to the exit of its blood, and will continue its action, within limits, until the object of its systole, the discharge of an adequate volume of blood into the artery, has been fulfilled. Accordingly, then, it is conceived that contraction begins and increases its force until the semilunar valves open and the blood begins to escape. As the blood passes out into the relaxed aorta the resistance diminishes, and with this the force of contraction diminishes; the aorta becoming filled the resistance increases, and with this the force of contraction increases. It seems probable that the arterial resistance is carried back to the ventricle and stimulates its renewed contraction in the form of a double effort, the last one the stronger. Systole being completed, contraction suddenly changes to complete relaxation of the fibres, and the flaccid condition continues throughout ventricular diastole. The module, then, of systolic contraction of the ventricle would be a line first ascending quickly to a high point, then turning a little downwards, then forming a small upward wave, then a wave running as high at least as the level of the first summit; and the module of diastolic relaxation of the ventricle would be a line quickly descending from the high level of the end to the level of the beginning of systolic contraction, and thence running horizontally to the end of diastole. This type is represented in the plate, No. 1., by the line beginning with *a b* and continued by the uppermost dotted line to *a'*. (See next page.)

(2.) The module of intra-ventricular blood pressure is, in systole, closely that of ventricular contraction. Pressure and contraction must begin simultaneously (although the latter is the initial condition), and the elevation of the one and force of the other proceed *pari passu*, and the climaxes be reached at the same time. After the opening of the valves to the end of systole the blood pressure first falls sharply, then is checked and raised a little by the establishment of arterial tension, and then raised more decidedly by the increased force of contraction engendered by the arterial resistance. Thus in strict comparison the waves of blood pressure are sharper than those of contraction, the first fall and second rise of the former *leads* the weakening and strengthening of the latter, while the renewed contraction *leads* in turn the third and last rise of blood pressure. In diastole the blood pressure first descends below zero, then rises by the influx of blood from the auricle, then more slowly by the continued but slower flow, and then more rapidly again by the auricular change. The type, then, of the variations of intra-ventricular blood pressure would be, in systole, a line beginning as with *a b*, then running by the second dotted line to the point intersected by *E*, and, in diastole, continued by *e f*, and thence on to *a'*, nearly by the course of the solid middle line there seen.

(3.) The changes of consistence of the ventricle are a varying hardness during systole and a varying softness during diastole. The varying hardness of systole is the result of changes of contraction and changes of blood pressure combined, and its module is *essentially* that of changes of blood pressure. The varying soft-

¹ For the discussion and the action of the Society on these resolutions see Medical and Surgical Journal, Aug. 4, 1881.

ness of diastole is the result of relaxation and changes of blood pressure combined, and its module is *purely* that of changes of blood pressure. So the line of changes of consistence of the ventricle would be essentially the same as that of variations of intra-ventricular blood pressure before described.

Contraction increases again the rate of reduction. Contraction changing to relaxation, the ventricle suddenly enlarges by lengthening of its fibres and elasticity of its walls, and quick falling into it of blood from the auricle; then the enlargement is slowed, for a time following a slower influx, and next is accelerated again

by the change of auricular systole. Thus the module of changes of volume of the ventricle is typified, in systole, by a line first horizontal, then quickly descending, then more slowly descending, and then again more rapidly descending; in diastole, first quickly, then more slowly, and then again more rapidly ascending. This type is shown in the lowest dotted line running from *a* to *a'*.

Such is our analysis and representation of the phenomena of the movements bearing upon the formation of the cardiac trace. Are these modules correct? They are consistent with accepted physiology of the heart's movements; they are supported in principal features, as self evident propositions, and for the most part they have been confirmed by experiment.¹ With regard, however, to the intermediate systolic wave, it is admitted that other agencies might be adduced as auxiliary factors in its production, and that these agencies might sometimes cause the wave to present in multiple form. These agencies are: (a) locomotion of the heart by back action as the issuing blood meets with resistance; (b) locomotion of the heart by lateral pressure of the pulse wave as it distends the descending aorta; and (c) vibration of the ventricular parietes under the systolic effort and arterial resistance. These factors, if operative, would usually accord in time with the resistance reflected by the interior, and so contribute to the production of the intermediate wave as ordinarily seen; but if, peradventure, they should be discordant, then the wave might appear multiple, as sometimes seen, instead of single.

Accepting, then, the representations given as substantially true, we proceed to seek in the synthesis of these lines the normal type of

the movements of the heart.

We have seen that the modules of contraction, consistence, and pressure resolve themselves essentially into that of intra-cardiac pressure; so the composition sought is substantially between the two lines of pressure and volume, which so far simplifies the investigation.

In the first part of systole, that is, during the pre-

¹ See La Methode Graphique, page 386.

IV. A.T.K. AT REST. AFTER EXERCISE. The changes of volume of the ventricle are reduced by stages during the sphygmie portion of systole, and augmentation by stages during diastole. After the beginning of contraction the ventricle remains at its maximum volume until the blood begins to flow from it actively. The escape, at first free, permits, at first, a diminution in the volume, retarded by the pressure of the blood in the aorta; and the escape is again retarded by the renewed vigor of con-

sphygmie portion, there being no volumetric decline, the intra-ventricular pressure rises without limitation from this cause to its high point of climax, but from this point the line of systole is lower than the line of pressure would make it, in consequence of reduction of ventricular volume; in the oscillations of blood pressure each decline and each elevation mark a lower position, and the level of the end of systole is much below that of the first summit. The diastolic line of recession is shortened in the upper part, and the rest of the line corresponds with that of pressure. The line, then, we would construct from these elements as the module of the heart's pulsation is the solid line *a, b, c, d, e, f, g, h, i, a'*, and this is a real trace of a normal human heart, enlarged to double size by photography.

The module of auricular systole evidently would be composed of contraction of the auricular fibres and intra-auricular blood pressure, and would manifest itself at the surface of the auricle as a single rising and falling wave, appearing a little before the advent of ventricular systole, but over the ventricle this wave would divide itself into two small ones, the first representing the beginning of contraction, and the second the impulsion of blood into the ventricle. Thus the waves *h i* stand respectively for these events.

We maintain that this division of the effect of auricular systole at the surface over the ventricle is favored in sound theory, and the constancy of these small waves in all normal and well-taken cardiograms is confirmatory proof that such is the mechanism of their production.

This cardiogram, taken from a man in health, aged twenty-eight years, is a trustworthy representation of the movements it followed, and is equal to the best specimens of cardiographic art. It shows correctly the phases and limits of ventricular systole and diastole, and the markings of auricular systole. The valvular closures it does not distinctly show. We know that the auriculo-ventricular valve closes in the first part of systole, and the semilunar valves close in the first part of diastole, but these events are drowned, as it were, in the greater events which include them, and transpire, the one whilst the lever is rapidly ascending, the other whilst it is rapidly descending, thus contravening a distinct record of their occurrence. It sometimes happens, however, that a cardiogram of very sloping descent will show a break which marks the closure of the semilunar valves.

MECHANISM OF THE ARTERIAL TRACE.

In the plate the tracing below the cardiac is that of the carotid artery taken simultaneously with the former. It, too, is a typically correct representation of the arterial movements it followed. This trace would differ from a trace of the commencing aorta only in smaller amplitude and a little greater delay on the pulsation of the heart. Allowing only for the latter it may be studied as if it were an actual trace of the initial aorta.

Below is the time in fifths of seconds written by a chronograph also simultaneously with the pulsations. *A A'* are the signal lines made by the levers with the recording slip at rest; *B*, parallel to *A*, cuts the basal point of the cardiac trace which marks the beginning of ventricular systole; and *C*, parallel to *A'*, cuts the basal point of the arterial trace, which marks the beginning of the pulse; *B' C* shows the difference in distance between *A B* and *A' C*, which is the delay of the pulse on the heart, and measured on the chrono-

gram its time-value is neatly found; also *E*, parallel to *A*, cuts the point marking the end of cardiac systole, and *E'*, parallel to *A'*, cuts the pulse trace when it may, the distance *A' E'* being the same as *A E* of the heart line.

Under the systole of the ventricle at the opening of the aortic valves the blood is launched into and expands the artery. Under the charge the climax of arterial tension is soon reached, but is rapidly receded from in consequence of the quick, outward flow of the blood. Thus is formed the first wave of the pulse and first line of recession. The climax of arterial tension is reflected through the open valve back to the heart where it raises a small wave of pressure and excites the ventricle to renewed contraction. This last effort of the ventricle quickly sends forth more or all of the remaining contents staying the arterial recession, and raising a second wave. Thus is formed the second wave of the pulse. Systole being ended and diastole begun, the pressure in the ventricle becomes negative, which starts the arterial current towards the heart, causing rapid recession of the arterial line. This centripetal flow with arterial fall is duly checked by the closure of the aortic valves, and the rebound of the blood completes a third wave. Thus is formed the second line of recession and third or aortic wave of the pulse. (This wave is in fact a double wave, the division arising from the shock of closure and rebound of the blood. I have often traced it on myself, showing the double form.) After this the pulse gradually recedes by the arterial emptying towards the capillaries, and the descending line is thrown into a series of indistinct wavelets, which, if legibly traced, would probably be one for the ventricular filling, one each for auricular contraction and impulsion, and one for the first phase of ventricular contraction, these influences of course transmitted to the closed aorta.

CORRESPONDENCES BETWEEN THE PHASES OF CARDIAC AND ARTERIAL MOVEMENTS.

The arterial line is yet declining when the cardiac ascent begins. This is demonstrated in the tracings in that *B* which marks the basal point of the heart trace cuts the pulse trace at a considerable distance anterior to *C*, the basal point of the latter. It is known that the time occupied by the transmission of the pulse-wave from the aortic orifice to the carotid point is only a small part of the time represented by the distance *B' C*. (The division is indicated by the dotted line between *B'* and *C*.)

The high point of the cardiac trace corresponds closely with the basal point of the arterial. This also is demonstrated in the tracings. The distance *B b* is found to equal the distance *B' C* minus the small distance representing the transit time. Next the arterial line ascends while the cardiac descends, and there is more or less correspondence between the arterial summit and cardiac depression, *c*. The first arterial depression and second wave of the pulse correspond with the remaining part, *c d e*, of cardiac systole. The intermediate cardiac wave *d* fails to appear in the pulse-trace for the reason, probably, that as it is merely a small reflected wave in the heart, its second reflection in the pulse is not apparent. The renewed contraction of the heart would raise a corresponding actual wave, the second wave of the pulse. This correspondence is shown by the relation of the lines *E E'* to these phases, respectively. After this correspondences are no

longer distinctly traced, for although the second arterial notch plainly marks the closure of the aortic valves, this event, as before stated, is not shown in the rapidly falling diastolic line of the heart, and, as previously remarked, the waves of ventricular filling, auricular contraction, auricular impulsion, and initial phase of ventricular contraction, all indicated in the cardiac trace, have but faint and uncertain correspondences in the arterial.

Taking the rise of the pulse as its beginning, the cardiac systolic phase is shorter than the cardiac systole, and the cardiac diastolic phase is longer than the cardiac diastole in either case by so much as the pertaining presphygmie interval.

It is proper to state that the correspondence between the end of ventricular systole and the acme of the second wave of the pulse, although complete in this showing, is liable in other instances to be less exact; the default, however, is never sufficient in frequency or extent to raise a doubt as to the correlation between these events. It sometimes happens that the second pulse-wave attains its point before the end of systole is accomplished, as if the ventricle expelled its blood, and then held its contraction a moment longer. On the other hand, it would seem that the ventricle sometimes changes from systole to diastole before its emptying is completed, and the second wave is sent forward a little delayed on the systolic ending.

OTHER DEMONSTRATIONS.

The illustration before us is a true map in which are correctly shown all the facts of the cardiac and arterial cycle here inscribed, their characters, phases, and relations to each other, and in which the chronometry of the events recorded are shown with mathematical precision.

In addition to phenomena already considered we instance the following showings of durations:—

First cardiac cycle .863 second; systole .323, diastole .540.
Second cardiac cycle .837 second; systole .323, diastole .514.
First cardio-carotid interval .0909 = 1-11 second.
Second cardio-carotid interval .0909 = 1-11 second.
First ventricular presphygmie interval .0555 = 1-18 second.
Second ventricular presphygmie interval .0555 = 1-18 second.
First cardiac systolic phase of pulse .268 second; cardiac diastolic phase .595 second.
Second cardiac systolic phase of pulse .268 second; cardiac diastolic phase .569 second.

The duration of the presphygmie interval was approximately determined in the following way: The carotid-femoral interval in the same subject had previously been ascertained to be .0909 second (unusually long), and on the basis of this the transit interval between the heart and carotid was calculated at .0354 second, and the latter deducted from the cardio-carotid time, difference .0909 second, gave .0555 as the presphygmie interval. The near accuracy of the result so obtained will be apparent when it is considered how closely alike except in lengths are the arterial tracts concerned, and that such similarity would insure uniformity in the rate of propagation of the pulse-wave, and then with correct measurement of the arterial distances and correct observation of the carotid-femoral interval, there could be no room for material error in the estimation of the cardio-carotid transit interval. Relating to these points we have elsewhere¹ treated the presphygmie interval and its variations, and the

velocity of the pulse wave along different parts of the arterial tree.

Another point is the precedence of the auricular to ventricular systole. Measuring from the beginning of the first wave the interval is about two tenths of a second, and from the beginning of the last wave about one tenth of a second. The last wave is that which is usually assigned as answering to auricular systole; but plainly enough this is too close to the systole of the ventricle to include the beginning of auricular contraction, while the first wave is in proper position to mark this event, and the second wave is properly located for marking the event of auricular impulsion.

In accordance with the foregoing views and demonstrations, as well as proven by numerous careful experiments not here recorded, the cardiac and arterial movements and cardio-arterial time-differences are expressed in the graphic lines of the pulsations as follows:—

Of the heart, the initial force of systole (ventricular) is indicated by the height of the main ascent. The quickness of systole by the steadiness of the main ascent. The sustentation of systole by the relative height, as respects the first summit, of the point of systolic ending. The duration of systole by the horizontal distance between successive points of systolic beginning and ending. The duration of ventricular diastole, obviously, by the horizontal distance between successive points of systolic ending and beginning. And the duration of the cardiac cycle by the horizontal distance, preferably, between successive systolic beginnings. Of all these phases and qualities of the heart's pulsation, except the initial force of systole, the graphic lines are true indices without qualification. Regarding the exception, the height of the main ascent is much influenced by other conditions besides the force of systole, as the relation of the heart to the chest-wall, the width and thickness of covering of the intercostal spaces, the position of the subject, all of which in different cases so modify the amplitude of the traces that the height of the upstroke can only be received as an index of systolic energy when other things are known to be equal. Thus the index may be of value in the same individual, but for purposes of comparison between different individuals it must be held of little significance.

The auricles, so far as admissible in view of their position, express their energy of systole by the height of the auricular waves, and their time of systole by the distance between the auricular and ventricular rises.

Of the pulse, the amplitude is shown by the height of the major ascent. The quickness by the steepness of the major ascent. The tension by the relative height and horizontal distance of the second wave and aortic notch from the basal point. The diastole by the height of the aortic wave. The duration or frequency by the distance between successive basal points. The duration of the cardiac systolic and cardiac diastolic portions by the horizontal distances measuring these divisions. All these qualities of the pulse are thus accurately shown, only in estimating the amplitude by the height of the main ascent, regard must be had for the thickness of the tissues over the artery; for plainly of two arteries of the same calibre and movement the more superficial one will afford the higher trace.

Of the cardio-arterial time-differences, these are shown by the difference in distance, from synchronous signals, of the cardiac and arterial basal points, respectively (the synchronous signals are the lines, crossing the traces, made by the levers with the record-

¹ U. S. New York Medical Journal, February, 1878. Cincinnati Clinician, April 13, 1878. Boston Medical and Surgical Journal, April 29, 1880, p. 492.

ing slide at rest as before described) Thus the cardio-carotid time-difference may be found to measure one twelfth of a second, the cardio-radial one sixth of a second, and the cardio-dorsalis pedis one fourth of a second; or, whatever the interval at the moment of observation between the pulsation of the heart and that of any artery, this differential distance mathematically expresses it.

In further illustration of this subject, and to show variations of form and chronometry of the cardiac and arterial movements in health, tracings from three other individuals are produced. They are in *fac-simile* and with the original of enlarged representation just considered were all taken with the compound sphygmograph figured and described in a previous number of this journal.¹

Nos. II. and III. are respectively from young men each twenty years of age. No. IV. is from a man aged fifty-four years; the first part at rest, the last part immediately after active exercise.

The reader who is interested may study at his leisure the indications of these traces, assured that they truly represent the phenomena of cardiac and arterial movements passing in the individuals at the time the observations were made; for the skillful use of our method subordinates the sources of fallacy and gives results whose fidelity withstands the most rigorous tests.

Thus by this method a group of interesting and important facts come easily within our reach — facts physiological and clinical which a few years ago were entirely hidden from view for the want of the proper devices to disclose them; but now that the multiple simultaneous graphic method has been developed and made practical results are already manifest and richest revelations await to reward its freer application.

TWO HUNDRED CASES OF CHOREA.

BY H. C. HAVEN, M. D.

HOPING to find some facts bearing on the pathology of chorea, and particularly on the embolic theory, some time since I examined the records of two hundred cases treated at the Massachusetts General and City Hospital and the Boston Dispensary. Owing to the necessarily incomplete history and record of most who attend an out-patient clinic, little either for or against the embolic theory was elicited. Some other facts, which appeared from the tabulation of these cases, though now in the main universally acknowledged, may be of some slight interest.

SEX.

Females have always been known to be especially susceptible, the ratio between the sexes varying as one male to two, three, or four females. In this series seventy-two were males, one hundred and twenty-eight females, or not quite one to two. Gerhard in eighty cases found the preponderance of females greatest in the second decade, and attributed it to the relatively greater disturbance of the nervous system incident to the establishment and disorders of menstruation. Hasse, however, found in twenty-seven adults, aged from twenty to seventy-six years, quite as large an excess of females, the ratio being 1 to 2.5. Of eighty-eight of this series occurring in the second decade twenty-seven

were males, sixty-one females, or 1 to 2.25, only a slightly larger proportion than in the whole number.

AGE.

Of one hundred and ninety-five in whom the age was noted two were *said* to be congenital, eleven were less than six years old, ninety-two between six and eleven, fifty-eight between eleven and fifteen, twenty-two between fifteen and twenty-one, ten between twenty-one and sixty. These figures agree very closely with other statistics.

SEASON.

Weir-Mitchell and, later, Gerhard have called attention to the number of cases beginning in spring in Philadelphia, and the tendency to relapse during this same season. They attribute it to the enervating influence. Later Dr. Mitchell has called attention to the striking coincidence between the curves of chorea occurrence and the number of storm centres passing within one hundred miles of Philadelphia.

In one hundred and eight cases recorded by Gerhard and Mills sixty-three occurred in spring, thirteen in summer, twelve in fall, twenty-one in winter.

In one hundred and forty-six cases I found seventeen beginning in January, fifteen in February, fifteen in March, sixteen in April, twenty-five in May, thirteen in June, eight in July, nine in August, seven in September, seven in October, five in November, nine in December, or fifty-six in spring, thirty in summer, nineteen in fall, forty-one in winter.

The difference here seems to be much more marked between the first and last months than between the seasons, one hundred and one occurring in the first six months, forty-five in the last six months.

RELAPSES.

Wickes believes relapses are most common in winter, and gives statistics to that effect. Relapses were noted in thirty-one cases of this series: one relapse in twenty-two cases, two in four cases, three in two cases, four in one case, five in one case, seven in one case. Of individual relapses in which the date was given, seven occurred in spring, two in summer, three in fall, seven in winter. Fourteen in the first six months, five in the last six months.

ÆTIOLOGY.

As to the causal relation between chorea and rheumatism, in only forty-two is any mention made of its presence or absence. In twelve cases where the time was accurately noted, rheumatism had preceded the attack at intervals varying from one week to six months. In a number of other cases shifting pains in the joints and limbs were mentioned. These are often regarded as prodromata of chorea. If, however, we consider them as evidence of rheumatism, as in children it might be done with considerable fairness, the number would be much increased over the forty-two mentioned above. The occurrence of a cardiac murmur was rarely noted, it apparently not being considered of much import at the time many of the records were made.

In two cases chorea was associated with the puerperal condition; in one of these acute mania was a concomitant. Psychological influences were considered responsible in comparatively few cases. Fright in seven

¹ May 20, 1880, page 484.

association with choreics three, sudden plunge in cold water (tright?) two.

As having a certain bearing on the cerebral localization of the lesion and to a certain extent the embolic theory, the seat of the choreic motion and affection of speech are interesting. Out of thirteen cases in which the speech was said to have been affected, I found the right side was alone affected or became so first and remained the worse in ten. One case is particularly interesting; the movements began on the left side, and were confined there for some days. The right side then became implicated, and simultaneously the speech, which had been perfect before, became much impaired. In three of the thirteen the left side was alone or first attacked. One of these is also interesting: in a previous attack the left side alone was affected, and the speech was much impaired; during the last attack the right side alone was affected, and the speech remained perfect.

In sixty-six the seat of motion was definitely noted: seventeen with right hemichorea, ten with left hemichorea, twenty beginning on right side afterwards universal, but remaining worse on the right, eight same on left side, five universal mostly right, one universal mostly left; one began on left side, became universal, but worse right. Thus fifty were entirely or worse on the right side, sixteen entirely or worse on the left side.

DURATION.

This was exactly stated in but few cases. In twenty-five the average was 94.5 days; in seven of the twenty-five, treated by arsenic alone, it was 77 days. These numbers are, of course, too small to have any value, but are interesting in view of the facts recorded by Gray and Tuckwell, who found the duration of six and twelve cases, treated on the purely expectant method, to be 72 and 73 days, respectively. Gray found an average duration of 75 days in seven cases treated with different remedies, and Tuckwell of 76 days in ten cases where arsenic alone was given.

RESULT.

Three fatal cases occurred in this series.

REPORT ON PROGRESS OF THERAPEUTICS.

BY ROBERT AMORY, M. D. (HARV.), LONGWOOD, BROOKLINE.

THE ACTION OF DIGESTIVE FERMENTS.

M. A. Petri¹ conducted certain experiments upon the digestive properties of ferments, and the following summary contains a pretty fair synopsis of his work:—

(1.) That the best test of the digestive properties of a given ferment are dependent upon the fact of a total transformation into peptones of a determined weight of fibrin.

(2.) The simple solution of fibrin is but a small and insignificant portion of the action of pepsin.

(3.) It is possible to prepare pepsins which have the power of converting a thousand times their weight of fibrin into peptones, and of dissolving in a few hours five hundred thousand times their weight of fibrin.

(4.) Pepsin is a nitrogenous body resembling the composition of albuminoid materials.

(5.) Certain bodies which have a strong action upon alcoholic fermentation and upon the fermentation of diastase, such, for instance, as sulphurous acid, have apparently no peptic fermentative properties.

(6.) There is no equivalent action between the different acids in point of view of their action upon albuminoid matters, some of them being almost inert, such as acetic, butyric, and valerianic acids.

(7.) Most salts have no specific action upon peptic fermentation; some, such as acetates, butyrates, valerianates, phosphates, etc., can, however, assist in the process of digestion by substituting in the formation of hydrochloric acid, and are more or less active according to the amount of this acid produced by the decomposition of their salts.

(8.) Emetics do not act in doses beyond those which are medicinal.

(9.) Alkaloids have no specific action.

(10.) The addition of certain salts in a small quantity (particularly that of sodium chloride) enfeeble the action of pepsin.

(11.) Sugar, even in large amount, does not hinder the action of pepsin; the use of this substance in form of syrup being perfectly rational.

(12.) The digestive properties of an aqueous solution of pepsin are not in the least hindered when a volume of twenty per centum is added to it. If the volume of alcohol is below five per centum, the pepsin will preserve all its activity, will transform the fibrin into peptones and will dissolve rapidly coagulated albumen at a temperature of 42° C.

(13.) Preparations in form of elixirs will preserve for a long time (nearly four years) their digestive properties.

(14.) Upon the principle that a solution of pepsin in dilute alcoholic liquors will retain its action when agreeably diluted it follows, in a therapeutic sense, that the proscription of the employment of a pure wine during repast is not rational, and the small quantity of alcohol introduced into the stomach in the form of wine or elixir can be absolutely neglected.

(15.) The alcoholic strength of table wines varies from eight to ten per centum, and sometimes even as low as two to five per centum, according to the quantity of water added. The favorable conditions of peptonic activity are therefore found in this case, and it is unnecessary to explain, as do some experimenters, this apparent innocency in the use of mild wines during repast to the very rapid absorption of alcohol (this absorption taking place in half an hour, and in the case of milk in one hour).

(16.) The substances really incompatible, and which have almost a specific action upon pepsin, are bromine, iodine, chloral, salicylic acid, gallo-tannic acid, and, in a slighter degree, benzoic acid, phenol, or phenic acid.

DIGESTIVE ACTION OF PAPAYA AND ITS ALKALOID PAPAIN ON LIVING TISSUES.²

Bouchut, in continuation of his experiments on the digestive properties of papaya and its derivative papain, which proved that this substance converted proteic materials, such as fibrin, gluten, and milk, into peptones, has found: that the juice of papaya and its alkaloid papain placed upon an exposed brain in a living animal caused the digestion of those portions of the cerebral tissues which were in contact, and that the animal became collapsed in two or three hours, and that the mus-

¹ *Journal de Thérapeutique*, February, July, 1880.

² *Archives Gen. de Médecine*, Juillet, 1880.

cles on one or both sides were paralyzed? A gramme of this juice injected into the muscular tissue caused its degeneration into a pulpy, gelatinous condition. So, also, when it was placed on pathological tissues would a similar degeneration follow. The apposition of the same drug upon adenomata and cancerous surfaces would convert these tissues into a digested peptone precisely similar to dead tissues. He suggests the therapeutic value of this drug in diseased tissues.

NITRITE OF AMYL; ITS PHYSIOLOGICAL ACTION.

Filehne¹ concludes, from a series of experiments, in which he performed a ligation of carotids, that amyl-nitrite, in dilating the capillaries and reducing the blood tension, acts by means of the central nervous system and not by the sympathetic, for it causes a suppression of action or a paralysis of the nerve centres, so that an animal affected by the inhalation of this vapor is like one in which there is no central nervous action upon the vaso-motor nerves. Probably the action upon these latter is due to a paralysis of the contracting (or constricting) muscles of the arteries. The acceleration of the heart's action is not, in his opinion, due entirely to a paralysis of the pneumogastric nerve. Filehne also attributes the toxic effects of amyl-nitrite, such, for instance, as the dyspnea and convulsions, to a diminution of arterial tension, and also to a deprivation of oxygen in the blood circulation, and a destruction of the oxy-haemoglobine. The medulla oblongata then, without an oxygenated blood, causes trouble in the respiratory movements and convulsions.

The use of phosphates in pulmonary phthisis has been investigated by Dr. Stokvis² with the following conclusions:—

(1.) The elimination of phosphoric acid by the kidneys in phthisis is not recognized in a diagnostic or pathological sense, because the total amount of phosphoric acid eliminated with the urine in twenty-four hours is not increased either at the beginning or at the end of phthisical cases. In cases of phthisis as compared with other pulmonary diseases phosphoric acid elimination is diminished, though in certain chronic cases of phthisis unassociated with fever or diarrhoea the earthy phosphates were comparatively in larger amount than the alkaline phosphates, yet even in these cases this amount in twenty-four hours was less than the average in healthy urine or in that from certain other diseases, as, for instance, that of phosphaturia, diabetes mellitus, and renal diseases. The elimination of phosphoric acid in phthisis does not show any constant deviation from the normal as compared with the amount of urea, the relative amount being usually diminished, and yet this relative amount may be slightly increased when compared with the chlorides eliminated. This latter increase is more marked in complications of fever and imperfect digestion, especially when associated with inanition, hence it is fair to suppose that the relative increase as compared with the chlorides is due to the deficiency of the latter. Comparisons of elimination of phosphoric and sulphuric acid shows first that the relative amounts are not very remarkable, and that when observed it is probably due to an increase in the amount of sulphates in the urine, which fact is not uncommon in prolonged fever and in emaciation. Therefore the variations in amount of phosphoric acid elimination met with in cases of pul-

monary phthisis are specifically due both to a greater or less degree of animal temperature and to interference with the digestive functions and to dietetic disturbances or faulty nutrition. Hence it follows that any improvement which is noticed in the treatment of phthisis by the phosphates and hypophosphites should be explained by the fact that an extra supply of phosphoric acid is furnished to the organism to make up for the losses occasioned by the elimination of the phosphates by the kidneys. Salicylic acid is most conveniently administered to rheumatics, according to Dr. Thomas,³ by its combination with acetate of potassa in the following formula:—

Rx	Potass. acetat.	ij.
	Acid salicylic	ss.
	Aq. menth. piper	iv.
	Syrup limonis	ij. M.

The potassa acetate should be rubbed up in a mortar with the peppermint water, the acid being gradually mixed with it until perfectly dissolved. The dose is half an ounce of the solution every two, three, or four hours or oftener, according to the violent symptoms, or about twenty grains of the acid with eighty grains of acetate of potassa. The advantages of this mixture consist in not disturbing digestion, that it is palatable, that the salicylic acid is well dissolved, that no bad effects upon the heart are observed, being even less depressing than salicylate of soda, and that it is an efficient method of treatment. In vigorous patients Dr. Thomas employs one eightieth to one sixtieth of a grain of atropia with or without morphia to allay pain. His experience leads him to expect convalescence in five or six days. It is well to remark here that certain Boston physicians, among them the present reporter, almost always have employed, the past three years, salicylic acid in solution with liquor potassa acetatis to which a little peppermint is added; the addition of lemon syrup would seem to assist in dissolving the salicylic acid.

OFFICIAL BULLETINS OF THE PRESIDENT'S CASE.

OUR readers will find below a reproduction of the official bulletins issued by President Garfield's attending surgeons; they offer by themselves an interesting study, and they will prove in this form convenient for reference. Appended to the bulletins will be the account of the autopsy and a chart of pulse and temperature which we have taken pains to compile. Slight differences will be found between any two records of temperature, as the telegrams issued at noon often differed from the *résumé* given to the consulting surgeons at night, according to published reports.

EXECUTIVE MANSION.

WASHINGTON, D. C., July 2, 1881, 11 P. M. }

The President is resting quietly, and is cheerful. Pulse 124, temperature 99°, respiration 20. All the symptoms are favorable.

EXECUTIVE MANSION.

WASHINGTON, D. C., July 3, 1881, 1 A. M. }

The improvement in the President's condition, which began early in the evening, has steadily continued up to this hour. His temperature and respiration are now normal, and his pulse has fallen to 120. The attending physicians regard all his symptoms as favorable, and a more hopeful feeling prevails.

¹ Arch. für Anat. u. Phys., pages 385-416, 1879.

² Archives Gen. de Médecine, June, 1880.

³ American Practitioner, May, 1880.

10 P. M. The condition of the President is less favorable. Pulse 120, temperature 100°, respiration 20. He is more restless, and again complains of the pain in his feet.

EXECUTIVE MANSION, }
WASHINGTON, D. C., July 4, 1881, 12.30 A. M. }

The President's condition is changed very little since the last bulletin. Pulse 112, temperature 99.8°, respiration 20. Some tympanites is recognized. Does not complain so much of pain in the feet.

8.15 A. M. The condition of the President is not materially different from that reported in the last bulletin (12.30 A. M.). He has dozed at intervals during the night, and at times has continued to complain of the pain in his feet. The tympanites reported has not sensibly increased. Pulse 108, temperature 99.4°, respiration 19.

We held a consultation with the physicians in charge of the President's case at 7 this morning, and approve in every particular of the management and the course of treatment which has been pursued.

FRANK H. HAMILTON, of New York.
D. HAYES AGNEW, of Philadelphia.

1 P. M. There has been but little change in the President's condition since the last bulletin. He complains much less of the pain in his feet; slight vomiting occasionally. Pulse 110, temperature 100°, respiration 24.

7.45 P. M. The President this evening is not so comfortable. He does not suffer so much from pain in the feet. The tympanites is again more noticeable. Pulse 126, temperature 101.9°, respiration 24. Another bulletin will be issued at 10 P. M., after which, in order not to disturb the President unnecessarily, no further bulletins will be issued until to-morrow morning.

10 P. M. Slight ameliorating symptoms during past two hours. No vomiting during that period. Pulse 104, temperature 101°, respiration 24. In order not to disturb the President unnecessarily, no further bulletins will be issued until to-morrow morning.

TO LOWELL, Minister, London:—

An important consultation was held this morning, at which Dr. Agnew, of Philadelphia, and Dr. Hamilton, of New York, able and skillful surgeons, were present. The result is not reassuring, though the conclusion was that recovery is possible. We do not give up hope.

BLAINE, Secretary.

EXECUTIVE MANSION, }
WASHINGTON, D. C., July 5, 1881, 8.30 A. M. }

The President has passed a comfortable night, and his condition this morning is decidedly more favorable. There has been no vomiting since last evening at 8 o'clock, and he has been able to retain the liquid nourishment administered. There is less tympanites, and no abdominal tenderness except in the wounded region. Pulse 114, temperature 100.5°, respiration 24.

12.30 P. M. The favorable condition of the symptoms reported in the last bulletin continues. There has been no recurrence of the vomiting. Pulse 110, temperature 101°, respiration 24. The President lies at present in a natural sleep. No further bulletins will be issued till 8.30 P. M., unless in case of an unfavorable change.

8.30 P. M. The condition of the President continues as favorable as at the last bulletin. Pulse 106, temperature 100.9°, respiration 24. No further bulletins will be issued till to-morrow morning, unless in case of an unfavorable change.

TO THE CONSULTING SURGEONS.—9.30 P. M.

After you left, urgent symptoms continued. There was much restlessness, constant slight vomiting, and by 8 o'clock P. M. the President's condition seemed even more serious than when you saw him. Since then his symptoms have gradually become more favorable. There has been no vomiting or regurgitation of fluid from the stomach since 8 o'clock last evening. The President has slept a good deal during last night and this morning, and expresses himself as comparatively comfortable. The spasmodic pains in the lower extremities have entirely disappeared, leaving behind, however, much muscular soreness and tenderness to the touch. There is less tympanites and no abdominal tenderness whatever except in the hepatic region. Since 8 P. M. he has taken an ounce and a half of chicken broth every two hours, and has retained it all. The wound was again dressed antiseptically this morning. Altogether, but half a grain of morphia has been administered hypodermically the last two or four hours, and it has been found quite sufficient. His pulse, however, still keeps up. At 8.30 A. M. it was 115, temperature 99.5°, respiration 24. Seventy-two hours have now

elapsed since the wound was received. We cannot but feel encouraged this morning, although, of course, we do not overlook any of the perils that still beset the path toward recovery. The course of treatment agreed upon will be steadily pursued.

EXECUTIVE MANSION, }
WASHINGTON, D. C., July 6, 1881, 8.30 A. M. }

The President has passed a most comfortable night, and has slept well. His condition has remained throughout as favorable as when the last bulletin was issued. The pulse is becoming less frequent, and is now 98, temperature 98.9°, respiration 23.

12.30 P. M. The President remains quite as comfortable as at the date of the last bulletin. He takes his nourishment well. Pulse 100, temperature 99.7°, respiration 23.

8.30 P. M. The President's condition continues as favorable as at last reports. He has passed a very comfortable day, taking more nourishment than yesterday. Pulse 104, temperature 100.6°, respiration 23. Unless unfavorable symptoms develop, no further bulletins will be issued until to-morrow morning.

TO THE TWO CONSULTING SURGEONS.—1 P. M.

Since our telegram of yesterday the case has continued to make favorable progress. The President was quite comfortable during the day, and needed no morphine until bed-time last night. His mind was perfectly clear, but he obeyed our injunction to refrain from conversation. The afternoon exacerbation of symptoms, heretofore observed daily, did not occur. On the contrary, a slight diminution in the pulse took place. By 8.30 P. M. it was 106, temperature 100.0°, respiration 24. During the afternoon he had several small, solid, natural evacuations from the bowels, the first since the accident. They occurred without pain or discomfort, and contained no trace of blood. During the early evening, from 7 to 10 P. M., he was troubled occasionally by acid eructations, but on suspending the administration of nourishment for a time this symptom disappeared. At 10.30 P. M. one quarter of a grain of morphine was administered hypodermically, being the only morphine given since our telegram to you yesterday. He slept very well during the night, and expressed himself as feeling quite comfortable, though weak, this morning. At 8.30 this morning his pulse was 98; temperature 98.9°; respiration 23. The tenderness of the lower extremities to the touch has considerably diminished. He is taking with relish every two hours some chicken broth, made more nutritious by the addition of raw egg albumen. At 12.30 P. M. to-day his pulse was 100, temperature 99.7°, respiration 23. Will continue to keep you advised of the progress of the case.

EXECUTIVE MANSION, }
WASHINGTON, D. C., July 7, 1881, 9.15 A. M. }

The President passed a most comfortable night and continued steadily to improve. He is cheerful and asks for additional food. Pulse 94, temperature 99.1°, respiration 23. There will be no further bulletin issued until 1 o'clock.

The 1 o'clock bulletin was to the effect that the patient's condition was quite as favorable as in the morning, his pulse being 100, temperature 100.8°, and respiration 23.

8.30 P. M. The favorable condition of the President continues. Pulse 106, temperature 100.2, respiration 25. Unless some unfavorable change occurs no further bulletin will be issued until to-morrow morning.

TO THE CONSULTING SURGEONS.—1 P. M.

During the past twenty-four hours the President has continued to improve slowly. As was anticipated, a slight rise of temperature and slight increase in the frequency of the pulse occurred during the afternoon and evening. At 8.30 P. M. the pulse was 104, temperature 100.6°, respiration 23. But in accordance with this diurnal movement both pulse and temperature were again diminished this morning, and showed some improvement over yesterday at the same hour. At nine A. M. the pulse was 94; temperature 99.1°; respiration 23. We anticipate, of course, a similar movement for some days to come, and so to-day find at 1 P. M. the pulse 100, temperature 100.8°, respiration 23. Last evening, at 9.30 P. M., a quarter of a grain of morphia sulphate was administered hypodermically, and the President slept very well during the night. In addition to the chicken broth and albumen, he had yesterday afternoon a small quantity of scraped beef tenderloin which, however, he did not relish very much. This morning he is taking oatmeal gruel and milk at intervals of two hours with relish. Yellowishness of the skin, so common after wounds of the liver, developed to a slight degree during the day yesterday, but is not more marked this morning. We do not attach a great deal of importance to this symptom except so far as to confirm the opinion already formed of the na-

ture of the wound. Altogether we feel that the patient has done as well as could reasonably have been expected up to the present time, and our hopes of his ultimate recovery are strengthened by the events of the last two days.

EXECUTIVE MANSION, }
WASHINGTON, D. C., July 8, 1881, 8.15 A. M. }

The condition of the President continues favorable. He is more comfortable than on any previous morning. Pulse 96°, temperature 99.2°, respiration 23. The wound is beginning to discharge laudable pus.

A bulletin at 12.30 p. m. stated that the patient's condition continued to be favorable, pulse 108, temperature 101.4°, respiration 24.

8 p. m. The President's condition continues favorable. He has passed a very comfortable afternoon, and has taken more nutriment than on previous days. Pulse 108, temperature 101.3°, respiration 24.

TO THE CONSULTING SURGEONS. — 3 P. M.

The President's condition has not changed materially since our telegram to you yesterday. During the afternoon and evening he was again troubled with acid eructations and the administration of nutrients was again suspended for several hours. One quarter of a grain of morphia was administered hypodermically at 8.30 p. m., and followed at once by tranquil sleep. Towards midnight, however, he became restless, and complained a good deal of muscular soreness in the feet, and of pain in the ankle-joint, so that we were on the point of administering an additional anodyne when he fell asleep, and on awaking was so free from pain that it was not given. After 1 A. M. he passed the night tranquilly, sleeping composedly most of the time. At intervals since that hour he has taken an ounce of the albumenized chicken broth, alternating with an ounce of milk, to which a teaspoonful of old and excellent rum was added; all this has been retained, as well as five grains of sulphate of quinia taken this morning at 8 A. M. The yellowish tinge of the skin, mentioned in our last telegram, has sensibly diminished. When the antiseptic dressing was renewed this morning the wound was found to be discharging a small quantity of healthy-looking pus. The reaction accompanying the establishment of suppuration is, as might be expected, marked by a slight rise in temperature and pulse as compared with the corresponding hours of yesterday. This, however, we do not regard as unfavorable under the circumstances, and should not be surprised if it continued through this afternoon, and were repeated in the afternoon and evening for several days. The record since our last telegram is as follows: Yesterday, at 8.30 p. m., pulse 106, temperature 100.2°, respiration 23. This morning, at 8.30 A. M., pulse 96, temperature 99.2°, respiration 23; at 1 p. m. it was pulse 108, temperature 101.4°, respiration 24.

EXECUTIVE MANSION, }
WASHINGTON, D. C., July 9, 1881, 7.15 P. M. }

The President's condition has continued favorable during the day. The febrile reaction does not differ materially from that of yesterday. Pulse 108, temperature 101.9°, respiration 24.

TO THE CONSULTING SURGEONS. — 1 P. M.

The President continues to improve slowly. The acid eructations have not recurred during the last twenty-four hours. An ounce of milk, with a teaspoonful of rum, has been taken every two hours during the day, and at longer intervals during the night, without producing any gastric embarrassment. At 9 A. M. to-day he took nine grains of bisulphate of quinia, which did not disturb the stomach. Yesterday, towards evening, he became restless, wearied, and anxious for the morphia, and a quarter of a grain was given hypodermically at 8.30 p. m., after which he passed a tranquil night, sleeping most of the time. Yesterday afternoon he had a small, solid passage from the bowels, in which a notable deficiency of biliary coloring matter was observed. The yellowish tinge of the skin continues about as last report. At 8 p. m. the pulse was 108, temperature 101.3°, respiration 24. This morning at 1.30 the pulse was 100, temperature 99.4°, respiration 24. At 10 p. m., pulse 104, temperature 101.2°, respiration 22.

EXECUTIVE MANSION, }
WASHINGTON, D. C., July 10, 1881, 8 A. M. }

The President has passed the most comfortable night he has experienced since he was wounded, sleeping tranquilly and with few breaks. The general progress of his symptoms continues to be favorable. Pulse 106, temperature 100°, respiration 23.

A bulletin at 1 o'clock, p. m., stated that the patient's symptoms continued to be favorable. Pulse 102, temperature 100.5°, respiration 22.

7 p. m. The President's symptoms continue to make favorable progress. Pulse 108, temperature 101.9°, respiration 24.

TO THE CONSULTING SURGEONS. — 3 P. M.

Such slight changes as have taken place in the President's condition since our telegram of yesterday are of a favorable character. About 7 p. m. his bowels were freely moved. Shortly afterwards he received a hypodermic injection of one quarter of a grain of morphia. He slept more naturally during the night than he has done since he was hurt, and this morning is comfortable; takes his nourishment well, and appears on the whole better than hitherto. During the last twenty-four hours he has taken altogether fourteen ounces of milk and one ounce of rum. This morning at 10.30 he again received ten grains of bisulphate of quinia. Both yesterday and the day before the wound was dressed antiseptically twice during the twenty-four hours. This morning it is discharging rather less pus than yesterday, but its appearance is healthy. Yesterday, at 7.15 p. m., his pulse was 108, temperature 101.9°, respiration 24. To-day, at 8 A. M., pulse 106, temperature 100°, respiration 23. At 1 p. m., pulse 102, temperature 100.5°, respiration 22.

EXECUTIVE MANSION, }
WASHINGTON, D. C., July 11, 1881, 8 A. M. }

The President has passed a comfortable night, and his condition shows an improvement over that of yesterday. Pulse 98, temperature 99°, respiration 22.

The bulletin at 1 o'clock stated that the favorable progress of the President's case continued. His pulse at that time was 106, temperature, 99.8°, respiration 24.

7 p. m. The President has had rather more fever this afternoon. In other respects his condition is unchanged. Pulse 108, temperature 102.8°, respiration 24.

TO THE CONSULTING SURGEONS. — 1 P. M.

During the last twenty-four hours the favorable progress of the President's case has continued. He has taken and retained twenty-two ounces of milk and one ounce of rum. This morning at 9 A. M. he had, besides, a slice of toast softened in milk, and at 11.15 he took fifteen grains of bisulphate of quinine. There has been no irritability of stomach at any time. Last evening at 7.15 he received one quarter of a grain of morphia sulphate, hypodermically, and slept well during the night. The wound was again dressed antiseptically yesterday evening and this morning, and continued to discharge a small quantity of pus. Last evening at 7 p. m. his pulse was 108, temperature 101.9°, respiration 24. This morning at 8 o'clock, pulse 98, temperature 99.2°, respiration 22. At 1 p. m. pulse 106, temperature 99.8°, respiration 24.

EXECUTIVE MANSION, }
WASHINGTON, D. C., July 12, 1881, 9 A. M. }

The President is comfortable this morning. The rise in temperature noted in last evening's bulletin began to diminish about an hour later. Pulse 96, temperature 99.6°, respiration 22.

The second bulletin, at 1 o'clock, stated that the President was passing a comfortable day. His pulse at that hour was 100, temperature 100.8°, and respiration 24.

7 p. m. The President has passed a much more comfortable day than yesterday. Pulse 104, temperature 102.4°, respiration 24.

TO THE CONSULTING SURGEONS. — 1 P. M.

During the afternoon yesterday the President's temperature rose to the highest point it has yet attained. It began to fall, however, immediately after he received his evening morphia, one quarter of a grain of the sulphate hypodermically, and this morning corresponds with previous days. About 6 p. m. he had a consistent and copious movement of the bowels. His wound was dressed antiseptically yesterday evening and this morning. He continues to retain all the nourishment prescribed him, and has had twenty-four ounces of milk and one of rum during the last twenty-four hours, besides a small quantity of milk toast this morning. At 8.30 this morning he also received ten grains of bisulphate of quinia. His general condition this morning appears to us rather better than yesterday morning. Last night at 7 o'clock his pulse was 108, temperature 102.8°, respiration 24. This morning at 8 o'clock, pulse 96, temperature 99.6°, respiration 22. At 1 p. m., pulse 100, temperature 100.8°, respiration 24.

EXECUTIVE MANSION,
WASHINGTON, D. C., July 13, 1881, 8.30 A. M. }

The President is doing well this morning. Pulse 90, temperature 98.5°, respiration, 20. His gradual progress towards recovery is manifest, and thus far without serious complications.

7 P. M. The President has had less fever this afternoon than either yesterday or the day before. He continues slowly to improve. Pulse 100, temperature 101.6°, respiration 24.

TO THE CONSULTING SURGEONS.—1 P. M.

The febrile rise yesterday afternoon was less marked and occurred at a later hour on the previous day, and to-day for the first time the President's morning temperature fell to the normal point. The general progress of his symptoms appears more favorable than hitherto. During the last twenty-four hours he has taken thirty-two ounces of milk and one ounce of rum. This morning he had also a slice of milk toast and chewed the breast of a woodcock, but did not care to swallow the meat. He had last night one-quarter of a grain of sulphate of morphia hypodermically (in no twenty-four hours during the past week has he received more than a single dose of this quantity), and slept well during the night. This morning he received ten grains of the bisulphate of quinia. Yesterday at 7 P. M. his pulse was 104, temperature 102.4°, respiration 24. To-day, at 8.30 A. M., pulse 90, temperature 98.5°, respiration 20. At 1 P. M., pulse 94, temperature 100.6°, respiration 22.

EXECUTIVE MANSION,
WASHINGTON, D. C., July 14, 1881, 8.30 A. M. }

The President has passed a comfortable night, and continues to do well. Pulse 90, temperature 99.8°, respiration 22.

The 1 o'clock bulletin states that the progress of the President's case continued to be satisfactory. His pulse at that hour was 95, temperature 98.5°, respiration 22.

7 P. M. The febrile rise this afternoon has been less pronounced, and has not caused the President so much discomfort. His general condition is good. Pulse 98, temperature 101°, respiration 23.

TO THE CONSULTING SURGEONS.—1 P. M.

The President has continued to progress favorably during the last twenty-four hours. The febrile rise yesterday afternoon was again less than on the previous day. He has taken since our last telegram twenty-nine ounces of milk, with an ounce of rum, in divided dose as heretofore, besides a small slice of milk toast this morning, and at noon to-day a small sandwich of scraped raw beef, with two teaspoonfuls of Valentine's beef juice and an ounce of Tokay wine of 1868. The medication has consisted of a single hypodermic injection of one-quarter of a grain of sulphate of morphia, given last night, and ten grains of bisulphate of quinia at 8 A. M. to-day. We administered yesterday at 5 P. M. an enema of soap and water, which was promptly followed by a copious movement of normal consistence and color. At 7 P. M. his pulse was 100, temperature 101.6°, respiration 24. To-day at 8.30 A. M., pulse 90, temperature 99.8°, respiration 22. At 1 P. M., pulse 94, temperature 98.5°, respiration 22.

EXECUTIVE MANSION,
WASHINGTON, D. C., July 15, 1881, 8.30 A. M. }

The President has rested well during the night, is doing admirably this morning, and takes his food with relish; pulse 90, temperature 98.5°, respiration 18.

7 P. M. The President has passed a better day than any since he was shot. The afternoon fever is still less than yesterday. At 1 P. M. his pulse was 94, temperature 98.4°, respiration 18. His pulse is now 98, temperature 100.2°, respiration 19.

EXECUTIVE MANSION,
WASHINGTON, D. C., July 16, 1881, 8.30 A. M. }

The President has passed another good night, and is steadily progressing towards convalescence. Pulse 90, temperature 98.5°, respiration 18.

7 P. M. The President has passed a better day than any since he was shot. The afternoon fever is still less than yesterday. At 1 P. M. his pulse was 94, temperature 98.4°, respiration 18. His pulse is now 98, temperature 100.2°, respiration 19.

EXECUTIVE MANSION,
WASHINGTON, D. C., July 17, 1881, 7 P. M. }

Our expectations of favorable progress have been fully realized by the manner in which the President has passed the day. He has taken more solid food, and with greater relish, than hitherto, and his afternoon fever, which is as slight as that of yesterday, came on later. At 1 P. M. his pulse was 94, temper-

ature 98.5°, respiration 18. At present: pulse 98, temperature 100.2°, respiration 20.

TO THE CONSULTING SURGEONS.—7 P. M.

Since our dispatch of yesterday the President has done as well as our hopes then indicated. He has had a single hypodermic injection of one eighth of a grain of sulphate of morphia (at bedtime), and slept well. Quinia in three-grain doses has been continued, as has also the plan of nourishment heretofore reported. His bowels have been kept free by enemata. The wound is dressed, with antiseptic precautions, twice daily. There is now a free discharge of healthy pus. The afternoon fever, both yesterday and to-day, has been comparatively slight. Yesterday, at 1 P. M., his pulse was 94, temperature 98.5°, respiration 18. At 7 P. M., pulse 98, temperature 100.2°, respiration 19. To-day, at 8.30 A. M., pulse 90, temperature 98.4°, respiration 18. At 1 P. M., pulse 92, temperature 98.5°, respiration 18. At 7 P. M., pulse 98, temperature 100°, respiration 20.

EXECUTIVE MANSION,
WASHINGTON, D. C., July 18, 1881, 8.30 A. M. }

The President has passed another comfortable night, and is doing well this morning. Pulse 88, temperature 98.4°, respiration 18.

A bulletin at 1 o'clock stated that no material change in the President's condition has occurred since morning. At that hour he was resting quietly, his pulse being at 90, temperature and respiration normal.

7 P. M. The President has had a little more fever this afternoon, which is regarded as merely a temporary fluctuation. At 1 P. M. his pulse was 98, temperature 98.5°, respiration 18. At present his pulse is 102, temperature 100.7°, respiration 21.

TO THE CONSULTING SURGEONS.—7 P. M.

Shortly after our dispatch of yesterday the President received a hypodermic injection of one eighth of a grain of sulphate of morphia. He slept well during the night, and this morning at 8.30 had a pulse of 88, temperature 98.4°, respiration 18. His day, however, was not quite so comfortable as yesterday. Slight gastric disturbance was noted toward noon, in consequence of which the quantity of nourishment administered was temporarily diminished. This was followed by rather more afternoon fever than yesterday, but the difference was not great, and is thought to be merely a temporary fluctuation. At 1 P. M. his pulse was 98, temperature 98.5°, respiration 18. At 7 P. M., pulse 102, temperature 100°, respiration 21.

EXECUTIVE MANSION,
WASHINGTON, D. C., July 19, 1881, 8.30 A. M. }

The President has passed a very good night, and this morning he is free from fever, and expresses himself as feeling quite comfortable. Pulse 90, temperature 98.5°, respiration 18.

7 P. M. Last evening the President received a hypodermic injection of one eighth of a grain of morphia, and slept well during the night. He continues to take sulphate of quinia in three-grain doses thrice daily, and has enemata when required. As anticipated, the increased fever of yesterday proved only temporary, and he has had a better day to-day than any since he was injured. This morning at 8.30 his pulse was 90, temperature 98.4°, respiration 18. At 1 P. M. pulse 92, temperature 98.5°, respiration 19. At 7 P. M. pulse 98, temperature 99.8°, respiration 19.

EXECUTIVE MANSION,
WASHINGTON, July 20, 1881, 8.30 A. M. }

The progress of the President toward recovery continues uninterruptedly. He has passed a quiet night. Pulse this morning 86, temperature 98.4°, respiration 18.

7 P. M. The President has passed an excellent day. At 1 P. M. his pulse was 88, temperature 98.4°, respiration 18. At the present time his pulse is 98, temperature 99.6°, respiration 19.

TO THE CONSULTING SURGEONS.—7 P. M.

During the past twenty-four hours the President's progress has been uniformly satisfactory. He had a good night, and has expressed himself throughout the day as feeling quite comfortable. The medication reported in our last telegram has been continued without change. At 8.30 A. M., pulse 86, temperature 98.4°, respiration 18. At 1 P. M., pulse 88, temperature 98.4°, respiration 18. At 7 P. M., pulse 98, temperature 99.6°, respiration 19.

EXECUTIVE MANSION,
WASHINGTON, July 21, 1881, 8.30 A. M. }

The President has had a good night, and is doing excellently this morning. Pulse 88, temperature 98.4°, respiration 18.

7 P. M. The President has had another good day. At 1

p. m. his pulse was 92, temperature 98.4°, respiration 19. At 7 p. m., pulse 96, temperature 99.9°, respiration 19.

TO THE CONSULTING SURGEONS.—7 P. M.

Since our telegram of yesterday the President has continued to do well. He passed a comfortable night. This morning a morsel of clothing about one quarter of an inch square came away spontaneously with the pus from the deeper part of the wound. It proved on examination to consist chiefly of cotton fibres, with a few woollen fibres adhering. Medication continued without change. At 8.30 a. m. his pulse was 88, temperature 98.4°, respiration 18. At one p. m. pulse 92, temperature 98.4°, respiration 19. At 7 p. m., pulse 96, temperature 99.9°, respiration 19.

EXECUTIVE MANSION, }

WASHINGTON, July 22, 1881, 8.30 A. M. }

The President rested well during the night and is quite easy this morning. Pulse 88, temperature 98.4°, respiration 17.

7 P. M. The progress of the President's case continues without material change. At 1 p. m. his pulse was 98, temperature 98.4°, respiration 18. At 7 p. m., pulse 98, temperature 100.2°, respiration 19.

TO THE CONSULTING SURGEONS.—7 P. M.

The President slept well last night, and has been easy during the day. At the morning dressing, the wound, which is looking very well, discharged several ounces of healthy pus. A little solid fragment that floated out with the discharge proved to consist of a thin scale of bone, about one eighth of an inch in length, with a morsel of sloughing, fibrous tissue and a number of adhering fibres of cotton and wool. He continues to take and digest a reasonable quantity of nourishment. The evening hypodermic injection of sulphate of morphia (one eighth of a grain) and the quinia (three grains thrice daily) have also been continued. At 8 a. m. his pulse was 88, temperature 98.4°, respiration 17. At 1 p. m., pulse 98, temperature 98.4°, respiration 18. At 7 p. m., pulse 98, temperature 100.2°, respiration 18.

EXECUTIVE MANSION, }

WASHINGTON, D. C., July 23, 10 A. M. }

The President was more restless last night, but this morning at 7 A. M., while preparations were made to dress his wound his temperature was found to be normal. Pulse 92, temperature 98.4°, respiration 19. At 7.30 he had a slight rigor, in consequence of which the dressing of his wound was postponed; reaction followed promptly, and the dressing has now just been completed. At present his pulse is 110, temperature 101, respiration 24.

7 P. M. After the bulletin of 10 A. M. the President's fever continued. At 11.30 he again had a slight rigor and his temperature rose until at 12.30 o'clock it was 104°, pulse 125, respiration 26. Between that time and 1 p. m. perspiration made its appearance and the temperature of the patient began to fall gradually. It is now 101.7°, pulse 118, respiration 25. There has been a free discharge from the wound during the day.

WASHINGTON, D. C., July 23, 1881.

TO LOWELL, *London*: About noon to-day the President's condition became very suddenly worse. He had chills, alternating with fever, increased pulse, and very high temperature. His symptoms at 4.30 are better, and he is much easier in every respect. The consulting surgeons, Drs. Hamilton, of New York, and Agnew, of Philadelphia, have been summoned, and are now en route to Washington by special train. BLAINE, *Secretary*.

TO LOWELL, *Minister, London*: At 10 o'clock to-night the President's symptoms are better. Pulse, temperature, and respiration are improved. The distressing nausea has left and there is no appearance of chills. BLAINE, *Secretary*.

EXECUTIVE MANSION, }

WASHINGTON, July 24, 1881, 10 A. M. }

The President was more restless than usual during the night, and had another rigor just before midnight. This morning, at 8.15, his pulse was 98, temperature 98.4°, respiration 18. A consultation was then held with Dr. Hamilton, of New York, and Dr. Agnew, of Philadelphia, after which a counter-opening was made through the integument of the back, about three inches below the wound, which it is hoped will facilitate the drainage of pus and increase the chances of recovery. The President bore the operation well. His pulse is now 112.

4 P. M. The President has been much relieved by the operation of this morning, and the pus has been discharging satisfactorily through the opening. At noon to-day his pulse was 118, temperature 99.8°, respiration 24. At present his pulse is 104, temperature 99.2°, respiration 23.

WASHINGTON, D. C., July 24.

TO LOWELL, *Minister, London*: At midnight the President had another chill, and was restless and uncomfortable till near morning. At a consultation of all his physicians, at 8 o'clock, a surgical operation was resolved upon, and an incision made in his back, below the wound, to facilitate the drainage of pus. The result was very favorable, and at 12 o'clock noon, his condition is improved. The President endured the knife without ether, and without the slightest tremor. We are anxious and hopeful. BLAINE, *Secretary*.

TO LOWELL, *Minister, London*: At 6 o'clock, p. m., the President's symptoms continue favorable. The result of the surgical operation of this morning has proved beneficial.

BLAINE, *Secretary*.

TO LOWELL, *Minister, London*: At 11 o'clock p. m., the President's condition is improved. He has much less fever, and a general subsidence of unfavorable symptoms.

BLAINE, *Secretary*.

EXECUTIVE MANSION, }

WASHINGTON, D. C., July 25, 1881, 8.30 A. M. }

The President has passed a more comfortable night, and has had no rigor since that reported in the bulletin of yesterday morning. He is doing well this morning. Pulse 96, temperature 98.4°, respiration 18.

7 P. M. The President has done well during the day. His afternoon fever did not come on till after three o'clock. It is somewhat higher than yesterday, but there has been no chill. At noon his pulse was 104, temperature 98.4°, respiration 20. At 7 p. m. his pulse was 110, temperature 101.8°, respiration 24.

TO LOWELL, *Minister, London*: —

The President has passed a fairly comfortable day. Toward nightfall his pulse and temperature rose higher than was anticipated, and the flow of pus was not quite so free as desired. At 11 o'clock, p. m., his symptoms are more favorable, giving promise of general improvement to-morrow.

(Signed) BLAINE, *Secretary*.

EXECUTIVE MANSION, }

WASHINGTON, July 26, 1881, 8.30 A. M. }

The President was somewhat restless during the night, and the fever, which had subsided after our last bulletin, rose again about midnight, and continued till 3 A. M., after which it again subsided. He is now about as well as yesterday at the same hour. Pulse 102, temperature 98.4°, respiration 18.

7 P. M. The President has done well during the day. At the dressing of his wound after the morning bulletin was issued a displaced spiculum of the broken rib, about half an inch long, was removed. The track of the wound at this point was dilated, and a larger drainage tube inserted for the purpose of facilitating the discharge of pus. Since that time he has had several quiet naps. He has taken more nourishment than during any of the last five days, without gastric irritation, and when the wound was dressed this evening the discharge of healthy pus was satisfactorily abundant. At noon his pulse was 106, temperature 98.4°, respiration 19. At seven p. m. pulse 104, temperature 100.7°, respiration 22.

TO LOWELL, *Minister, London*: —

At 11 o'clock, p. m., the President's physicians report temperature and respiration normal, and pulse 96; best report at same hour for five nights. The entire day has been most encouraging, and a feeling of confidence is rapidly returning.

BLAINE, *Secretary*.

EXECUTIVE MANSION, }

WASHINGTON, July 27, 1881, 8 A. M. }

The President slept sweetly last night from about 8 p. m. to 5 A. M., with but a slight break of short duration at 11 p. m. Since 5 o'clock this morning he has dozed quietly, awakening at intervals. He takes his nourishment well, and his general condition is improving. He expresses himself as feeling better, and more rested. Pulse 94, temperature 98.4°, respiration 18.

12.30 P. M. The President's wound was dressed just after the morning bulletin was issued. It looks well, and the pus, which is healthy in character, is discharging freely. Since then he has rested quietly, and takes his nourishment readily and without gastric disturbance. At present his pulse is 90, temperature 98.4°, respiration 18.

7 P. M. The President is still resting quietly. He has been able to take more nourishment to-day than for several days past, and up to the present hour has had no febrile rise of tem-

perature. His wound has just been dressed. It looks well and has continued to discharge healthy pus in sufficient quantity during the day. His pulse is now 96, temperature 98.5°, respiration 20.

EXECUTIVE MANSION,
WASHINGTON, D. C., July 28, 1881, 8 A. M. }

The President rested well during the night, and no rigor or febrile disturbance has occurred since the bulletin of yesterday evening. This morning the improvement of his general condition is distinctly perceptible. He appears refreshed by the night's rest, and expresses himself cheerfully as to his condition. Pulse 92, temperature 98.4°, respiration 18.

12.30 P. M. The President bore the dressing of his wound this morning with less fatigue than hitherto. It appears well, and is discharging sufficiently. Shortly afterwards his bed was rolled into an adjoining room, while that occupied till now is being thoroughly cleansed and put in order. His pulse is now 94, temperature 98.5°, respiration 18.

7 P. M. The President has passed a pleasant day, and has taken his nourishment with apparent relish. His temperature continued normal until about 5 o'clock, when a moderate afternoon rise occurred, which, however, gives the patient but slight discomfort and causes no anxiety. At present his pulse is 104, temperature 100.5°, respiration 20.

TO LOWELL, Minister, London:—

This afternoon and evening the President has shown some increase in pulse and temperature, but not sufficient to create uneasiness on the part of his physicians. At 11 o'clock he is resting very quietly.

BLAINE, Secretary.

EXECUTIVE MANSION,
WASHINGTON, July 29, 1881, 8.30 A. M. }

Immediately after the evening dressing yesterday the President's afternoon fever began gradually to subside. He slept well during the night, and this morning is free from fever, looks well, and expresses himself cheerfully. No rigors have occurred during the past twenty-four hours, nor indeed at any time since the 25th instant. A moderate rise of temperature in the afternoon is to be anticipated for some days to come. At present his pulse is 92, temperature 98.4°, respiration 18.

12.30 P. M. The President bore the dressing of his wound well this morning, and exhibited very little fatigue after its completion. The appearance of the wound, the character and quantity of the discharge, and the general condition of the patient are satisfactory. He rests well, and takes an adequate quantity of nourishment. At present his pulse is 98, temperature 98.4°, respiration 19.

7 P. M. The President has been comfortable and cheerful during the day, and has had quite a nap since the noon bulletin was issued. The afternoon febrile rise came on later, and was not so marked as yesterday. The wound has been discharging freely and looks well. At present his pulse is 98, temperature 100°, respiration 20.

TO LOWELL, Minister, London:—

The President's afternoon fever was less to-day than yesterday, and at this hour, 11.30 P. M., has almost disappeared. Temperature very nearly normal. His wound is in a healthy condition, and he is doing well in all respects. His physicians are greatly encouraged.

BLAINE, Secretary.

EXECUTIVE MANSION,
WASHINGTON, D. C., July 30, 1881, 8.30 A. M. }

The President enjoyed a refreshing sleep during the greater part of the night. The slight febrile rise of yesterday afternoon had subsided by midnight, and this morning his temperature is again normal. A gradual improvement of his general condition in all particulars is observable, and is recognized by himself. His pulse is now 92, temperature 98.5°, respiration 18.

12.30 P. M. The President showed no fatigue from the dressing of his wound this morning. It looks very well, and the discharge of pus is satisfactory in quantity and quality. His general condition continues gradually to improve. A moderate quantity of solid food has been added to his nourishment, and was eaten with relish. A frame has been introduced beneath the mattress of his bed, by which his head and shoulders have been elevated somewhat, and he expresses himself as well pleased with the change of position. At present his pulse is 98, temperature 98.5°, respiration 20.

7 P. M. The President has passed the day comfortably, without febrile or unpleasant symptoms, and has taken an ample amount of nourishment. The afternoon rise of temperature is moderate, and did not commence till about 5 o'clock. The discharge of pus has been abundant, and at the evening dress-

ing was washed away freely from the deeper parts of the wound. At present his pulse is 104, temperature 100.2°, respiration 20.

TO LOWELL, Minister, London:—

The President continues to improve steadily and markedly. He is perhaps better to-day than at any other time since he was wounded.

BLAINE, Secretary.

EXECUTIVE MANSION,
WASHINGTON, D. C., July 31, 1881, 8.30 A. M. }

The President slept well during the night and awoke refreshed this morning. The afternoon fever subsided earlier than the night before, and had quite disappeared by 10 P. M. His appearance and expressions this morning indicate continued improvement. At present his pulse is 94, temperature 98.4°, respiration 18.

12.30 P. M. The President bore the morning dressing of his wound without fatigue. It continues to look well and discharge adequately. After the wound was dressed he ate with relish a breakfast of solid food, and has since passed a comfortable morning, during which he had a pleasant nap. The quantity of nourishment now taken daily is regarded as quite sufficient to support his system, and favor the gradual increase in strength which is plainly observable. At present his pulse is 100, temperature 98.5°, respiration 19.

7 P. M. The President has passed an excellent day. From just after the morning dressing till about 6 P. M., he has had his head and shoulders elevated by a frame beneath the mattress; he has taken and relished an ample supply of nourishment, and continues to improve in general condition. The appearance of the wound at the evening dressing was in every way satisfactory. The afternoon rise of temperature has been quite insignificant. At present his pulse is 104, temperature 99°, respiration 20.

WASHINGTON, D. C., July 31, 11.30 P. M.

TO LOWELL, Minister, London:—

The President is steadily improving, and I shall henceforth omit my daily telegram. Not hearing from me, you may infer that all goes well.

BLAINE, Secretary.

EXECUTIVE MANSION,
WASHINGTON, D. C., August 1, 1881, 8.30 A. M. }

The President slept well during the night, and this morning is cheerful and expresses himself as feeling better than at any time since he was hurt. After the slight rise of yesterday afternoon, his temperature became again normal early in the evening and so continues. He appears stronger, and has evidently made good progress on the road towards recovery during the last few days. His pulse is now 94, temperature 98.4°, respiration 18.

12.30 P. M. The President's wound continues to do well; at the morning dressing it was found to be in all respects in a satisfactory condition. After the dressing was concluded, his head and shoulders were raised in the same manner as yesterday, and he took solid food for breakfast with more relish than he has hitherto shown. At present his pulse is 100, temperature 98.4°, respiration 19.

7 P. M. The President remained with his head and shoulders elevated until time for dressing his wound this evening. The wound continues to progress in a satisfactory manner, and discharges healthy pus freely from the deeper as well as the superficial portions. He has taken nourishment well and in sufficient quantity, and in all respects continues to do well. The rise of temperature this afternoon is slight. At present his pulse is 104, temperature 99.5°, respiration 20.

EXECUTIVE MANSION,
WASHINGTON, August 2, 1881, 8.30 A. M. }

The President passed a very pleasant night and slept sweetly the greater part of the time. This morning he awoke refreshed and appears comfortable and cheerful. Pulse 94, temperature 98.4°, respiration 18.

12.30 P. M. The President is passing the day comfortably with his head and shoulders raised in the same manner as yesterday. At the morning dressing his wound was found to be doing admirably. His pulse is now 99, temperature 98.4°, respiration 19.

7 P. M. The President has continued to progress favorably during the day, and appears perceptibly better in his general condition than yesterday, a more natural tone of voice being especially perceptible. The appearance of the external wound at the evening dressing was exceedingly good. That made by the ball is rapidly granulating, while the discharge from the deeper portion of the wound, which is abundant and healthy,

comes through the counter-opening made by the operation. The rise of temperature this afternoon is moderate and attended by no inconvenience to the patient. At present his pulse is 104, temperature 100°, respiration 20.

EXECUTIVE MANSION, }
WASHINGTON, August 3, 1881, 8.30 A. M. }

¶ The President slept tranquilly the greater part of the night. This morning his temperature is normal and his general condition satisfactory. Another day of favorable progress is anticipated. At present his pulse is 96, temperature 98.4°, respiration 18.

12.30 P. M. The President continues to progress steadily toward convalescence. He has taken to-day an increased proportion of solid food, his wound is doing well, and his general condition is better than yesterday. At present his pulse is 100, temperature 98.4°, respiration 19.

7 P. M. The President has passed a very satisfactory day. The wound continues to do well. He takes an adequate quantity of nourishment and appears in all respects better than at any time since he was injured. The rise of temperature this afternoon is slight. At present his pulse is 102, temperature 99.4°, respiration 19.

EXECUTIVE MANSION, }
WASHINGTON, D. C., August 4, 1881, 8.30 A. M. }

The President continues to improve. He slept well during the night, and this morning looks and expresses himself cheerfully. Another satisfactory day is anticipated. At present his pulse is 90, temperature 98.4°, respiration 18. The next bulletin will be issued this evening, and hereafter the noon bulletin will be dispensed with.

7 P. M. As the morning bulletin indicated would probably be the case, the President has passed another good day, without drawback or unpleasant symptom of any kind. He has taken his nourishment well, and shown little fatigue after his dressings and changes of position. The wound is doing well both in appearance and in the character and amount of the discharge. At 12.30 P. M. his pulse was 96, temperature 98.4°, respiration 18. The afternoon rise of temperature came on late, and was moderate in degree. At 7 P. M. his pulse is 102, temperature 102.2°, respiration 19.

EXECUTIVE MANSION, }
WASHINGTON, D. C., August 5, 1881, 8.30 A. M. }

The President slept naturally the greater part of the night, although he has taken no morphia during the last twenty-four hours. His improved condition warranted, several days ago, a diminution in the quantity of morphia administered hypodermically at bedtime, and it was reduced at first to one twelfth and afterwards to one sixteenth of a grain in the twenty-four hours without any consequent unpleasant result, and finally has been altogether dispensed with. His condition this morning exhibits continued improvement, and another good day is anticipated. At present his pulse is 88, temperature 98.4°, respiration 18.

7 P. M. The President has passed another good day. The appearance of the wound and the character and amount of the discharge of pus continue satisfactory. He has taken an adequate quantity of nourishment, and has had several pleasant naps during the day. At 12.30 P. M. his pulse was 99, temperature 98.4°. After 4 P. M. his temperature began to rise as usual, but to a moderate degree and without perceptible dryness of skin. At present his pulse is 102, temperature 100.4°, respiration 19.

EXECUTIVE MANSION, }
WASHINGTON, D. C., August 6, 1881, 7 P. M. }

The President passed a comfortable morning, his symptoms and general condition being quite satisfactory. At 12.30 P. M. his pulse was 100, temperature 99.9°, respiration 19. During the afternoon he complained somewhat of the weather, the extreme heat being such that it was found impracticable to keep the temperature of his room much below 90 without closing the windows and doors, which was not thought prudent. The afternoon rise of temperature began as late as yesterday, but has been higher, though unaccompanied by dryness of skin. At 7 P. M. his pulse was 102, temperature 101.8°, respiration 19. The appearance of the wound at the evening dressing was, however, good, and there has been no interruption to the flow of pus.

EXECUTIVE MANSION, }
WASHINGTON, August 7, 1881, 8.30 A. M. }

Shortly after the bulletin of last evening was issued the President fell into a pleasant sleep, during which the febrile rise subsided and was no longer perceptible when he awoke at 10 P. M. Subsequently he slept well, though with occasional

breaks, during the rest of the night. No morphia or other anodyne was administered. This morning he is in good condition, although the effects of the febrile disturbance of yesterday are still slightly perceptible in pulse and temperature. At present his pulse is 96, temperature 98.7°, respiration 18.

7 P. M. The President has been comfortable during the day, although his temperature began to rise earlier than yesterday and rose almost as high. At 12.30 P. M. his pulse was 104, temperature 100°, respiration 20. At 7 P. M. his pulse was 104, temperature 101.2, respiration 20. Nevertheless, he has been able to take nourishment as usual, and has had several refreshing naps during the day. The discharge of pus has been liberal and healthy in character.

EXECUTIVE MANSION, }
WASHINGTON, August 8, 1881, 8.30 A. M. }

The President passed a comfortable night and slept well without anodyne. The rise of temperature of yesterday afternoon subsided during the evening, and did not recur at any time through the night. At present he appears better than yesterday morning. Pulse 94°, temperature 98.4, respiration 18.

10.30 A. M. It having become necessary to make a further opening to facilitate the escape of pus, we took advantage of the improved condition of the President this morning. Shortly after the morning bulletin was issued he was etherized. The incision extended downward and forward, and a counter-opening was made into the track of the ball below the margin of the twelfth rib, which it is believed will effect the desired object. He bore the operation well, has now recovered from the effects of the etherization and is in excellent condition.

7 P. M. After the last bulletin was issued, the President suffered somewhat for a time from nausea due to the ether, but it has now subsided. He has had several refreshing naps, and his general condition is even better than might have been expected after the etherization and operation. At noon his pulse was 104°, temperature 100.2, respiration 20. At present his pulse is 108°, temperature 101.9, respiration 19. Under the circumstances the fever must be regarded as moderate.

TO LOWELL, Minister, London:—

The President's condition at 11 o'clock to-night is considered by his physicians as encouraging. The increase of pulse and temperature is regarded as a natural result of the radical operation of this morning, in which a deep incision, three inches in length on the surface, was made. The same cause may possibly produce a still higher pulse and temperature to-morrow, after which a decided amelioration is confidently anticipated by the surgeons.

BLAINE, Secretary.

EXECUTIVE MANSION, }
WASHINGTON, D. C., August 9, 1881, 8.30 A. M. }

Notwithstanding the effect of yesterday's operation the President slept the greater part of the night without the use of anodyne. The febrile rise of yesterday afternoon slowly subsided during the night. This morning at 8.30 his pulse is 98, temperature 99.8°, respiration 19. Since yesterday afternoon small quantities of liquid nourishment, given at short intervals, have been retained, and this morning large quantities are being administered without gastric disturbance.

12.30 P. M. At the dressing of the President's wound this morning it was found that pus had been discharging spontaneously and freely through the counter-opening made yesterday. He has been quite comfortable this morning, and has taken a liberal supply of liquid nourishment. His pulse is now 104, temperature 99.7°, respiration 19.

7 P. M. The President has been very easy during the day, and has continued to take the nourishment allowed without gastric disturbance. The discharge of pus from his wound is quite abundant, and it is evident that thorough drainage has been secured by yesterday's operation. The degree of fever this afternoon differs little from that of yesterday. Pulse 106, temperature 101.9°, respiration 19.

WASHINGTON, D. C., August 9, 1881.

TO LOWELL, Minister, London:—

At 11 o'clock to-night the physicians report the President's condition as satisfactory. He sleeps well without the aid of anodynes. It is now the sixth day since he took any morphia. The pulse and temperature did not rise so high from the effect of yesterday's operation as the surgeons expected. The situation is one of continuing anxiety, but also of cheerful hope.

BLAINE, Secretary.

EXECUTIVE MANSION, }
WASHINGTON, August 10, 1881, 8 A. M. }

The President slept soundly during the night, and this morning his temperature is again normal, although his pulse is still

frequent. At present it is 104, temperature 98.5°, respiration 19.

12.30 p. m. The President is getting through the day in a very satisfactory manner. He has asked for and taken a small quantity of solid food, in addition to the liquid nourishment allowed. At the morning dressing the discharge of pus through the new opening was more free than at any previous time; its character was good and the wound looks well. Temperature and respiration continue within the normal range, although the debility following the operation is still shown by the frequency of the pulse. At present his pulse is 110, temperature 96.6°, respiration 19.

7 p. m. The President has passed an excellent day. The drainage of the wound is now efficient and the pus secreted by its deeper portions has been coming away spontaneously. The afternoon rise of temperature is almost a degree less than yesterday and the day before. Pulse at present 108, temperature 101°, respiration 19.

To LOWELL, Minister, London:—

At 1 o'clock p. m. the President's condition has not essentially changed since the morning report. At noon he signed an important public document, to which his signature was indispensable, with a firm, clear hand.

BLAINE, Secretary.

To LOWELL, Minister, London:—

The President is progressing satisfactorily. He is now (10 p. m.) in a refreshing sleep. His temperature has fallen nearly one degree since yesterday. The drainage of the wound to-day has been efficient and spontaneous, and he has taken more nourishment than any day for five days.

HITT, Assistant Secretary.

EXECUTIVE MANSION, {

WASHINGTON, D. C., August 11, 1881, 8.30 A. M. {

The President has passed an exceedingly good night, sleeping sweetly, with but few short breaks, and awakening refreshed this morning at a later hour than usual. At the morning dressing, just completed, it was found that the deeper parts of the wound had been emptied spontaneously. The quantity of pus secreted is beginning to diminish. Its character and the appearance of the wound are healthy. His temperature shows an entire absence of fever this morning, and his pulse, which is less frequent than yesterday, is improving in quality. At present it is 100, temperature 98.6°, respiration 19.

12.30 p. m. The President is doing well to-day. Besides a liberal supply of liquid nourishment at regular intervals, he has taken for breakfast, with evident relish, an increased quantity of solid food. He continues free from fever. His skin is moist, but without undue perspiration; pulse 102, temperature 98.6°, respiration 19.

7 p. m. After the noon bulletin was issued the President's condition continued as then reported until about 4 p. m., when the commencement of the afternoon febrile was noted. In its degree it did not differ materially from that of yesterday. His pulse is now 108, temperature 101.2°, respiration 19.

EXECUTIVE MANSION, {

WASHINGTON, D. C., August 12, 1881, 8.30 A. M. {

The President slept well during the greater part of the night. The fever of yesterday afternoon subsided during the evening, and has not been perceptible since 10 p. m. His general condition this morning is good. Pulse 100, temperature 98.6°, respiration 19.

12.30 p. m. The President has passed a comfortable morning. He continues to take, with repugnance, the liquid nourishment allowed, and ate with relish for breakfast a larger quantity of solid food than he took yesterday. At present his pulse is 100, temperature 99.3°, respiration 19.

7 p. m. The President has passed a comfortable day. At the morning dressing the wound was found to be doing well. The quantity of pus secreted is gradually diminishing. Its character is healthy. The rise of temperature this afternoon was about the same point as yesterday. At present the pulse is 108, temperature 101.2°, respiration 19.

Lowell, Minister, London:—

The President is doing well, pus diminishing and healthy. At present rise of temperature same as yesterday. Appetite improving.

HITT, Acting Secretary.

At 11 A. M. of August 18, 1881, a communication was received from the President's physician, Dr. J. C. Warren, which professes to present my views in regard to the treatment of the President's wound. As this article has been given the basis for an editorial on the same

subject in *The New York Herald*, and has, as I understand, been the subject of comment in other papers, I deem it my duty to say that in no particular do the details given represent my views of the case; nor were they ever given by me to any representative of the press.

D. HAYES AGNEW.

EXECUTIVE MANSION, {

WASHINGTON, D. C., August 13, 1881. {

The President did not sleep as well as usual during the early part of the night. After midnight, however, his sleep was refreshing, and only broken at long intervals. This morning he has a little fever, nevertheless he expresses himself as feeling better than for several days. Pulse 104.5, temperature 100.8°, respiration 19.

1.30 p. m. The President has been cheerful and easy during the morning, and his temperature has fallen a little more than a degree and a half since the morning bulletin was issued. The wound is discharging healthy pus. His pulse is now 102, temperature 99.2°, respiration 18.

7.30 p. m. Since the last bulletin the President has continued to do well. The afternoon fever has been half a degree lower than yesterday. At the evening dressing the appearance of the wound was improved. The discharge of pus has been adequate, and its character is healthy. At present his pulse is 104, temperature 100.7°, and respiration 19.

EXECUTIVE MANSION, {

WASHINGTON, D. C., August 14, 1881, 8.30 A. M. {

The President slept well during the night, and this morning expressed himself as feeling comfortable. His temperature is one degree less than at the same hour yesterday. His general condition is good. Pulse 100, temperature 99.8°, respiration 18.

12.30 p. m. The President has done well this morning. His temperature has fallen one half of a degree since the last bulletin was issued. At the morning dressing the condition of the wound was found to be excellent, and the discharge of pus adequate and healthy. Pulse 96, temperature 99.3°, respiration 18.

6.30 p. m. The condition of the President has not materially changed since noon. The afternoon febrile rise is about the same as yesterday. Pulse 108, temperature 100.8°, respiration 19.

EXECUTIVE MANSION, {

WASHINGTON, D. C., August 15, 1881, 8.30 A. M. {

The President did not sleep as well as usual last night until towards 3 o'clock. His sleep was not sound, and he awoke at short intervals. His stomach was irritable, and he vomited several times. About 3 o'clock he became composed, and slept well until after 7 this morning. His stomach is still irritable, and his temperature reached higher than yesterday. At present his pulse is 108, temperature 100.2°, respiration 20.

12.30 p. m. Since the last bulletin the President has not again vomited, and has been able to retain the nourishment administered. At the morning dressing the discharge of pus was free and of good character. Since then his pulse has been more frequent, but the temperature has fallen to a little below what it was at this time yesterday. At present his pulse is 118, temperature 99°, respiration 19.

6.30 p. m. The irritability of the President's stomach returned during the afternoon, and he has vomited three times since 1 o'clock. Although the afternoon rise of temperature is less than it has been for several days, the pulse and respiration are more frequent, so that his condition is on the whole less satisfactory. His pulse is now 130, temperature 99.6°, respiration 22.

To LOWELL, Minister, London:—

The President's condition is less satisfactory. Inability of the stomach has returned, the patient vomiting three times since 1 o'clock. Temperature 99.6°, less for several days; pulse 130, respiration 22.

HITT, Acting Secretary.

EXECUTIVE MANSION, {

WASHINGTON, D. C., August 16, 1881, 8.30 A. M. {

The President was somewhat restless and vomited several times during the early part of the night. Since 3 o'clock this morning he has not vomited and has slept tranquilly most of the time. Nutritious enemata are successfully employed to sustain him. Altogether the symptoms appear less urgent than yesterday afternoon. At present his pulse is 110, temperature 98.6°, respiration 18.

12.30 p. m. The President has been tranquil and has not vomited since the morning bulletin, but has not yet rallied from the prostration of yesterday afternoon as much as was hoped. The enemata administered are, however, still retained. At present his pulse is 114, temperature 98.3°, respiration 18.

7 p. m. The President's symptoms are still grave, yet he seems to have lost no ground during the day, and his condition on the whole is rather better than yesterday. He has vomited but once during the afternoon. The enemata are retained. At present his pulse is 120, temperature 98.9°, respiration 19.

EXECUTIVE MANSION, }
WASHINGTON, D. C., August 17, 1881, 8.30 a. m. }

The President has passed a tranquil night, sleeping most of the time. He continues to retain the nutritive enemata, and has not vomited since the last bulletin. His general condition appears more hopeful than this time yesterday. Pulse 110, temperature 98.3°, respiration 18.

6.30 p. m. The President's condition is even better than it was this morning. There has been no vomiting during the day, and the enemata continue to be retained; moreover, a teaspoonful of beef extract has been twice administered by the mouth and not rejected, and small quantities of water swallowed from time to time excite no nausea. The wound continues to do well. At present his pulse is 112, temperature 98.8°, respiration 18.

EXECUTIVE MANSION, }
WASHINGTON, D. C., August 18, 1881, 8.30 a. m. }

The President has passed a very comfortable night, sleeping well the greater part of the time. There has been no further vomiting, and the nutritive enemata are still retained. This morning his pulse is slower, and his general condition better than yesterday at the same hour. Pulse 104, temperature 98.8°, respiration 17.

12.30 p. m. The President is suffering some discomfort this morning from commencing inflammation of the right parotid gland. In other respects his condition is somewhat improved, and especially his stomach is becoming less intolerant. He has asked for and retained several portions of liquid nourishment, much more than he could swallow yesterday. The nutritive enemata continue to be used with success. At present his pulse is 108, temperature 98.4°, respiration 18.

6.30 p. m. The President has done well during the day. He has taken additional nourishment by the mouth this afternoon, with evident relish and without subsequent nausea. There is some rise of temperature, but his general condition is rather better than at this time yesterday. Pulse 108, temperature 100°, respiration 18.

To LOWELL, Minister, London:—

At 2 o'clock p. m. the President shows a slight improvement in his power to retain and digest food, but his general condition is not strongly re-assuring.

BLAINE, Secretary.

To LOWELL, Minister, London:—

The condition of the President at 11 o'clock to-night shows improvement. He has swallowed, retained, and apparently digested nine ounces of liquid food during the day, asking for it himself and relishing it. The swelling of the parotid gland has created some uneasiness in the public mind, though it is not regarded as especially discouraging by his medical advisers.

BLAINE, Secretary.

EXECUTIVE MANSION, }
WASHINGTON, D. C., August 19, 1881, 8.30 a. m. }

The President slept much of the night, and this morning is more comfortable than yesterday. The swelling of the right parotid gland has not increased since yesterday afternoon, and is now free from pain. Nutritive enemata are still given with success, and liquid food has already this morning been swallowed and relished. Pulse 100, temperature 98.4°, respiration 17.

12.30 p. m. The President's condition has perceptibly improved during the last twenty-four hours. The parotid swelling is evidently diminishing, and it has not pained him since last night. He is taking to-day an increased quantity of liquid food by the mouth, which is relished, and produces no gastric irritation. Pulse is now 106, temperature 98.8°, respiration 17.

6.30 p. m. The President has been easy during the afternoon, and the favorable conditions reported in the last bulletin continue. The swollen parotid gland has not been painful. The temperature is the same, the pulse rather less frequent than at this hour yesterday. Pulse 106, temperature 100, respiration 18.

To LOWELL, Minister, London:—

In the judgment of his physicians the President has gained since the last reports. He has taken during the day twenty-two

ounces of liquid food with relish and without apparent tendency to nausea or indigestion. Other symptoms not essentially changed. Pulse and temperature possibly a little better. The swelling of the parotid gland has not increased, and fear of its suppuration has somewhat diminished. At this hour (11 p. m.) the President is sleeping quietly.

BLAINE, Secretary.

EXECUTIVE MANSION, }
WASHINGTON, D. C., August 20, 1881, 8.30 a. m. }

The President has passed a quiet night, and this morning his condition does not differ materially from what it was yesterday at the same hour. The swelling of the parotid gland is unchanged and is free from pain. This morning his pulse is 98, temperature 98.4°, respiration 13.

12.30 p. m. The President continues to do well. He is taking liquid food by the mouth in increased quantity and with relish. The nutritive enemata are still successfully given, but at longer intervals. His pulse is now 107, temperature 98.4°, respiration 18. At the morning dressing the wound was looking well and the pus discharged was of a healthy character. After the operation of August 8, the flexible tube used to wash out the wound at each dressing readily followed the track of the ball to the depth of three and a half or four inches. At the dressings, however, a small quantity of healthy pus came, as was believed, from the part of the track beyond this point, either spontaneously, or after gentle pressure over the anterior surface of the right iliac region; but this deeper part of the track was not reached by the tube until yesterday morning, when the separation of a small slough permitted it to pass unresisted downward and forward for the distance of twelve and a half inches from the external surface of the last incision. This facilitates the drainage and cleansing of the deeper parts of the wound, but has not been followed by any increase in the quantity of pus discharged. The large pus cavity which has formed in the immediate vicinity of the broken rib, is filling up with healthy granulations, and the original wound of entrance as far as that cavity has healed.

6.30 p. m. The President has passed the day quietly. He has been able to take more liquid food by the mouth than yesterday, and the quantity given by enema has been proportionably diminished. The parotid swelling remains about the same. Pulse 110, temperature 100.4°, respiration 19.

To LOWELL, Minister, London:—

The President has passed a fairly comfortable day. His condition has not materially changed since last night. Pulse and temperature both a little higher, possibly attributable to the heat of which he has complained. He has shown increased appetite, and has swallowed during the day thirty-three ounces of liquid food, principally milk or its preparations. At 11 o'clock he is soundly asleep, with the fever of the afternoon slightly subsiding.

BLAINE, Secretary.

EXECUTIVE MANSION, }
WASHINGTON, D. C., August 21, 8.30 a. m. }

The President awoke more frequently than usual, yet slept sufficiently during the night and appears comfortable this morning. The parotid swelling is about the same but is not painful. He took liquid nourishment by the mouth several times during the night as well as this morning. Pulse 106, temperature 98.8°, respiration 18.

12.30 p. m. The President's condition continues about as at the morning bulletin, except that there is a slight rise of temperature. He continues to take liquid nourishment by the mouth as well as by enema. Pulse 108, temperature 99.4°, respiration 18.

6.30 p. m. The President has vomited three times during the afternoon; the administration of food by the mouth has, therefore, again been temporarily suspended and the nutritive enemata will be given more frequently. His temperature is lower, and his pulse rather less frequent than yesterday afternoon. The parotid swelling is painless, but stationary. Pulse 108, temperature 99.2°, respiration 18.

To LOWELL, Minister, London:—

The President's sleep last night was broken and restless. His symptoms throughout the day have been less favorable, and his general condition is not encouraging. He is unable to retain food on his stomach, having vomited twice during the afternoon, the last time at 5 o'clock. This evening he has been able to drink water and retain it. The swelling of the parotid gland has not increased. Pulse and temperature about the same as yesterday. His sleep up to this hour (11 p. m.) has been somewhat disturbed. We are all deeply anxious.

BLAINE, Secretary.

(To be concluded, with chart appended.)

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 22, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5 00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

THE PRESIDENT'S WOUND, AND THE MANAGEMENT OF THE CASE.

In discussing the President's wound as long ago as the fourteenth of July, that is, twelve days after the infliction of the injury, the JOURNAL gave expression to opinions which, even with the light now thrown on the case by the autopsy, it is not amiss to repeat. In an editorial of the above date we said:—

"The intercostal space through which the bullet forced its way is far too narrow to permit so large a projectile to pass without meeting with resistance from the ribs, which, as has been stated, were splintered by the ball. When we take into account the ease with which a ball is deflected from its path, there being, in fact, nothing so insignificant that may not influence its course, it is evident that in the present case it might easily have been turned to the right or left. In the latter direction the least possible deviation from its course would have brought it in contact with a large bony prominence, in the spongy tissue of which it would find a comparatively safe and firm lodging-place, the body of one of the dorsal vertebrae. A cross section of the abdomen at this point will show this bone to be the anatomical centre of the body, and amply protected in the direction from which the shot was fired by dense masses of muscles, tendons, and bone. Although the range was extremely close, the charge of powder was a light one, and might easily have exhausted itself upon such obstacles. This would leave the offending body in close contact with the nerve centres, and it is precisely to injury of such structures that one of the most prominent symptoms points, namely, the pain in the feet. Dr. Bliss is stated to have explained this symptom as produced by an injury of one of the sympathetic ganglia which lies directly in the track we have suggested. Had the ball been deflected to the right it would hardly have spent its force until it had penetrated deeply into the abdominal cavity. The theory that it has passed downwards into the pelvis and is in contact with the ischiatic plexus, is of course among the possibilities, for there is no track of which a bullet is not capable.

"The fact we have at our command up to the time of writing, we may safely say, give no symptoms of a penetrating wound of the abdominal cavity.

"If this be the case, the dangers of the future arise chiefly from the character of the wound itself rather than from the presence of the bullet, which thus far has not shown that it is not securely imbedded in a

place of comparative safety. The tortuous shape of gunshot wounds and their contused surfaces are often to blame for difficulties which it is common to ascribe to the missile. By good drainage and antiseptic treatment these may be happily surmounted.

"We have nothing but praise for the judicious manner in which the illustrious patient has been treated, and commend strongly the good judgment which refrained from making a meddlesome hunt after the ball."

The report of the autopsy, to be found in another column with the collected official bulletins issued by the attending surgeons during the progress of the case, shows that the ball, after splintering the ribs, was deflected to the left, as we suggested might be its course, and after fracturing the body of the first lumbar vertebra became firmly and safely encysted behind and not far from the pancreas. The future dangers, and the final fatal termination arose, as we predicted, from the character of the wound itself, its tortuous shape and contused surfaces, complicated by spiculae of fractured bones, and not from the presence of the bullet. Moreover, though the ball was not completely arrested by the body of the vertebra, its force was so much spent as to prevent any opening into the abdominal cavity.

We very much doubt how far any good end is to be subserved by much criticism of the management of the case, or by trying to guess what might have happened had this or that course been adopted. It is plain, and is generally acknowledged, that no good and much harm would have resulted from any serious attempt to extract the ball, even had it been possible to determine its real situation. But as we have before remarked, the freaks of bullets after once entering the body are infinite, and this the surgical history of our civil war abundantly illustrates. It was unfortunate, though very natural, that the attending surgeons were deceived as to the direction of the ball by the sinus created by the gravitating discharges, and we were disposed to imagine at the time when Drs. Agnew and Hamilton were suddenly summoned to Washington, July 24th, after the President's first chill, and again August 8th, when the patient was etherized, counter-openings being made lower than the original wound and drainage tubes inserted,—we supposed at these times, and especially at the second date, that a more extended, though fruitless, search was made for the ball than the public was aware of.

Whether, if the nature of the wound had been recognized at the outset and drainage tubes and all antiseptic devices had been freely and persistently employed, it would have been possible to prevent the accumulation and burrowing of the discharges, to keep the course of the wound aseptic, and conduct the case to a different termination is a speculation of a purely abstract character, which must be premised by the great difficulty of recognizing the course of the wound, and which as an abstract question, in view of the fact that scarcely any two gunshot wounds are alike, it is idle to discuss.

We have collated the official bulletins, those of Mr. Blaine to Mr. Lowell, and the report of the autopsy, that our readers might have them in one

place for convenient reference and as showing to some extent the progress of the case. Drs. Hamilton and Bliss, we understand, will shortly publish full accounts of the case drawn from their own notes, but we doubt whether any further material contributions to its history are likely to be made.

In justice to, though not in justification of, Dr. Bliss, whose name was intimately associated with the most regrettable incident, from a professional standpoint, in the course of the case, we reproduce elsewhere a statement lately made by him in the columns of a daily paper, in which he describes the manner of his being originally summoned to President Garfield and of his being retained in charge of the case.

We also reprint Dr. Hamilton's reported account of the autopsy.

There is one other point which may properly be remarked upon in the management of this case, though we do not call attention to it in any critical spirit. The absence of trained and experienced nurses from the patient's bedside has unquestionably excited comment upon the part of many physicians who would ordinarily wish to avail themselves of such for carrying out their instructions in cases of this delicate character. The results of the training schools for nurses have impressed the profession in our large cities more than ever with the many advantages trained and experienced nurses offer in the care of the sick, advantages never more apparent than when contrasted with the services of amateur attendants, however devoted.

THE TRIAL OF THE ASSASSIN.

THE body of our murdered President having been borne to its last resting-place, through the sorrowing throngs and amid the mourning emblems of a nation, and laid in the quiet grave overlooking the waters of one of our great Western lakes, there remains to the country the performance of the last duty directly entailed by the crime of the 2d of July,—the trial of the assassin.

Through all the trying emotions and exciting events which have rapidly succeeded each other since that fatal day the dignity and quiet self-respect manifested by this nation must be a surprise even to itself, and certainly to those unacquainted with the inherent strength of a free government. We hope and believe that this same attitude will be maintained even to the end.

There was a moment at first when horror and a longing for revenge struggled for the mastery in men's minds, but this was only for a moment; the nation quickly recovered its self-possession, and schooled itself to regard all the circumstances of the almost unprecedented blow which had fallen with the law-respecting control befitting the dignity of a great and free people.

We repeat, we hope and believe that this same characteristic will be preserved throughout the trial of the wretched creature, the immediate source of the nation's sorrow, to its termination in judgment and the execution of the sentence, whatever that may be.

Before the termination of that trial it would be as little fitting in us to say that the murderer should not be hanged or shot as to say, as has been said in high quarters, that shooting or hanging would be too good for him; but we know that competent authorities maintain that there are circumstances in his case which make it extremely probable that he is suffering from one of the forms of mental disease most destructive of responsible action; there are indications that his sufferings have been great enough to demand attention, if not sympathy, if, as we more than suspect, his deed arose partly from pure weakness of mind, and partly from a controlling delusion. At all events, he should not be condemned in advance, and is fairly entitled, under the laws, to an even-minded decision of his case.

Whether Guiteau is insane or not, we consider it our solemn duty to warn the public and the daily press that the very symptoms characteristic of insanity be not perverted into evidences of responsibility. The officers of our government, the public, and the press should calmly await the action of the courts, and at least not so excite a popular spirit of vindictiveness as to make a fair trial impossible and our justice a by-word in the future.

In expressing these opinions we are guided by no maudlin feelings of philanthropic sentimentality, and are fully impressed with the obligations and necessities imposed upon society for self-protection in the future against the repetition of crime, which, and not revenge, should be the end of all justice. As a mere question of policy, however, neither history nor sociology have taught us that a short shrift at a rope's end is the most effective restraint upon the class of mental monstrosity which, to us, Guiteau represents. We may wish that he and others like him had never been born, that their names might never find a place on men's tongues, that they might be foiled of the notoriety which they so often crave; but such wishes are not furthered by the taking of their lives on the wheel, on the rack, or on the scaffold.

WILLIAM WARREN GREENE.

WILLIAM WARREN GREENE was born in North Waterford, Oxford County, Maine, on the 1st of March, 1831. His father was Jacob Holt Greene, a man of rugged physical and intellectual build, an independent thinker, with marked inventive talent and a keen sense of justice, which made him an outspoken antislavery man at a period when it required courage to advocate views which are now universally entertained. His mother was Sarah Walker Frye, a descendant of the family which gave its name to the town of Fryeburg. When he was nine years old, he was placed under the instruction of his relative, the late Rev. Dr. William Warren, for whom he was named. At sixteen, he began to teach, and for several winters had charge of district schools in Bethel and in his native town, where he opened the first high school that Waterford ever had. From 1848 to 1851 he was a student in Bethel Academy. His medical studies were prosecuted under the preceptorship of the late Dr. Seth C. Hunkin.

and he attended lectures at the Berkshire Medical College, Pittsfield, Mass., in the medical department of the University of Michigan, graduating with great credit from the latter institution in 1855. A year or two after this, he was offered the demonstratorship of anatomy by his Alma Mater; but, being dependent upon his professional work for his income, he was obliged to decline the position, which brought no pay but honor. Immediately after graduating, he began practice in his old home, but removed to the town of Gray after two and a half years. In the fall of 1862, he served two months as volunteer surgeon in the Federal army. His old teachers in the Berkshire College, — some of them also his instructors in Ann Arbor — had kept track of the promising student; and, a vacancy occurring in the chair of theory and practice of medicine, the place was tendered him. He at once accepted, and removed to Pittsfield in November, 1862; but he was soon transferred to the chair of surgery, for which his natural endowments and cherished tastes peculiarly fitted him, and this position he filled until the close of his connection with the institution in 1868. In the autumn of 1865, the professorship of surgery in the Medical School of Maine was made vacant by the death of Dr. D. S. Conant, and Dr. Greene was called to it, giving his first course here in 1866. Excepting two years, in which ill health necessitated the appointment of temporary substitutes, he has given every surgical course in this school since that time. In the winter of 1867-68, he was professor of surgery in the University of Michigan, but resigned when the well-known homoeopathic difficulty arose. In 1868, he removed from Pittsfield to Portland. Already an active member of the Maine Medical Association, of the Massachusetts Medical Society, and of various other medical organizations, in 1870 he received the marked distinction of an election to honorary membership in the Medical Society of the State of New York. From 1872 to 1874 he was professor of surgery in the Long Island College Hospital, Brooklyn, N. Y., in this, as in every other school with which he was connected, winning easy recognition as a clear, forcible, and charming lecturer, and a clinical teacher of exceptional power. In 1880, he was elected president of the Maine Medical Association, and made his service memorable by his successful efforts to secure the passage of an anatomical bill by the State legislature. His inaugural address, recently published in the *JOURNAL*, was probably his most scholarly production.

Dr. Greene was twice married: in 1855, to Miss Lizzie Carleton, of Watertown, who died in 1860 without living issue; and in 1861, to Miss Lizzie A. Lawrence, of Fownd, who died in 1876. Two children survive him, a son of nineteen and a daughter of ten years of age. He had three brothers, all younger than himself: Jacob Lyman, president of the Connecticut Life Insurance Company; George Frye, who resides on the old homestead; and Samuel Thomas, who is a teacher in Belleville, Ontario. He had one sister, who died in 1878.

In July of this year he went to England to attend the meetings of the International Medical Congress. On the passage, however, on the steamer *Parthia*, he was suddenly attacked with complete suppression of urine, and died in a uræmic convulsion, after an illness of hardly twenty-four hours. The facilities on board the vessel were not such as to permit the preservation of the body until it could be brought to land, and the

burial took place on the 10th of August, the day of his death.

For many years Dr. Greene's work, both as practitioner and teacher, was almost exclusively in the department of surgery, and in this branch of medicine he had the leading practice in Eastern New England. He was unquestionably a genius. Few men possess his diagnostic skill, fewer still his marvelous facility with the knife; indeed, as an operator, it is difficult to conceive of his superior. His knowledge of anatomy was so accurate, and his grace, steadiness, and rapidity so striking, as to make the most difficult operation appear simple and easy. His daring was equal to his dexterity, and, while yet a young man in the profession, he performed the bold operation which, more than anything else, will hand his name down to posterity. This was the successful removal of a large bronchocele, in 1866, from a patient whose case had been pronounced hopeless by a number of able surgeons. Several other equally satisfactory results in formidable goitre operations were sufficient to establish the propriety of the procedure in certain cases, and to evoke from a leading surgical authority an admission to this effect, although, in a previous edition, he had declared that "no honest and sensible surgeon would ever engage in this horrid butchery." But, while the distant future may remember him solely in connection with this brilliant contribution to legitimate surgery, the present generation of medical men, so many of whom bear his signature upon their diplomas, will associate with his name the idea of a dignified and impressive, but delightful and magnetic presence; a voice whose sweetness attracted and whose eloquence enchained; a mind of generous breadth, wonderfully alert and fertile in ingenious expedients and a hand under whose delicate touch the lurking mysteries of disease came forth from their concealment.

The various communities in which he exercised his art with such success will long mourn for him as for one whose place cannot be supplied, and the benedictions of the multitude which almost worshiped him for changing their misery to joy will follow him to his ocean grave. The medical profession of his native State with gratitude acknowledges that to him, more than to any other in its ranks, it owes progress in knowledge, incentive to activity, and increase of achievement.

F. H. G.

MEDICAL NOTES.

— American beef is asserting itself in the British market. Its value was practically tested by the Edinburgh Parochial Board last month. Two masses of English and American beef, each weighing seventy pounds twelve ounces, were boiled, when it was found that the amount of good meat in each case was about the same, while the soup made from one was undistinguished from that made from the other. But in a contract of one thousand pounds there was a saving of one hundred pounds in favor of the American meat — a result which cannot but bring important conclusions to those who are interested in cheap meat, more especially in workhouse and hospital administration.

— The gratitude of patients to their doctors, though not often taking a practical shape, does sometimes do so, and in one recent instance was very touching.

Thomas Hobson, seventy-eight years of age, hanged himself in the workhouse. Before committing the act he made a will in which he bequeathed his body to the medical attendant, "in gratitude for his kindness and urbanity." The doctor, however, declined the bequest. A like reluctance has been shown by the School of Anatomy at Owens College, which was named as second legatee. — *London Correspondent of the American Practitioner.*

— The *Atlanta Medical and Surgical Journal* has changed its name to the *Atlanta Medical Register* simultaneously with a change in editorial management.

NEW YORK.

— The sixth annual meeting of the American Gynecological Society was held on the 21st, 22d, and 23d of the month at the hall of the Academy of Medicine in New York.

— The excursions of the floating hospital of St. John's Guild have now ended for the season. During the summer forty-two excursions were made, and 25,201 children and their mothers taken out upon the water for a day.

— Twenty-one milk-dealers were recently arraigned before the Court of General Sessions in one day and convicted of selling adulterated milk; it being shown that in some instances as much as 90 per cent. of the cream had been removed from the milk. Fines varying from \$10 to \$150 were imposed — the total amount of the fines being \$1,200; but it is evident that if this wretched traffic is to be interfered with to any extent, the fines should be greatly increased and imprisonment for a longer or shorter period added to the punishment.

Miscellany.

DR. HAMILTON ON THE AUTOPSY.

DR. HAMILTON makes the following statement in the daily press with regard to the autopsy: —

The ball entered the inter-vertebral space between the last dorsal and first lumbar vertebra, at a point very near the transverse and oblique processes; that is, obliquely from behind. It passed a little downward and forward, penetrating the body of the first lumbar vertebra; escaped from the vertebra very near the middle in front, and was found a little to the left of the body of the vertebra, lying under the lower margin of the pancreas, and nearer its posterior or dorsal aspect than its anterior, behind the peritoneum, and outside the cavity of the belly. The ball was encysted, completely surrounded by a firm capsule, which invested it entirely and closely, the capsule containing nothing but the ball. Perhaps a grain or two of white tenacious substance attached to the point of its inner surface, which was not easily removed by the edge of the knife, and which may be found under the microscope to consist of a drop of desiccated pus, or it may prove to be the leaden stain occasioned by the oxidation of the surface of the ball. It also contained a small fragment of black matter, perhaps three quarters of an inch in length and an eighth of an inch in breadth, which under the microscope may prove to be a piece of cloth, the exact character of which has not yet been determined. A most critical examination of this sac under a strong light and with a probe did not disclose any connection between it and the track of the ball. Not far removed from the seat of the ball was the blood cavity, perhaps distant one or two inches, and in this neighborhood could be felt distinctly under the finger innumerable small substances like grains of sand of greater or less magnitude, which have not yet been submitted to microscopical examination, but which were supposed to be minute fragments of bone torn away from the broken vertebra, and thus widely

disseminated in the adjacent tissues. The blood sac was behind the peritoneum, but the autopsy revealed that it had ruptured into the cavity of the peritoneum, probably just before the occurrence of death, and at least a pint of blood, coagulated, was found in the peritoneal cavity. The abscess spoken of in the official report of the autopsy was not in this region precisely, but somewhat more to the right, between the liver and the transverse colon. No connection was discovered between this and the external wound made by the bullet, and there are no means of knowing whether it communicated with the original track at some earlier period in the history of the case or not. It may have done so and become subsequently closed, or it may have been the result of the extension of inflammation from the original track to the adjacent tissues. There was no lesion of the liver, recent or ancient, indicated in the autopsy.

It was evident from this account that the presence of the ball in the situation in which it was found was not the immediate cause of death, as it was completely encysted, and must have long since ceased to cause irritation. The small fragments of bone and the great lesion of the lumbar vertebra are the pathological fact which alone could endanger the patient's life. This lesion of the vertebra the surgeons had no means of repairing, nor could it have been repaired save by the processes of nature. The small fragments of bone (if they should prove to be such), widely disseminated in the adjacent tissues, certainly could not have been removed by any surgical operation. It was determined by the autopsy that the necessity did not exist for removing the ball, or, in other words, that had there been no other lesion it might have been carried for many years without causing death or even inconvenience. Still, it may be proper to inquire whether by a surgical operation the bullet could have been safely removed. If it had been arrested by the spine, or even lodged in the substance of the spinal column, possibly, with a bold and very extensive dissection, it might have been reached and extracted. It is questionable, however, whether the history of surgery furnishes any example of success under the circumstance now supposed; but the fact is that the bullet traversed the spine and lodged at a point some distance removed from it, passing miraculously through various vital structures which surround the anterior and lateral walls.

The front of the spine in the region traversed, and both of its sides presenting towards the interior of the belly, are literally covered by important blood vessels, arteries and veins, the most important nerves of the body, including the sympathetic and ganglionic system of nerves, also nerves of common sensation and motion, and by absorbents, including the great thoracic, through which nutrition from the alimentary canal is conveyed to the heart. The injury of almost any one of the foregoing, excepting the nerves of common sensation and motion, would inevitably destroy life, and in the midst of this plexus of arteries, veins, and lymphatics, the surgeon would have had to carry his knife in search of a ball the situation of which has only been revealed by the autopsy. There were no possible means of knowing the situation of the ball during life, as it gave no indications of its presence, nor could it possibly have been reached and recognized by any form of surgical probe. That death would have been immediate, and the inevitable result of any such daring adventure, is almost absolutely certain. However much we, individually or collectively, may have made ourselves liable to just criticism in the matter of diagnosis or prognosis, and whatever doubts may be entertained by medical men as to the propriety of the treatment in certain respects, I cannot believe that one intelligent surgeon will hereafter think that at any period in the progress of the case the ball, or the fragments of bone which it sent before it, could have been successfully removed; nor, indeed, that any serious attempt in that direction would not have resulted in speedy death. Viewing the case in the light of our present knowledge, I am prepared to affirm that surgery has no resources by which the fatal result could have been averted. This was the sad consolation which I felt justified in giving to the grief-stricken wife and family, and which all my associates believe we can give to an afflicted people.

DR. BLISS'S SUMMONS TO TAKE CHARGE OF PRESIDENT GARFIELD.

IN reply to certain questions as to the manner in which he was summoned to take charge of President Garfield, Dr. Bliss has made the following statements, according to the daily press: —

The Secretary of War sent his carriage for me immediately after the shooting, with a message to take charge of the Presi-

dent's case until further orders. On arriving at the depot I was immediately conducted to the room where the President lay, and assumed charge of the case, feeling that I was there by proper authority. The history and conduct of the case is not pertinent until the following Sunday morning, when the President had fully reacted, had several hours of rest, was cheerful and competent to attend to any ordinary business, when I presented the matter of his professional attendance to him, Mrs. Garfield being present. I then explained to him fully the valuable professional assistance the large number of medical gentlemen had rendered up to that time, representing as they did the best medical talent in the city. His reply was, "Of course, doctor, it will not do to continue the large number of medical gentlemen in attendance; such a number of surgeons would be cumbersome and unwieldy." I said then, "Mr. President, it is your duty to select your medical attendants now." He replied: "I desire you to take charge of my case. I know of your experience and skill, and have full confidence in your judgment, and wish you to thank the doctors individually for their kind attendance." I thanked him, and replied that it would be necessary to select three or four medical assistants as counsel in the case. He replied: "I shall leave that entirely with you; you know what talent you require, and your judgment is best upon that point." I then selected in order the gentlemen who were immediately associated in the case, stating in each instance the reason for so doing. He said that was eminently satisfactory to him. I then turned to Mrs. Garfield and said: "If you desire to add one or more to the number selected I shall be happy to unite them to our counsel." Her reply was, "I would not add one to the number you have selected, and I want to say to you, doctor, that you shall not be embarrassed in any way in your future treatment of this case." Neither the President nor Mrs. Garfield, nor any member of the household from that time to the present, suggested the name of any other physician except the eminent counsel called from Philadelphia and New York. I desire to say at this time that Mrs. Garfield has conscientiously kept this promise to me throughout the entire case.

PREVENTING SPREAD OF CONTAGIOUS DISEASES.

WISCONSIN has recently passed a law to prevent the spread of contagious diseases, which makes any person suffering from small-pox, diphtheria, scarlet fever, and other contagious diseases, who willfully enters any public conveyance or public place, liable to a fine of fifty to three hundred dollars, or imprisonment for twenty to one hundred days. The same penalties are exacted of any one in charge of a child or irresponsible person who allows similar exposure. The conveyance of corpses into any city or town of the State is forbidden except when accompanied by certificate from a physician, stating cause of death; and, in case of decease from infectious diseases, a certificate must be shown from the health authority that proper precautions, by use of disinfectants or inclosure in airtight collins, have been taken. The penalties are the same as in the preceding case.

A similar regulation of the Iowa State Board of Health provides that bodies of patients dead from diphtheria, scarlet fever, and typhus or typhoid fever shall be placed in a wooden or metallic coffin, which can be inclosed by a tight wooden box closely wrapped in carbolized celloth or effective substitute. Bodies not dying from the diseases named may be transported without restriction from November 15th to March 15th, but the rest of the year are to be prepared as above described. Every body must be accompanied by a physician's certificate of death, transportation permit from the clerk of the local Health Board, and written certificate from the undertaker. The transportation of bodies dead from Asiatic cholera, yellow fever, and small-pox is absolutely prohibited. — *Sanitary Engineering*.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM SEPTEMBER 18, 1881, TO SEPTEMBER 24, 1881.

REED, W., captain and assistant surgeon. Assigned to duty with Light Battery A, Second Artillery, ordered to leave Washington Barracks, D. C., on September 20th, and march to Yorktown, Va. S. O. 165, Department of the East, September 16, 1881.

TAYLOR, A. W., first lieutenant and assistant surgeon. Assigned to duty as medical officer to escort conducting Little Chief and his band from Department of the Missouri to Department of Dakota. On return trip to leave the command at Sidney, Nebr., proceed direct to Fort Leavenworth, Kans., and report to the Medical Director of the Department. S. O. 188, Department of the Missouri, September 16, 1881.

BOOKS AND PAMPHLETS RECEIVED. — Text-Book of Modern Midwifery. By Rodney Glisan, M. D., Emeritus Professor of Obstetrics and Diseases of Women and Children in the Medical Department of the Willamette University, and late President of the Oregon State Medical Society. With one hundred and thirty illustrations. Philadelphia: Presley Blakiston. 1881.

Transactions of the American Gynecological Society. Vol. V. For the Year 1880. Boston: Houghton, Mifflin & Co. 1881.

Remarkable Change in the Color of the Hair from Light Blonde to Black in a Patient while under Treatment by Pilocarpin.

Report of a Case of Pyelo-Nephritis, with unusually prolonged Anuria.

Case of Membranous Croup treated Successfully by Pilocarpin. By D. W. Prentiss, M. D. Philadelphia: Printed by J. B. Lippincott & Co. 1881. (Reprint.)

Bacteria: the Smallest of Living Organisms. By Dr. Ferdinand Cohn, Professor in the University of Breslau. Translated by Charles S. Dolley. Rochester, N. Y. 1881.

Convulsions due to Depression of Spinal Reflex-Inhibitory Centres, with special reference to the Convulsions of Apomorphine, Atropine, Strychnine, and other Poisons. By Edward T. Reichert, M. D. (Reprint.)

Ethylene Bichloride as an Anæsthetic Agent, with a Consideration of Ethylene Methylethylate, Ethylene Ethylate, Ethyl Nitrate, Ethylidene Bichloride. By Edward T. Reichert, M. D. (Reprint.)

Female Diseases the Result of Errors in Habit and Hygiene during Childhood and Puberty, with Remarks on the Treatment of Rachialgia with Iguir-Puncture (Piquelin's Cautery). By R. J. Nunn, M. D., Savannah, Ga. (Reprint.)

Sanitary Association of Lynn. Second Annual Report of the Executive Council.

Electro-Massage. By John Butler, M. D. (Reprint.)

Indigestion, Biliouness, and Gout in its Protean Aspects. Part I. Indigestion and Biliouness. By J. Milner Fothergill, M. D. New York: D. Appleton & Co. 1881.

The Applied Anatomy of the Nervous System, being a Study of this Portion of the Human Body from a Standpoint of its General Interest and Practical Utility, designed for Use as a Text-Book and a Work of Reference. By Ambrose L. Ranney, M. D. With numerous illustrations. New York: D. Appleton & Co. 1881.

Inaugural Address. By Reginald Harrison, F. R. C. S., President of the Liverpool Medical Institution.

Importance of the Early Recognition of Epilepsy. An Essay read before the Connecticut State Medical Society, May 26, 1881. By E. C. Seguin, M. D. (Reprint.)

A Second Contribution to the Study of Localized Cerebral Lesions. By E. C. Seguin, M. D. (Reprint.)

Sarcoma of the Choroid, Ciliary Body, and Iris. By J. S. Pratt, M. D., Brooklyn, N. Y., and Charles S. Bull, M. D., New York. (Reprint.)

— The American Surgical Society held its first annual meeting on the 13th, 14th, and 15th of September at the Oriental Hotel, Coney Island. Owing to the absence of an unusually large number of prominent surgeons in Europe this year, the attendance was not as full as it probably will be at future sessions.

Original Articles.

THE VITAL STATISTICS OF MASSACHUSETTS
FOR 1880.¹

BY CHARLES F. FOLSOM, M. D.

BETWEEN the census years 1875 and 1880 the increase of the population was 131,173, or 63,388 less than in the preceding period of five years, a fact largely due to the extreme industrial depression just gone by. With an increase of population to 1,783,085 from 1,651,912 in 1875, there were recorded in 1880, 41,247 births, 15,538 marriages, and 35,292 deaths, or 3922 more births, 1736 more marriages, and 3191 more deaths than in the previous year. The excess of living births over deaths was 8925, showing a natural increase of the population exceeding that of 1879 by 431.

The rates for the year to 1000 of population are: births 24.80; marriages 8.71; deaths 19.79; excess of births over deaths 5.01, showing a natural increase of the population much below the average, the rates of excess of birth-rate over death-rate for thirty years, in periods of five years, beginning with 1851, being 10.1; 11.6; 4.7 (8.3 excluding the years most influenced by the war); 7.9; 6.8; 5.6.

BIRTHS.

The birth-rate for 1880 is, although slightly higher than for the previous two years, 2.23 per 1000 lower than the average for thirty years or than any other years except 1863, 1864, 1865, 1878, and 1879, the decrease being most marked in those counties where there is the least concentration of foreign laborers; the birth-rate, too, is largest in the large towns, varying from nearly 30 per 1000 in towns of 50,000 population and over, to 16.94 in those of 2000 and under. By seasons, 23.3 per cent. of the births were in the first quarter of the year; 24.6 in the second; 26.3 in the third; 25.8 in the fourth; the same figures for a period of fifteen years being 23.03, 23.43, 26.75, and 26.79. There were 105.9 births of males to 100 of females, which is also the average for twenty-five years. The still-births of males are to those of females as 138 to 100, or for twenty-five years 149 to 100.

As regards parent-nativity, Barnstable County, at one extreme, shows five births of native parents to one of foreign; at the other, in Suffolk County, one third more is of foreign parentage than of native. Of the 778 illegitimate births Suffolk County has one half, although containing only one fifth of the population of the State.

MARRIAGES.

The marriage-rate is greater than for any other year since 1874, but 1.68 per 1000 less than the average for thirty years, and .17 less than the average of the three years most influenced by the war. It is nearly 2 per 1000 greater in the sixteen large towns than in the rest of the State, and generally speaking increasing with the concentration of the population. As usual, the greatest number of marriages, 1857, was in November, the least, 799, in March. The average relation of the seasons was maintained very closely,

21 per cent. of the marriages being in the first quarter, 25.82 in the second, 22.20 in the third, 30.98 in the fourth. The average age of 15,501 men married during the year was 28.9 years; of 13,121 men marrying for the first time 26.5 years; of 15,185 women married, 25.1 years; of 13,956 women marrying for the first time, 23.8 years. There were 12,119 bachelors married to maids, 702 bachelors to widows, 1531 widowers to maids, 807 widowers to widows. The youngest person married was 13 years old, the oldest 82.

DEATHS.

The number of deaths in 1880 (namely, 35,292) was considerably in excess of that of any year of the previous quarter of a century. The rate per 1000 of the population (19.79) was the greatest since 1876, was .53 greater than the average for thirty years, and .57 more than the rate of the last quinquennial. It was exceeded only seven times since 1850, including the two years most influenced by the war. The death-rate was considerably greater than for either of the previous three years, but 1.03 less than the average for the five years 1871-1875. In the last decennial it was exceeded four times, 1872, 1873, 1875, and 1876. Four years, 1871 and 1877-1879, showed lower rates, and in 1874 the percentage was the same as in 1880. Although these rates depend very largely upon the number of births, and therefore upon the number of infants in the population, the mortality of children under one year of age being from one fifth to one fourth of the total number of deaths, yet they are also largely influenced by various epidemics, which are chiefly fatal among children under five, their mortality being from one third to two fifths of the whole. The year has been, therefore, one of less than the average good health, and considerably lower than the previous three years in that respect. The very fatal epidemic of diphtheria has continued, with even a moderate increase over 1879; the diarrhoeal diseases of infants have caused much greater mortality than for the preceding two years, the infectious diseases generally have risen to a higher number, and pneumonia has been excessively fatal. The greater number of deaths in 1880 has been recorded at nearly all ages, but to the greatest extent in infants and young children.

The death-rates of the several counties were: Norfolk and Franklin 16.1; Berkshire 16.4; Plymouth 16.8; Hampshire and Middlesex 18.1; Worcester 18.9; Barnstable 19.0; Hampden 19.9; Essex 20.2; Bristol 21.4; Dukes and Nantucket 21.8; Suffolk 23.4; of the larger cities, Fall River 26.3; Holyoke 24.0; Boston 23.7; Gloucester and Salem 23.2; Lowell 22.0; New Bedford 21.9; Lawrence 21.6; Worcester 20.9; Chelsea 20.5; Lynn 19.5; Springfield 19.0; Taunton 18.6; Cambridge 18.0; Somerville 17.0; Newton 15.8; of the sixteen cities 22.1, and of the rest of the State 18.6; of towns of 20,000 to 30,000 population 20.95; of those of 10,000 to 20,000, 17.88; 5000 to 10,000, 18.34; 4000 to 5000, 17.48; 3000 to 4000, 16.90; 2000 to 3000, 16.99; 1000 to 2000, 16.71; less than 1000, 19.85.

The greatest monthly number of deaths (3581) was in August; July, September, December, March, April, October, May, November, January, and February following to 2497 in June; by quarters the percentages were 28.6 per cent. in the third, 24.5 in the fourth, 23.5 in the first, 23.4 in the second.

The deaths of females exceeded those of males in

¹ An abstract from the advanced sheets of the Thirty-Ninth Report to the Legislature of Massachusetts, relating to the Registry and Return of Births, Marriages, and Deaths in the Commonwealth for the Year Ending December 31, 1880. Prepared under the direction of the Secretary of the Commonwealth. Boston. Rand, Avery & Co., Printers to the Commonwealth.

1880 by 426 as compared with 514 in 1879. In 14 deaths the sex was not reported.¹ The death-rate of males has exceeded that of females in the four census years 1865-1880 by 2.1, .9, 1.3, and 1.0, the averages of the four years being, for males 20.8 and for females 19.5 per 1000 living. From the age of 20 upwards, and in the total number for all ages, the absolute number of deaths of females in the State is greater than that of males, especially during the ages from 20 to 30, while the opposite fact is true in the early years of life, which is most marked in infancy. The infant mortality was 20.1 of the whole, that of children under five years of age 34.6.

The average age at death varies very much in the different counties, dependent very largely upon the numbers of persons dying in the early years of life, and, consequently, upon the character of the population. The improvident and very poor, who have the largest families, show also the greatest infant mortality, which diminishes the average duration of life enormously, and they also are themselves exposed to causes of early death. As would be expected, therefore, the lowest average age at death for a period of thirty years is, in Suffolk County, 23.34, the highest in Dukes and Nantucket, 46.31, followed in order by Franklin, 38.58, Barnstable, 36.97, Plymouth, 36.24, Hampshire, 35.16, Berkshire, 33.61, Norfolk, 30.95, Worcester, 30.82, Bristol, 30.03, Essex, 29.30 (which is very nearly the same as that of the State, 29.35), Hampden, 27.94, Middlesex, 27.86.

CAUSES OF DEATH.

Of the 35,292 deaths reported in 1880 in the State, the causes of death failed to be certified in 745, or 2.13 per cent., leaving 34,547 in which the facts required by law were ascertained. The deaths reported with causes not specified diminish from year to year in number, and still more in their proportion to all the deaths reported, having dropped from 1464 in 1868 quite progressively to 775 in 1879, except that for 1872 and 1873 there was a rise. Of the 745 unspecified causes of death in 1880, there were 108 deaths from hemorrhage, 86 from tumor, 34 from inflammation, and 517 in which the returns give not even a statement as to any of supposed causes of death. As compared with the population, the unspecified causes of death in 1880 were .42 per 1000, while they were .41 in 1879, and 1.06 in 1868.

There is a decided increase in zymotic and local diseases over the previous year, the constitutional diseases having been far less fatal than in 1879. The deaths from violence, also, were less numerous. Leaving out of consideration the unspecified causes of death, the "zymotic diseases"—those commonly considered to represent the sanitary condition of places—were 2.3 per cent. less than the average proportion for ten years; the constitutional .7 less, but also less than for either of the previous three years. The local diseases were 6.0 higher than the average per cent., developmental diseases 2.6 less, and violent deaths .5 less than the average.

The most destructive nine so-called zymotic diseases,

or infection-diseases, caused a much larger number of deaths than in 1878 or 1879, although in comparison to the population, far less than in any of the previous years except 1871, and at a less rate per 1000 of population even than in that year. Whooping-cough and scarlet fever were much less fatal than common, and show a marked reduction as compared with 1879. The other prominent "infection-diseases" caused a larger number of deaths than in the previous year, the advance being most marked in cholera infantum and measles, but also very great in typhoid fever, 245 more deaths from the last-named disease having occurred than in 1879, and more than for any one year since 1875. There was also a marked increase in diphtheria and croup, making 1880 the third year in mortality from that cause. From the nine diseases the total number of deaths in 1880 was 381 less than the average for ten years, in spite of a largely increased population.

The constitutional diseases, less fatal in 1880 than usual, continue to show an increasing rate from cancer and decreasing mortality from consumption,—a fact which may be largely due to more accurate certifying of causes of death and better diagnosis.

The principal local diseases all caused more deaths than in 1879, and, with the exception of pleurisy, more than in any previous year. The increase has been most striking in bronchitis (chiefly in infants and very young children), and in Bright's disease and peritonitis (due, to a great extent, to more accurate diagnosis). Pneumonia has increased at a faster rate than the population, as have also apparently heart diseases. The increase from "convulsions," an obscure term, is not so great in proportion as the population; while insanity, apoplexy, and paralysis together mark a strikingly larger number of deaths.

In developmental diseases it is gratifying to find the obscure expression "teething" less from year to year, and that the latter years show a more favorable record in the decenniad than the earlier as regards still-born, "infantile," premature deaths, and deaths from child-birth.

The violent deaths caused in 1880 the least mortality of the decenniad; and this was most marked in the suicides and deaths by drowning, while the homicides were quite below the average. The deaths from poison were in great excess, and from railroad accidents more than in any other of the ten years except 1871.

The order of fatality of the twelve causes producing the greatest number of deaths places consumption easily at the head of the list as usual. Pneumonia is second, as it was the previous two years, and in 1874 and in 1875; it was third in 1872, 1873, 1876, and 1877, always a leading source of mortality in our State. Cholera infantum, from having steadily fallen from the second place in 1872 and 1873, the third in 1874 and 1875, the fourth in 1876 and 1877, fifth in 1878, and sixth in 1879, has risen in 1880 to the third. Heart disease, not always an exact term, was, as last year, fourth, having been only sixth to eighth in 1878 and the preceding six years. Diphtheria stands fifth, having declined from the second place in 1876 and 1877, and third in 1878 and 1879; if croup were included with it the deaths would be 2391 instead of 1769, and its place would be third. Old age is sixth, being fourth or fifth previously since 1872. Paralysis is now for the fourth year seventh. Cancer has risen from tenth, eleventh, and twelfth places to eighth, as it was also in 1879. "Cephalitis" was ninth in 1880; bronchitis,

¹ A comparison of the United States census of 1880, the excess of females over males being 18,962,000, 24,945,000, or 8,983,000, as compared with 18,943,000, 24,945,000, or 8,983,000, in 1870, and 18,943,000, 24,945,000, or 8,983,000, in 1860. The rate of increase of the population was in 1880 very nearly the same as in 1870, 18.7 per cent., 19.7 per cent., as compared with 19.7 per cent. in 1870, and 19.7 per cent. in 1860.

as in 1879, eleventh. Typhoid fever showed an extraordinary decline from the fourth place in 1872, sixth in 1873, seventh in 1874, eighth in 1875 and 1876, ninth in 1877 and 1878, to *thirteenth* in 1879, and has now risen again to tenth.

In infancy and early childhood the diarrhoeal diseases of the hot months, diphtheria, pneumonia, and obscure diseases ("convulsions" and "cephalitis"), largely of the central nervous system and of the digestive organs, prevailed. From five to ten, infectious diseases were most fatal, obscure brain troubles and pneumonia following. From ten to fifteen consumption and typhoid fever appear as prominent causes of death. From fifteen to twenty consumption caused nearly one half of all deaths, and heart disease is prominent. From twenty to thirty consumption caused more than one half of all the deaths, and childbirth is fifth in order. In the next four decades of life pulmonary consumption, although first in order, occupies a position of progressively less importance. Pneumonia is second, and heart disease third. Typhoid fever becomes of less importance, Bright's disease, cancer, and apoplexy of more. Childbirth is the *sixth* from thirty to forty, and then ceases to be a leading cause of death. Over seventy, old age, pneumonia, paralysis, apoplexy, and heart diseases are the prominent five causes of death.

The deaths in 1880 between the ages of ten and fifteen were 611 as compared with 616 in 1879; at all other ages the deaths were more. Under the age of five they were 2051 more. From five to ten the excess was 51; 28 from fifteen to twenty; 313 from twenty to thirty; 177 from thirty to forty; 90 from forty to fifty; 226 from fifty to sixty; 277 from sixty to seventy; 143 from seventy to eighty; 336 for the ages of eighty and over.

DIPHTHERIA.

Thirty pages of the report are devoted to an analysis of the 18,714 deaths from diphtheria (including croup) in this State during the ten years ending in 1880, by years, months, ages, sex, and population, with the death record from that cause for each city and town in the State. There were 9249 deaths of males, 9459 of females; 747 in 1871; 753 in 1872; 745 in 1873; 913 in 1874; 1880 in 1875; 3294 in 1876; 3178 in 1877; 2517 in 1878; 2293 in 1879; 2394 in 1880; 2337 in November; 2307 in December; 2109 in January; 2098 in October; 1611 in February; 1560 in March; 1350 in April; 1269 in September; 1225 in May; 1045 in June; 916 in July; 887 in August.

The deaths under five years of age were 65 per cent. of those at all ages, and from five to ten they constituted 25 per cent.; 90 per cent. of the deaths occurred in children under ten years of age, or 95 per cent. under the age of fifteen, the decline from that age onward being progressive and quite marked. As compared with the population at the several ages, there was an annual average mortality of 69.96 per 10,000 under five years of age; of 28.33 from five to ten years; of 6.74 from ten to fifteen; of 1.52 from fifteen to twenty; and from .82 to .39 for all other ages.

The analysis of the deaths from diphtheria and croup for the ten years indicates a sudden rise in 1874, chiefly in Berkshire and Franklin counties, corresponding to the beginning of the severe epidemic in the northwestern part of the State, with independent lesser foci in Bristol, Middlesex, and Hampden, while the deaths

from that cause were less than the average of the previous three years in Barnstable, Essex, Dukes and Nantucket, Norfolk, Plymouth, Suffolk, and Worcester. In 1875 the epidemic in Berkshire and Franklin counties continued, and there was a marked rise in every other county in the State except the islands, where no deaths were reported from diphtheria or croup. In 1876, the epidemic had decidedly moderated in Franklin County and less so in Barnstable, while the increase in the rest of the State except the islands was very great, causing 3294 deaths, or 116 more than in the next year, from which time there has been a decline, Suffolk County alone having a greater number of deaths in 1880 than in any previous year.

Following the different towns in the list, it is seen that the mortality varied greatly from year to year in some; that in many it could hardly be said that there was any real epidemic; that the excessive mortality occurred in one season as in Florida, in two as in Nantucket, or scattered over any or nearly all of the ten years, and that contiguous towns were often visited by the disease with very different degrees of fatality. In the northern part of Berkshire County the epidemic was much more severe than in the southern part, while the opposite fact is true of the towns forming the Connecticut valley. The extremely small towns of Florida and Conway had the highest death-rates in Berkshire and Franklin counties, Easton (population, 3898) in Bristol, Haverhill (11,628) in Essex, Holyoke (16,260) in Hampden, Ware (4142) in Hampshire, Pepperell (1927) in Middlesex, Sharon (1330) in Norfolk, Plymouth (755) in Plymouth, Chelsea (20,737) in Suffolk, Spencer (5451) in Worcester. The variations in the death-rates (0 to 34.96) and in the duration of the prevalence of the disease are excessive.

Leaving out the two very small counties, Dukes and Nantucket, the highest rates from diphtheria and croup are in rocky, bleak Essex, forming our northeast coast, and Hampden at the lower part of the valley of the Connecticut, largely on alluvial deposit; the most densely populated county of Suffolk, with the highest mortality from all causes in the State, comes next, followed by Berkshire, where the general conditions of health are the most favorable; Middlesex in the north and Bristol at the south are side by side in the table, as are Franklin, high up in the interior of the State, and Barnstable, the extreme cape. In the cities and towns, some of the decennial rates per 1000 by the census of 1875, representing annual average rates per 10,000, are (1) Florida 34.96; (329) Sheffield 45 (two small towns in the extreme north and south of Berkshire County); (6) Holyoke 22.82; (7) Nantucket 21.87; (8) Haverhill 20.24; (9) Williamstown 20.09; (15) Marblehead 17.72; (21) Gloucester 17.25; (22) Lynn 17.18; (36) Lowell 15.88; (37) Hull 15.82; (41) Waltham 15.45; (12) Lawrence 15.41; (14) Salem 15.26; (50) New Bedford 14.64; (52) Pittsfield 14.35; (58) Brookline 13.93; (68) Milton 13.15; (74) Beverly 12.79; (75) Plymouth 12.56; (77) Somerville 12.44; (80) Princeton 12.23; (81) Boston 12.21; (87) Winchester 11.71; (90) Fitchburg 11.64; (93) Springfield 11.43; (94) Dalton 11.37; (95) Cambridge 11.31; (101) Northampton 11.16; (104) South Abington 10.99; (108) Wayland 10.76; (109) Worcester 10.73; (111) Lenox 10.30; (113) Manchester 10.25; (114) Brockton 10.20; (123) Fall River 9.66; (130) Rockport 9.15; (146) Andover 8.44; (158) Winthrop 7.97; (163) Belmont 7.74; (168) Newburyport 7.58;

(176) Lexington 7.19; (179) Dedham 6.95; (187) Medford 6.49; (199) Woburn 6.27; (200) Revere 6.21; (201) Natick 6.20; (211) Concord 5.61; (227) Mattapoisett 5.14; (237) Duxbury 4.90; (242) Clinton 4.72; (248) Leominster 4.61; (256) Petersham 4.16; (261) Nahant 3.92; (267) Barnstable 3.72; (268) Provincetown 3.67; (296) Stockbridge 2.39; (300) Dunstable 2.21; (313) Great Barrington 1.59; (322) Wenham 1.10; (330) Lincoln 0.

The least average mortality is in the 83 small towns of less than 1000 inhabitants, namely 5.61; in those of 1000 to 2000 (98) it was 7.29; in 49 of 2000 to 3000, 8.02; in 33 of 3000 to 4000, 10.98; in 23 of 4000 to 5000, 9.49; in 30 of 5000 to 10,000, 11.30; in 12 of 10,000 to 20,000, 14.22; in 5 of 20,000 to 30,000, 13.65; in 3 of 30,000 to 40,000, 14.75; in 4 of 40,000 to 50,000, 11.96; in 1 of 341,919 (Boston), 12.21; in the State, 11.33.

The average of the death-rates of the towns having in their population the greatest proportion of young children was higher than in those having fewer of them; but there were many exceptions to that rule, and the town having the largest proportion of children under five years of age had a low death-rate from diphtheria and croup (5.26) while the town having the smallest proportion of children under five years of age had a rate of 21.87.

After the epidemic of diphtheria and croup, which reached its highest point in 1863, the deaths from that cause declined steadily from 8.17 per cent. of the total mortality to 2.5 in 1870, rising slightly to 2.7 in 1871. In 1875 the annual increase was great; and in the next two years the epidemic was at its greatest height, from which time there has been a steady decline to 6.78 per cent. in 1880. Diphtheria appeared first in our death-returns under that name for the first time in 1858, although it prevailed earlier in our State, and has been known to the world for at least twenty centuries. Many authorities consider it as the severe form of what has been known for many years as the disease "membranous croup." The two diseases are at least confused in practice, and are considered in the Report as belonging together.

REPORT ON PROGRESS OF THERAPEUTICS.

BY ROBERT AMORY, M. D. (HARV.), LONGWOOD, BROOKLINE.

BENZOIC ACID IN POLYARTHRITIS RHEUMATICA.

SENATOR,² in confirmation of his observations with the use of this drug, remarks that benzoic acid or benzoate of soda has no remedial action of any value in chronic cases of arthritic rheumatism, nor in the subacute non-febrile attacks. Of twenty-two acute cases, however, in which he used this medicinal agent solely, one was relieved in two days, twenty in less than four days, and one in not less than eleven days, and none of these cases had any relapse or complication. Though it is the experience of the unprejudiced general practitioner that there are certain cases in which almost any simple method of treatment apparently produces a relief early in the attack, and to such a surprising degree that he is often led to believe that these exceptional cases would do well even without medicinal treatment, yet Senator, who was at one time rather

skeptical of the value of salicylic acid in rheumatism, seems to believe that the favorable result in the above twenty-two cases was clearly due to the administration of benzoic acid, and he was further convinced of this fact by another small group of cases, four in number, in which the use of salicylic acid had produced no remedial action, and yet afterwards its discontinuance and the administration of benzoic acid produced a rapid cure. In another group of six cases the use of benzoic acid was not followed by relief of symptoms, while the salicylic produced a beneficial effect. Fourteen cases were also treated by salicylic acid and benzoic acid together, in which he was inclined to give the preference to the use of the former. He recommends that benzoic acid, which can be given in very large doses (fifteen grammes, or four hundred and thirty grains, per diem), should be given in those cases in which salicylic acid has failed to give any relief.

BENZOIC ACID IN RHEUMATISM.

Senator³ finds that this remedy will speedily abbreviate an attack of articular rheumatism, provided it is unattended with fever and is not subacute; in these cases it seems to have but slight effect. No complication or relapse follows either this acid or its soda salt (benzoate of soda) after producing relief to rheumatic pains. He gives ten or twelve grammes of the acid and twelve to fifteen grammes of the benzoate of soda.

BROMIDE OF POTASSIUM IN INFANTILE DENTITION.

M. Peyraud⁴ recommends this drug for relief to the painful and troublesome processes of infantile dentition, and employs the following prescription:—

℞ Bromide of potassium	2-3 grammes.
Honey	15-20 grammes.
Water	q. s.

After the solution has taken place heat and evaporate to a consistency of honey, adding alcohol to preserve the mixture. By rubbing this upon inflamed gums the mucous membrane is attacked and denuded, the hyperæmic circulation is diminished, the inflammation reduced, and the projecting points of the teeth will gradually pierce the gum, and the contemporaneous inflammation of the mouth will be subdued.

The internal use of this drug will likewise, in the author's experience, prevent or abate the convulsions incidental to teething infants. He also recommends the use of the bromide in dental caries, which it arrests, and acts as a substitute for the arsenical preparations commonly used by dentists. Into a little cyst of the eyelid M. Peyraud injected subcutaneously a strong solution of the bromide, which was followed by the complete disappearance of the cystic tumor.

M. Joffroy,⁵ basing his treatment on the ground that there is a hypersensibility of the mucous membrane of the larynx in the so-called spasm of the glottis after diphtheria, employed bromide of potassium in daily amounts of two grammes to overcome this hyperæsthesia. In two cases where asphyxia was threatened after tracheotomy had been performed, the spasm seemed controlled by the bromide, and death apparently was averted. He cautions against the use of this agent where there are complication of bronchitis or threatening paralysis of the glotto-pharyngeal and laryngeal muscles.

JABORANDI AND PILOCARPIN.

In an abstract of a paper by Dr. Erich Harnach and Dr. Hans Meyer,¹ of Strasbourg, contained in *New Remedies* for November, 1880, an assumption is made that there are two alkaloids contained in jaborandi. According to these authors, the alkaloid pilocarpin can be subdivided chemically; one of these subdivided elementary alkaloids has a physiological action closely simulating that of atropine. Calling this substance jaborine, he says of it that it is more soluble in ether, but less so in water, than the true pilocarpin, and the chloroplatinate of jaborine is more easily soluble in alcohol than is the case with pilocarpin; moreover, the jaborine salts are non-crystallizable.

What interests us therapeutically more closely is the fact that jaborine, like atropine, paralyzes the cardiac plexus of the pneumogastries. Jaborine is easily formed from pilocarpin, especially in the concentration of its acid solutions, or by heating a mixture of pilocarpin and hydrochloric acid in a sealed tube, or even by heating pilocarpin itself. Langley, in *Journal of Physiology*, has observed that the application of an extract of jaborandi leaves produced irritation in the terminal of the pneumogastric nerve of a frog's heart, while the application of pilocarpin produced paralysis just in the same way as that of atropine; in this effect pilocarpin closely resembles nicotine, but during the process of preparing his sample of pilocarpin jaborine was formed, and to this substance should be attributed the paralyzing effect of the drug, for if a mixed pilocarpin and jaborine be locally applied the effects of the latter predominate in producing a cardiac paralysis. Our authors found that the commercial fluid extract of jaborandi is free from jaborine, but on evaporating the alcoholic and acidulated solution of an extract, as, for instance, when attempting to separate pilocarpin, a notable quantity of jaborine will be formed.

This discovery, therefore, of Messrs. Harnach and Meyer may be of great therapeutical importance in the application of pilocarpin to the treatment of diphtheria. Undoubtedly, from the experience of many competent practitioners, this drug has a direct remedial effect upon the pseudo-membrane, whilst, on the other hand, some physicians have found the tendency to a general constitutional collapse from cardiac paralysis a serious contra-indication to the use of pilocarpin in this dread disease. If, therefore, the sialagogue effects of jaborandi can be obtained without cardiac sedation a great step forward may be made.

PILOCARPIN IN DIPHTHERIA.

Dr. George Guttman, of Cronstadt² writes that promising from the action of this drug upon bronchial catarrh that the same moistening of the mucous membrane would follow in use in membranous deposits upon the larynx with producing inflammatory action, he employed pilocarpin in sixty-six cases of diphtheria (rach-enbraune); fifteen of these exhibited the worst symptoms of diphtheria, of which at least two thirds, according to previous experience, would have died; thirty-three bad cases had an extensive membrane, the others being slight. He gave pilocarpin to all, and in the first cases associated this treatment with quinine and gargles only; they recovered in periods, as a rule, varying from

twenty-four hours to three days; of the fifteen worst cases, two recovered in nine and eleven days, the rest in two to five days. All patients who came early under treatment, while the pseudo-membrane was still loosely adherent, without exception, were cured in twenty-four hours. The doubt that these cases were not truly diphtheritic is not to be raised, since they were examined with the utmost care, and in the worst cases the contagion could be distinctly traced. Under the action of pilocarpin not only were the membranes and infiltration dissolved in the salivary flow, but also the violent inflammatory condition yielded to its influence, the deeply reddened, dry mucous membrane soon became moist, pale red, and in every respect of normal appearance. In two cases of violent tonsillitis in which the passage was so much reduced on account of swelling that water could scarcely be swallowed, the swollen condition disappeared after the use of pilocarpin and simultaneously also the inflammatory symptoms. In the administration of the remedy Dr. Guttman recommends the addition of pepsin to combat the gastric catarrh usually associated, and presents the following formula:—

R̄ Pilocarpin muriat	gr. $\frac{1}{3}$ to $\frac{2}{3}$.	
Pepsinæ	gr. j. to $\frac{1}{4}$.	
Acid hydrochloric	gtt. ij.	
Aque destillatæ	3 iijss.	M.

Sig. A teaspoonful hourly for children.

R̄ Pilocarpin muriat	gr. jss.	
Pepsinæ	gr. xxx.	
Acid hydrochloric	gtt. iij.	
Aque destillatæ	3 viij.	M.

Sig. A teaspoonful half hourly for adults.

He has never observed any undesirable effects of the drug even when it has been continued until complete recovery, possibly because he directed a small amount of generous wine to be given after each dose.

The attention of the readers of this journal is called to the experience of Dr. Vogel with the use of pilocarpin in diphtheria reported last winter.

Dr. Lax³ has also tried the effects of this drug upon diphtheria during a recent epidemic. He had sixteen cases, six of which had local application of a four per cent. solution of argentic nitrate, and used a gargle of chlorate of potassium; four of these children recovered and two died, the latter being bad cases. The remaining ten were treated by pilocarpin, six of these cases being very serious and two were expected to die any night; yet all made a good recovery. Increased secretion of salivary and mucous secretions caused large masses of false membrane to be expelled by the mouth and nose, respiration becoming freer, fever diminishing, and appetite improving. The children improved visibly in three to five days after the appearance of a labial herpes which was in each case the precursor of a recovery. The same formula recommended by Dr. Guttman was employed by Dr. Lax.

It would add largely to the value of remedies in diphtheria if practitioners would record whether their cases successfully treated by this or any other drug were under observation during the approach or at the close of an epidemic of diphtheria, as we all know that during the latter portion the cases of diphtheria are milder, and show a tendency to spontaneous recovery unless the treatment be too harsh. According to the best statistics which are at hand, namely, those of our own city of Boston, two thirds of all reported cases recover, and the remaining one third end fatally.

ANTAGONISM OF Pilocarpin and Muscarine, OF ATROPIA AND ACONITIA, AS INFLUENCED BY TEMPERATURE OF THE SEASON, BY SYDNEY RINGER.¹

Dr. Ringer having noticed in October a different result in the study of the action of these drugs as opposed to each other upon the character of cardiac pulsations from the results of his observation during the preceding July, subjected some frogs to various temperatures during the succeeding winter, and tried the effects of a local application of the drugs upon the muscular structure of their hearts, and concluded:—

(1.) The antagonism of pilocarpin and extract of muscaria on the frog's heart varies in different months.

(2.) In the summer months pilocarpin always strongly antagonizes extract of muscaria, but in the winter months there is often no antagonism, and even when it occurs it is generally slight.

(3.) This difference is due to temperature, for if in the winter months frogs are kept for several days at 60° F., the antagonism becomes well marked, and, indeed, as strong as in the summer months.

(4.) This seasonal difference in the antagonism of these two agents suggests that in summer and winter, respectively, there is a difference in the composition of the protoplasmic molecules of the cardiac structure of the frog's heart.

We must not, however, lose sight of the fact that in hibernating animals during hibernation the rapidity of absorption by imbibition may, and probably is, very much retarded in cold-blooded animals; therefore it is not impossible that Dr. Ringer's observations should be qualified by this factor, and by it the negative effects of the drugs might be explained. This is the more probable if we study in the same light the results of his observations on the antagonism of atropia and aconitia under the influence of temperature, for here he says, "that the antagonism is well marked in the warm months, and is absent in the ventricle (which is the larger mass of muscular tissue) in the cold months." Pantelejeff² finds that the "antagonism of atropine for quinine on the frog's heart is affected by the time of year. In summer frogs quinine arrests the heart in diastole, and atropia causes the heart at once to resume its pulsations. In winter frogs quinine arrests the heart much more slowly, whilst atropine, instead of obviating, actually increases this arrest." Perhaps this latter apparent exception to our criticism may be caused by the mechanical effects of the local application of a substance to the cardiac substance. It is hardly proper to compare this method of experimentation by local application of substances to a frog's heart with that of clinical experience, or to the more crucial experiments of a proper natural administration of medicinal substances to healthy, warm-blooded animals. Therefore without the slightest endeavor to detract from Dr. Ringer's experiments, a little skepticism may provoke a more extended experimentation. Physiological experiments with drugs used upon cold-blooded animals without clinical observation and comparison by the bedside should be mistrusted.

— Dr. H. Augustus Wilson has been appointed as attending physician to the Philadelphia Presbyterian Hospital in the place of Dr. De F. Willard, who lately resigned.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

CASES IN THE SERVICE OF DR. A. L. MASON.

REPORTED BY DR. WITHINGTON, HOUSE PHYSICIAN.

CHRONIC ULCER OF THE STOMACH; VENOUS THROMBOSIS; PULMONARY EMBOLISM; AUTOPSY.

JOHN S., aged twenty-eight, single, born in Ireland, a marble-polisher by trade, entered the hospital April 9th. He had been in good health till about a year before, when he began to feel weak and tired. Soon after he began to vomit after nearly every meal. The vomiting occurred usually about four hours after the ingestion of food, and was preceded by nausea and by a dull pain in the epigastrium. The vomitus was of a dark brown color. After a month or so the vomiting became less frequent, but the symptom continued until two months before admission, causing great pallor and emaciation. For the last six months he has been confined to bed. Though the vomiting has stopped, the pain still continues, and is of a dull character. Six weeks before entrance he had oedema of both legs, which after two weeks began to diminish, but returned a fortnight ago in the left leg. There has been slight palpitation of the heart with dyspnoea of late.

The patient's appearance was one of extreme anaemia; lips almost colorless. The left leg was oedematous throughout its whole extent, and was in marked contrast to the right one, which, like the rest of the body, was considerably emaciated.

Auscultation showed a moderate amount of oedema at the base of both lungs. A loud murmur in the first sound of heart in second left interspace; also heard to apex apparently anemic; loud venous hum in the neck; no apparent enlargement of the liver or spleen; percussion tympanitic in abdomen, extending well over the hepatic region; the urine was pale, acid, without albumen; specific gravity 1010. Soon after entering patient vomited for the first time in two months; no blood in the vomitus.

Two or three days later the tympanitic resonance in the neighborhood of the stomach became more marked with considerable epigastric tenderness; the appetite was very poor. An examination of the blood was made and the average of four counts gave 1,127,500 red corpuscles to the cubic millimetre; the white corpuscles not increased.

April 14th he began to fail rapidly without any special symptoms, the heart sounds remaining of fair strength. During the night the breathing suddenly became rapid and labored. He tossed about trying to get his breath and died at 3.30 A. M., April 15th.

Autopsy, twelve hours after death. The heart was distended by rather fluid blood; very anemic, with fatty degeneration marked in inter-ventricular septum and in papillary muscles; the lungs on section showed great oedema; at the secondary division of the pulmonary artery on the right, an embolus, dense and very adherent, wholly occluded the vessel at this point; left lung extremely oedematous throughout, with emboli in the smaller arteries; the stomach was enormously distended with undigested food; at the pyloric end was a crescent-shaped ulcer about three inches long, the middle of the crescent coming just behind the pyloric orifice.

¹ *Trans. of the Assoc. of Phys.*, Vol. III., No. 2.
² *Proc. of the Acad. Sci.*, 1880, p. 476.

The ulcer was deep with sharply defined, clean-cut, indurated border. It had pierced the muscular and serous coats of the stomach and gone into the pancreas, which was adherent to the stomach over the seat of the ulcer; it had also touched the upper edge of the liver; along the base of the ulcer were a few little vessels filled with thrombi; there was no stricture of the pylorus, which freely admitted two and a half fingers; the muscular coat at the pyloric end was hypertrophied; there was thrombosis of the left iliac vein extending as far down as the vein was followed; this thrombus also extended around into the right iliac vein and a short distance down that vessel. Spleen and liver not abnormal.

Remarks. In spite of the youth of this patient, the extreme emaciation and cachectic appearance, with the phlegmasia alba dolens, were suggestive of cancer. The tendency to coagulation of the blood in cachectic patients, especially in the subjects of tuberculosis and cancer, rarely in chlorosis, and quite independently of the puerperal condition, has often been remarked. Trousseau says: "In cases in which the absence of any appreciable tumor made me hesitate as to the nature of a disease of the stomach my doubts were removed, and I knew the disease to be cancerous, when phlegmasia alba dolens appeared in one of the limbs. So great, in my opinion, is the semeiotic value of phlegmasia in the cancerous cachexia, that I regard this phlegmasia as a sign of the cancerous diathesis as certain as sanguinolent effusion into the serous cavities."¹

**INTERSTITIAL NEPHRITIS; PYELITIS; SUPPURATION
OF RETRO-PERITONEAL GLANDS; AUTOPSY.**

Alfred P., a French cook, aged forty-eight, entered the hospital April 27th. He had considered himself perfectly well until within three weeks, when he had had severe headache, dizziness, and vomiting. The vomiting has occurred soon after eating and has followed nearly every meal. A week previous to entrance epistaxis. Patient uses no liquor; temperature 100° F.; pulse 88.

The appearance of the patient is somewhat anæmic but he is in good flesh; no œdema; nothing abnormal heard in chest; urine pale; reaction alkaline; specific gravity, 1007; albumen one half per cent.; sediment contained pus and bladder epithelium with crystals of triple phosphate; no casts found.

April 28. The headache is relieved but he has vomited three times since entrance; no blood in vomitus; epigastric tenderness marked.

April 30th. Has vomited quite frequently; says milk never agreed with him even when diluted with lime-water; the epigastric pain has increased in intensity and spread down upon the abdomen where it is now very severe; he is unable to refer the pain to any particular spot; rubs his hands all over the abdomen but chiefly to the right of umbilicus; slight retraction of left testicle is noticed.

May 1. Vomitus dark-colored; no blood; a spontaneous dejection; suppression of urine since yesterday; says he feels a little better.

May 2. Suppression continues; abdominal pain still severe; is slightly delirious this morning; after sitting up in bed a few minutes he turned on to his side and died almost immediately. After death one and one half ounces of urine were withdrawn from the bladder.

Examination revealed nothing further than on the previous occasion.

Autopsy, twenty-eight hours after death. Pericardium adherent to the left ventricle; valves sufficient; slight atheroma of aorta; considerable hypertrophy of the left ventricle, also of the right; weight of heart twenty ounces; consistency and color good; slight interstitial myocarditis and slight fatty change in the papillary muscles; spleen weighed eight and three fourths ounces; old adhesions to diaphragm and neighboring organs; considerable increase of trabeculae; splenic artery somewhat atheromatous in places; in separating the intestines a small amount of pus was found, which proceeded from the chain of glands at the right of the spine; kidneys both small, cortical portion reduced to a minimum; capsule quite adherent; on being stripped off it left an irregular surface; pelvis of left kidney injected; the mucous surface of both ureters uneven and covered with an abundance of pus which extended down into the bladder.

There was nothing in the lungs or brain to account for the sudden death.

Remarks. This case had been regarded as one of interstitial nephritis, but the increasing abdominal pain, dysuria, and retracted testicle pointed to calculous disease of the pelvis. The suppuration of the retro-peritoneal glands in connection with pyelitis is unusual, and the pain which resulted made the use of morphine, in doses of from one sixteenth to one eighth of a grain, necessary. No ill effects from this drug were apparent.

Recent French writers have reported cases of interstitial nephritis with sudden fatal termination, which appeared to be due to syncope without disease of the cardiac valves.

DIPHTHERIA.

CASE I. Henrietta F., aged seventeen, table girl, entered hospital April 30th. Has had sore throat for three days, constantly growing worse. Marked dysphagia, chills, headache, almost complete aphonia.

Both tonsils much swollen, encroaching considerably on passage of fauces; both tonsils covered with dark brownish membrane over their whole surface. [Patient has been having throat painted.] Temperature 103.2° F. Pulse 120.

She was put at once upon the following treatment (adapted from Guttman):—

R7	Pilocarpin nitrat.	ss.
	Pepsin	ss.
	Acid. hydrochlor. dil.	gtt. iii.
	Aquæ	ad Oss.

Give half an ounce every hour. Immediately after each dose of this medicine to have half an ounce of sherry. Throat atomized every two hours with glycerine and lime water equal parts. An ice-bag about throat. Cracked ice *ad libitum*. To be fed every two hours with liquid food.

May 1st. Right tonsil as before. Left tonsil is more swollen, and the membrane upon it has extended upwards; is not stained as it was yesterday. Patient passed a comfortable night, and the pulse is of good quality. As the ice-bag makes her feel chilly a poultice is substituted. The former medicine is continued, with the addition of twenty minims of chloride of iron every three hours.

May 2d. Right tonsil still enlarged, but membrane has come off, leaving only a spot as large as a split pea at the top. On the left tonsil the membrane is

¹ Trousseau's Clinical Medicine. Sydenham edition. Vol. v., pp. 288, 289.

very extensive, running down as far as can be seen. At the upper half it is black, and there is a well-defined line of demarkation all around it. Patient thinks she has expectorated more in the last two days than before. No sweating. Pulse good.

May 3d. The membrane noted yesterday on left tonsil has much diminished from the periphery on all sides. No new deposit. No diminution in size of tonsil. Odor of breath still remains foul. Some enlargement and tenderness externally at the angle of the jaw. Pulse 90, of good strength. Appetite small; patient comfortable.

Patient is not wakened at night for her medicine; she takes it probably eighteen to twenty times in the twenty-four hours. Each dose contains a little more than one twenty-fourth of a grain of pilocarpin, so that she averages about five sixths of a grain in the twenty-four hours.

May 4th. Right tonsil clear, except for one spot the size of a pin-head. Left tonsil has irregular pieces scattered over it, less in amount than yesterday. At the bottom of the tonsil is the largest piece, about the size of a pea. *r. m.* The membrane on the left tonsil has increased since morning, and extends as far down as can be seen.

May 5th. Left tonsil has cleared off very largely during the night; there remain only a few spots scattered over it. A small deposit on the left side of uvula. Pilocarpin omitted. Sherry reduced to half an ounce every three hours. Iron reduced to three times a day. Poultice about neck omitted. Atomizing continued.

May 6th. Tonsils clear. Atomization omitted. Sherry stopped. Allowed to have her clothes.

May 8th. About her room, much improved.

May 9th. Throat remains clear. Right tonsil still enlarged; patient says it is habitually so. Discharged, *well*.

CASE II. Edward T., aged nineteen, negro, entered the hospital on May 19th, the fifth day of his disease, which had been constantly increasing in severity. He had had all the usual symptoms of diphtheria, including swelling of the glands about the angle of the jaw. No discharge from the nose. Anorexia. Coated tongue. No vomiting. On examination the next morning both tonsils were found much swollen and covered with a dirty, grayish, sloughing membrane, the extent of which was very great. The opposing surfaces of the tonsils met, and with the uvula (which was enlarged and had a white patch) nearly closed the passage of the fauces. The pharynx could hardly be seen. Odor very offensive. Great tenderness at each angle of jaw.

The patient was put on treatment nearly identical with that in the previous case.

May 21st. The membrane has disappeared a little from the sides on the right tonsil, but in a vertical direction is as extensive as before. Left tonsil not much changed. The swelling is less on each side, and the passage of the fauces freer. Membrane seen on pharynx. In the afternoon the pulse remains good. There has been some sweating and somewhat increased expectoration.

May 22d. Uvula very oedematous; no deposit on it. No change in membrane on the tonsils, except that that on the right looks more dirty and sloughing. A thick deposit on the posterior wall of pharynx. Patient says that last evening something burst on left side of throat, discharging chiefly blood. No sign can be

seen to-day of an abscess, on account of the great amount of irregular membranous deposit.

May 23d. Right tonsil much clearer; left still has a good deal of sloughy membrane. At lower part of left tonsil there is a swelling distinct from the rest of the tonsil, about the size of a cherry. Oedema of uvula as before, with a few patches on it. Does not sweat very much. Expectoration very free. On this account, together with a slight weakening of the pulse, the pilocarpin was omitted at night. Other treatment continued.

May 24th. Pulse strong. Glands at the angle of jaw much diminished. Exudation on tonsils and uvula much less. Still considerable swelling of left tonsil and uvula. Patient swallows well, though he reports regurgitation through the nose several times yesterday. Pilocarpin not resumed. Sherry changed to whisky. Poultice to neck omitted.

May 25th. Looks much brighter. Speaks more distinctly. Swallows readily. Swelling diminished. The lower anterior part of left tonsil is quite free, but the remainder is still well covered, and a thin deposit extends forwards upon the anterior palatine arch. Uvula as before, but smaller. Right tonsil has rather a larger area of membrane to-day, but it is thin. All the membrane is smoother and lighter colored than before.

May 26th. There remains behind the uvula at left side a small area of dark-colored, thick, uneven membrane. The rest of the pharynx is clear. Tonsils and uvula have thin white deposits as yesterday. Patient looks bright. Whisky reduced to half an ounce every three hours.

May 28th. Hardly any swelling remains. The parts which had membrane are nearly clear, with only a thin deposit in spots, around which the mucous membrane looks red and healthy.

May 30th. General condition very good. Patches on tonsils and uvula faintly visible.

June 3d. Membrane has wholly gone. Tonsils still look ragged. Patient up and about.

June 6th. Discharged, *well*.

CASES III and IV. Two other mild but undoubted cases of diphtheria were treated by pilocarpin in the same manner.

The first, Mary L., twenty-one, single, entered on the fourth day of the disease, May 26, with membrane upon both tonsils, of which the right was much enlarged. She had herpes labialis, and also three peculiar spots of herpes of size varying from a ten-cent piece to a quarter on the left side of the neck. She was put at once on the treatment. The next day the left tonsil was nearly clear of membrane, though considerably excavated. Right tonsil as before. The pilocarpin was continued without any depressing effect on the pulse till June 1st. The membrane on the right tonsil gradually melted away from the periphery, and later from spots in the centre of the deposit, until June 4th, when it had substantially disappeared, and the patient sat up.

Bella McA., aged nineteen, single, entered with a fading eruption of measles, which had appeared five days before, and with a sore throat of four days' duration. There was at that time a fringe of membrane all about the edge of the uvula, with a thin deposit on the anterior palatine arch. The next day, May 28th, the uvula was more swollen. The deposit had increased, involving the bottom of the left tonsil (size of a pea);

also the right posterior pillar of the fauces, whence it extended a little upon the right tonsil.

In the next two days this membrane diminished, and on June 1st the uvula and tonsils were clear, but there was a patch of the size of a pea on the posterior wall of the pharynx behind the uvula. Two days later the throat was entirely clear. In this case the pilocarpin was given till May 31, then omitted, but resumed the next day on the appearance of membrane in the pharynx, and finally discontinued June 3d, when this last deposit had disappeared.

CASE V. Jennie H., aged four, an inmate of the Pine Street Home, entered the hospital May 16th, with scarlet fever, of which there had been a number of cases in that institution recently. As the eruption faded she failed to improve in a corresponding measure. The temperature remained elevated, and she was restless and fretful, especially at night. The urine revealed nothing abnormal.

May 19th. There was moderate enlargement of the glands at the angle of the jaw, with some tenderness. The throat was reddened, but no membrane could be discovered, and the voice was clear. There began to be a thick and very abundant discharge from the nostrils. Moderate amount of cough. Physical signs in the chest of bronchitis. Vomiting from time to time.

Almost daily examination for the next few days failed to reveal any membrane in the throat. The symptoms continued without amelioration.

May 25th the swelling of the glands had become extreme, and extended backwards behind the sterno-mastoid, especially on the left side. The discharge from the nose still continued abundant and offensive. Inspiration was free, but expiration was interrupted, causing a sound like grunting. Both tonsils were enlarged, but no membrane was visible.

May 26th. For the first time membrane was visible, the posterior pharynx was covered with a dirty deposit; none on the tonsils, which were enlarged and reddened; swelling of neck considerable, especially behind the sterno-mastoid; no difficulty in swallowing; voice clear; tongue slightly coated; pulse 140, and of fair strength.

In addition to the treatment, which had hitherto been mainly expectant, the throat was sprayed with lime-water every two hours. She was given sherry, one half drachm, every hour.

In the next three or four days the glandular swelling subsided; otherwise the symptoms remained unchanged; a good deal of membrane was visible; the odor was not so offensive. The throat was cleansed once or twice a day by placing the child on the side while a stream of water from a fountain syringe was conducted back into the fauces on the upper side of the mouth, and allowed to run out on the lower side. The nares were also syringed. Both of these measures brought away a considerable amount of nasty mucus, but no membrane. The amount of stimulant was varied with the pulse and general condition, at one time being a drachm of sherry every hour.

May 30th. A sharp attack of conjunctivitis came on in each eye, which subsided after two or three days, the eyes being kept well washed with warm water.

June 3d. The child maintains fair strength, though it eats but little; the nasal discharge remains profuse; less membrane is visible than a few days ago.

June 4th. A ragged aperture, as large as a silver five-cent piece, is seen about a quarter inch outside the edge of the right pillar of the fauces; this perfora-

tion extends through, apparently, into the pharynx; the walls of the opening have a sloughy character; the spot now occupied by this orifice in the soft palate yesterday presented no peculiar appearance, so that it seems probable that the perforation occurred from behind forward. The child was now given five drops of the tincture of the chloride of iron every three hours with twenty drops of brandy every hour instead of the sherry. There is no longer any vomiting, but there is reluctance to take any food or medicine or to be disturbed.

June 7th. For the last day or two the patient has looked a little brighter; the pulse is feeble but the child's strength seems fair; the nasal discharge is much diminished; the perforation before noted on the soft palate is now more ragged and sloughy, and there are two small foramina visible outside the left palatine arch, where the mucous membrane looks soft and boggy; air enters the lungs freely, but râles are heard in the front of the chest on each side. The amount of brandy is increased to twenty-five drops every hour.

June 9th. The patient shows great aversion to swallowing, the iron is therefore reduced to five drops three times a day, but she is fed with a teaspoonful of milk every half hour. The perforations before noted on the left side of the soft palate have become blended into one large, ragged opening extending through to the pharynx. There is also an extension of the sloughing process on the right of the uvula.

The urine, which of late has been passed mostly upon the napkin so that no examination has been made for some time, is now retained, requiring the use of the catheter. When first examined the urine was normal, but is now of a specific gravity of 1010, pale, and contains a trace of albumen; the sediment consists of free blood corpuscles, considerable pus, and fine and coarsely granular casts with uric acid crystals. The catheter had to be resorted to a number of times after this.

June 10th. Alimentation by the mouth proving inadequate on account of the child's disinclination to swallow, she was put upon nutritive enemata three times a day in addition to what she could be induced to take by the stomach. The enemata were for the most part well retained.

June 12th. A foul-smelling discharge appears from both ears, which accordingly are syringed with warm water daily. The discharge from the nostrils has nearly ceased, but on giving the douche to the throat some of the water runs out at the nose bringing with it mucus tinged with blood. On inserting the tube to one nostril a large piece of membrane was washed out of the other side. This was the case with nearly every subsequent washing. The fluid as it ran from the mouth contained a large amount of viscid mucus of an offensive odor. The child's strength remains good.

June 14th. The temperature, which has been normal for a few days, is beginning to rise, and the child seems more fretful; pulse 140, of fair strength; a new deposit of membrane is seen on the left tonsil. The pilocarpin treatment was now begun, each dose containing one forty-eighth of a grain; brandy, two drachms, was added to each euema, with half a drachm by mouth every two hours.

June 15th. The spot of membrane seen yesterday has cleared off, but flakes are still removed in washing out the nostrils. The enemata are not well retained. She takes, however, half a drachm of brandy by mouth every hour.

June 16th. This morning she was much weaker, having passed rather a restless night; the pulse was faint; pilocarpin omitted; the discharge from the ears and nose continued tetid. She sank rapidly during the forenoon, and died at one o'clock p. m. Air entered the lungs freely to the last, and the cause of death was apparently exhaustion.

OFFICIAL BULLETINS OF THE PRESIDENT'S CASE.¹

EXECUTIVE MANSION, {

WASHINGTON, D. C., August 22, 1881, 8.30 A. M. {

The President has not vomited since yesterday afternoon, and this morning has twice asked for and received a small quantity of fluid nourishment by the mouth. He slept more quietly during the night, and this morning his general condition is more encouraging than when the last bulletin was issued. Pulse 101, temperature 98.4°, respiration 18.

12.30 p. m. The President has continued this morning to retain liquid nourishment taken by the mouth as well as by enema. There has been no recurrence of the vomiting and no nausea. The parotid swelling is not materially smaller, but continues painless. It has caused for a day or two an annoying accumulation of viscid mucus in the back of the mouth, but this symptom has now much abated. At present his pulse is 104, temperature 98.4°, respiration 18.

6.30 p. m. The President has continued to take nourishment in small quantities at stated intervals during the entire day, and has had no return of nausea or vomiting. The nutrient enemata are also retained. The wound is looking well, and the work of repair is going on in all portions exposed to view. The pus discharged is healthy. At present his pulse is 110, temperature 100.1°, respiration 19.

EXECUTIVE MANSION, {

WASHINGTON, D. C., August 23, 1881, 8.30 A. M. {

The President slept the greater part of the night, but awoke at frequent intervals. He has taken since last evening a larger quantity of liquid food by the mouth than in the corresponding hours of any day during the past week. The use of nutrient enemata is continued at longer intervals. The parotid swelling is unchanged. Pulse 100, temperature 98.4°, respiration 18.

12.30 p. m. The President continues to take by the mouth and retain an increased quantity of liquid food. At the morning dressing the wound looked well, and the pus was of a healthy character. The mucus accumulations in the back of the mouth on account of the parotid swelling are less viscid, and now give but little trouble. At present his pulse is 104, temperature 99.2°, respiration 18.

6.30 p. m. The President has continued to take liquid food by the mouth at regular intervals during the day, and has had no recurrence of gastric disorder. The parotid swelling remains unchanged. In other respects the symptoms show some improvement over his condition yesterday afternoon. Pulse 104, temperature 99.2°, respiration 19.

To LOWELL, Minister, London:—

The President's condition is more encouraging than it was at this time last night. During the last twenty-four hours he has swallowed ten ounces extract of beef and eighteen ounces of milk, retaining and digesting both. He has twice asked for food, which he has not done before for several days. Pulse and temperature are both somewhat lower. The swelling of the parotid gland has not specially changed. Its long continuance at present stage increases the fear of suppuration. At this hour (11 o'clock) the physicians report that the President has rested quietly the entire evening.

BLAINE, Secretary.

WASHINGTON, D. C., August 24, 1881.

To DR. D. HAYES AGNEW, Philadelphia, Pa.:—

Subject of removal of President from the White House is being seriously considered. We desire your immediate presence. Answer.

D. W. BLISS.

8.30 p. m. The President passed a very good night, awaking at longer intervals than during several nights past. He continued to take liquid food by the mouth with more relish, and in such quantity that the enema trial was suspended for the present. No change has yet been observed in the parotid swelling. The other symptoms are quite as favorable as yesterday. Pulse 100, temperature 98.5°, respiration 17.

12.30 p. m. The President continues to take liquid food by

the mouth as reported in the last bulletin. His temperature has risen slightly since that time. In other respects his condition is about the same. Pulse 104, temperature 99.2°, respiration 17.

6.30 p. m. Shortly after the noon bulletin was issued an incision was made into the swelling on the right side of the President's face for the purpose of relieving the tension of the swollen parotid gland, and of giving vent to pus, a small quantity of which was evacuated. He has taken a larger quantity of liquid food by the mouth to-day than yesterday, and has been entirely free from nausea. His temperature this afternoon is however, higher than yesterday at the same hour, and his pulse somewhat more frequent. Pulse 108, temperature 100.7°, respiration 19.

To LOWELL, Minister, London:—

The President has not gained to-day. He has had a higher fever than is usual with his febrile rise. In the afternoon an incision was made in the swollen parotid gland by Dr. Hamilton. The flow of pus therefrom was small. The one favorable symptom of his swallowing liquid food with apparent relish, and digestion has continued, but the general feeling up to midnight is one of increased anxiety.

BLAINE, Secretary.

EXECUTIVE MANSION, {

WASHINGTON, D. C., August 25, 1881, 8.30 A. M. {

The President slept most of the night. He has taken liquid food by the mouth at stated intervals and in sufficient quantity, so that the enemata have not been renewed. No modification of the parotid swelling has yet been observed. His general condition is much the same as at this time yesterday. Pulse 106, temperature 98.5°, respiration 18.

9.15 A. M. The subject of the removal of the President from Washington at the present time was earnestly considered by us last night and again this morning. After mature deliberation the conclusion was arrived at by the majority that it would not now be prudent, although all agree that it will be very desirable at the earliest time at which his condition may warrant it. We are, moreover, unanimously of the opinion that at no time since the injury has the President exhibited any symptoms of malaria.

12.30 p. m. Since the issue of this morning's bulletin a rise in the President's temperature similar to that which occurred yesterday morning has been observed. His pulse is somewhat more frequent. From the incision in the parotid swelling a few drops of pus were discharged this morning. The size of the swelling has not diminished. In other respects his condition has not perceptibly changed. Pulse 112, temperature 99.2°, respiration 19.

6.30 p. m. There has been little change in the President's condition since the noon bulletin was issued. The frequency of his pulse is now the same as then. His temperature has risen somewhat, but is not so high as yesterday evening. There has been a slight discharge of pus during the day from the incision in the parotid swelling, but it is not diminished in size. No unfavorable change has been observed in the condition of the wound. He has taken by the mouth a sufficient supply of liquid food. At present his pulse is 112, temperature 99.8°, respiration 19.

To LOWELL, Minister, London:—

The President has lost ground to-day. Some of his symptoms this afternoon and evening are of the gravest character. The condition of the swollen gland and of the pulse and temperature suggest serious and alarming complications. His mind at intervals has been somewhat beclouded and wandering. His strength fails, but he still swallows liquid food of a nourishing character, and apparently digests it. On this one fact rests the hope that is still left of a reaction.

BLAINE, Secretary.

EXECUTIVE MANSION, {

WASHINGTON, D. C., August 26, 1881, 8.30 A. M. {

The President slept most of the night, awakening at intervals of half an hour to an hour. On first awakening there was, as there has been for several nights past, some mental confusion, which disappeared when he was fully roused, and occasionally he muttered in his sleep. These symptoms have abated this morning, as on previous days. At present his temperature is slightly above the normal, and his pulse a little more frequent than yesterday morning. Pulse 108, temperature 99.1°, respiration 17.

12.30 p. m. At the morning dressing of the President it was observed that pus from the parotid swelling had found its way spontaneously into his right external auditory meatus, through which it was discharging. Some pus was also discharging through the incision made into the swelling. His wound looks as well as it has done for some time past. His pulse and tem-

¹ Continued from page 299.

perature are at present higher than at the corresponding hour for some days. He continues to take, by the mouth, the liquid food prescribed; nevertheless we regard his condition as critical. Pulse 118, temperature 100°, respiration 18.

6.30 p. m. The President's condition has not changed materially since the last bulletin was issued. He continues to take by the mouth the liquid food prescribed, and occasionally asks for it. Since yesterday forenoon, commencing at 11.30 o'clock, the enemata have again been given at regular intervals, as a means of administering stimulants as well as nutrition. They are retained without trouble. At present his pulse is 116, temperature 99.9°, respiration 18.

To LOWELL, Minister, London: —

While the President has made no gain to-day his loss of ground has been less in the judgment of his physicians than was feared last night. In this aspect there is a slight feeling of encouragement, or at least a ray of hope. The adverse symptoms are still manifest, and the one favorable indication of swallowing and digesting liquid food continues. Two or three times during the day he has asked for nourishment. He has spoken intelligently and voluntarily, and throughout the day his mind has been less affected than yesterday. The expected relief to the parotid swelling from the discharge through the ear has not been realized. The situation is one of great gravity and danger.

BLAINE, Secretary.

EXECUTIVE MANSION, }

WASHINGTON, D. C., August 27, 1881, 8.30 A. M. }

The President slept from half an hour to an hour or more at a time through the night. He continues to retain the liquid food administered by the mouth and the stimulating enemata, nevertheless his pulse has been more frequent since midnight, and he is evidently feebler this morning than yesterday. Pulse 120, temperature 98.4°, respiration 22.

12.30 p. m. There has been no improvement in the President's condition since the last bulletin was issued. He continues to retain the liquid food administered by the mouth as well as the enemata. At the morning dressing the parotid swelling appeared about the same as yesterday. No material change has been observed in the wound since morning. The temperature has risen about a degree, and the pulse has fluctuated somewhat. At present, pulse 120, temperature 99.6°, respiration 22.

6.30 p. m. The President's symptoms show slight amelioration this afternoon. His pulse is somewhat less frequent and his temperature lower. Moreover the mental disturbance described in yesterday morning's bulletin has disappeared. The parotid swelling has discharged a little pus by the opening spontaneously formed into the ear, as well as by the incision made, but is not perceptibly smaller. The liquid food given by the mouth and the enemata continue to be retained. Pulse 114, temperature 99°, respiration 22.

To LOWELL, Minister, London: —

There is a somewhat more hopeful feeling to-night in regard to the President. The regular evening bulletin was more favorable, and the good indications have continued. His pulse is lower, being now 114. His mind is entirely clear. He has shown positive appetite, asking for milk toast, a small quantity of which he was permitted to eat. This is the first time for many days that he has swallowed anything but liquid food. A slight increase in his respiration is the only adverse symptom reported at this hour — 10.30 p. m.

BLAINE, Secretary.

EXECUTIVE MANSION, }

WASHINGTON, D. C., August 28, 1881, 8.30 A. M. }

The amelioration of the President's symptoms announced in last evening's bulletin continued during the night, and since midnight some further improvement has been observed, the pulse progressively diminishing in frequency. The stomach has continued to retain the liquid nourishment administered, and last night he asked for and ate a small quantity of milk toast. Stimulating and nutrient enemata continue to be retained. There has been no mental disturbance during the night or this morning. At present his pulse is 100, temperature 99.4°, respiration 17.

12.30 p. m. At the morning dressing of the President several yellowish points were observed just below the ear over the swollen parotid, and an incision being made about a teaspoonful of healthy-looking pus escaped. There was also some discharge of pus through the two openings into the ear and incisions mentioned in previous bulletins. The wound looks rather less indolent than it has been doing for several days past. Since the morning bulletin there has been some rise of temperature, but little increase in the frequency of pulse, and in other respects no material change has occurred. Pulse 104, temperature 99.5°, respiration 18.

6.30 p. m. The improvement in the President's condition declared yesterday afternoon is still maintained. He continues to take willingly the liquid food given by the mouth and is apparently digesting it. The stimulants and nutrient given by enemata are also retained. At the evening dressing an increased quantity of healthy-looking pus was discharged from the suppurating parotid. The appearance of the wound has not perceptibly changed since the morning dressing. But little rise in temperature or pulse has taken place since noon, and the pulse is perceptibly stronger than at this time yesterday. Pulse 110, temperature 99.7°, respiration 20.

To LOWELL, Minister, London: —

The favorable indications in the President's case have continued since the dispatch of last night. The respiration has grown better, and at this hour (2 p. m.) is nearly normal. The condition of the swollen parotid has visibly improved. A slight increase of fever is observable, but was not unexpected. His mind continues clear. The possibilities of recovery in the judgment of his surgeons have increased and are increasing.

(Signed)

BLAINE.

To LOWELL, Minister, London: —

The condition of the President at 10 o'clock continues as favorable as could be expected. Within the past thirty hours his improvement has given great encouragement to the attending surgeons. He swallows an adequate supply of liquid food, the parotid swelling discharges freely and gives promise of marked improvement. His mind is perfectly clear. He has perhaps a little more fever than was anticipated and his respiration is somewhat above normal. The general feeling is one of hopefulness. Two or three days more of improvement will be needed to inspire confidence.

BLAINE, Secretary.

EXECUTIVE MANSION, }

WASHINGTON, D. C., August 29, 1881, 8.30 A. M. }

The President's symptoms this morning are as favorable as yesterday at the same hour. He slept, awakening at intervals, the greater part of the night. At these intervals he took and retained the liquid nourishment administered. His mind continues perfectly clear. Pulse 100, temperature 98.5°, respiration 17.

12.30 p. m. At the morning dressing of the President's wound an additional point of supuration was recognized in his swollen face, which, being incised, gave exit to some healthy-looking pus. Two other openings on the exterior of the swelling are likewise discharging, but though less tense, the tumefaction (swelling) has not materially diminished in size. Nothing new has been observed in the condition of the wound. The usual daily rise of temperature has not materially changed since morning. Pulse 106, temperature 98.6°, respiration 18.

6.30 p. m. The daily rise of the President's temperature began later this afternoon than yesterday, but rose eight tenths of a degree higher. The frequency of his pulse is now the same as at this hour yesterday. He has taken willingly the liquid food prescribed during the day, and had besides, during the morning, a small piece of milk toast. At the evening dressing a pretty free discharge of healthy pus took place from the parotid swelling, which is perceptibly diminishing in size. The wound manifests no material change. Pulse 110, temperature 100.5°, respiration 18.

To LOWELL, Minister, London: —

The President had a good night and is having a good day. At this hour (2 p. m.) his pulse is 103, showing a decrease from the forenoon. For many days past the pulse has shown a decided increase by this time in the afternoon. His respiration is normal. All other symptoms are reported by his surgeons to be favorable.

BLAINE, Secretary.

To LOWELL, Minister, London: —

At 10.30 to-night the general condition of the President is favorable. Late in the afternoon his pulse rose to 112 and his temperature to 100°, both a little higher than the surgeons expected. The pulse has now fallen to 103, and the fever is subsiding. The parotid swelling is steadily improving, and is at last diminishing in size. Apprehensions of serious blood poisoning grow less every hour.

BLAINE, Secretary.

EXECUTIVE MANSION, }

WASHINGTON, D. C., August 30, 1881, 8.30 A. M. }

The President slept the greater part of the night, awakening at intervals, and retaining the liquid nourishment administered. His general condition this morning is about the same as at the same hour yesterday. Pulse 102, temperature 98.5°, respiration 18.

12.30 p. m. At the morning dressing another small incision was made in the lower part of the swelling on the right side of

the President's face, which was followed by a free discharge of healthy-looking pus. A similar discharge took place through the other openings. The swelling is perceptibly smaller and looks better. The wound remains in an unchanged condition. There has been little rise of temperature since morning, but the pulse is more frequent. In other respects the condition is about the same. Pulse 116, temperature 98.9°, respiration 18.

6.30 P. M. The President has passed comfortably through the day. He has taken the usual amount of nourishment by the mouth, with stimulating enemata at stated periods. His rise of temperature this afternoon is a degree less than yesterday at the same time, and his pulse is less frequent than at noon to-day. The parotid swelling has been discharging more freely and is continuing to diminish in size. Pulse 109, temperature 99.5°, respiration 18.

To LOWELL, Minister, London:—

The President's condition has not materially changed since my last dispatch. Another incision was made this morning in the parotid gland with very satisfactory results. Pus flows freely and the swelling grows less. The pulse at this hour (2 P. M.) is lower than during the forenoon, as yesterday. But on both days it is higher than his other good symptoms would seem to warrant. It is now 110; at noon it was 116.

BLAINE, Secretary.

EXECUTIVE MANSION, 10.30 P. M.

To LOWELL, Minister, London:—

The President, if not rapidly advancing, is at least holding his own. His fever is less than last night and his swollen gland steadily improves. His pulse continues rather high, running this evening from 110 to 114. Perhaps the best indication in the case is that the President himself feels better, and his mind being now perfectly clear he readily compares one day's progress with another.

BLAINE, Secretary.

EXECUTIVE MANSION,

WASHINGTON, D. C., August 31, 1881, 8.30 A. M. }

The President has passed a tranquil night, and this morning his condition is quite as favorable as yesterday at the same hour. Pulse 109, temperature 98.4°, respiration 18.

12.30 P. M. At the dressing of the President this morning the parotid swelling was found to be discharging freely. It looks well, and has materially diminished in size. The wound remains in about the same state. His general condition is evidently more favorable than at this hour yesterday. Pulse 95, temperature 98.4°, respiration 17.

6.30 P. M. The President has passed a better day than for some time past. He has taken his food with increased relish, and the afternoon rise of temperature did not occur. At the evening dressing the fluid used to wash out the parotid abscess found its way into the mouth, which it did not do this morning, showing that an opening into the mouth had spontaneously occurred. The abscess is discharging freely and the swelling continues to diminish. There is some increase in the discharge of pus from the wound. Pulse 109, temperature 98.6°, respiration 18.

To LOWELL, Minister, London:—

The President has had less fever this evening than upon any previous evening since he was wounded. His temperature at 6 o'clock was normal. The entire day has been most encouraging in all his symptoms. Hereafter I shall send but one report daily.

BLAINE, Secretary.

EXECUTIVE MANSION,

WASHINGTON, D. C., September 1, 1881, 8.30 A. M. }

Towards 9 o'clock last evening the President had some feverishness, and his pulse ranged from 108 to 116. This condition, which was unaccompanied by rigors or sweating, had subsided by midnight, and did not interfere with his sleep. He had, on the whole, a good night, and this morning his condition is fully as favorable as yesterday at the same hour. Pulse 100, temperature 98.1°, respiration 17.

12.30 P. M. At the morning dressing of the President the abscess of the parotid was found to be discharging freely. It looks well and continues to diminish in size. The state of the wound remains the same. His general condition is not materially different from what it was at this hour yesterday, except that the pulse is somewhat more frequent. Pulse 108, temperature 98.6°, respiration 18.

6.30 P. M. The condition of the President has not materially changed since my last bulletin, except that there has been a noticeable rise of temperature this afternoon. It having been reported in my last bulletin that the morning's bulletin had been misinterpreted, we would state that the President has had

no rigors for several weeks. At present his pulse is 108, temperature 99.8°, respiration 18.

To LOWELL, Minister, London:—

The President continues to do well in his eating and digestion, and the swollen gland steadily improves; but in the past twenty-four hours he has made no substantial progress in his general condition. In the judgment of his physicians he still holds the ground gained on Sunday and Monday last. His pulse and temperature to-day have shown marked increase over the record of yesterday. The weather has been exceedingly warm and sultry, and this may account in part for the adverse changes noted. Even in the September climate of Washington such an oppressive day as this has been is rare.

BLAINE, Secretary.

EXECUTIVE MANSION,

WASHINGTON, D. C., September 2, 1881, 8.30 A. M. }

The President slept well during the night, and this morning his condition is in all respects as favorable as yesterday at the same hour. Pulse 100, temperature 98.4°, respiration 17.

12.30 P. M. The President's condition has not materially changed since the morning bulletin was issued. Pulse 100, temperature 98.7°, respiration 18.

6.30 P. M. The President has passed a comfortable day, and this evening appears better than for some days past. He has taken a larger proportion of nutriment by the mouth, and manifested greater relish for it. His pulse shows some improvement as regards frequency and strength. The parotid abscess continues to improve. The wound shows as yet little change. This evening his pulse is 104, temperature 99.4°, respiration 19.

EXECUTIVE MANSION,

WASHINGTON, D. C., September 3, 8.30 A. M. }

The President was somewhat more restless than usual during the early part of the night, but slept better after 1 A. M. This morning his general condition does not differ materially from what it was at the same hour yesterday, except that there is a slight increase in the frequency of the pulse. Pulse 104, temperature 98.6°, respiration 18.

12.30. The President's condition has not materially changed since the morning bulletin was issued. Pulse 104, temperature 98.4°, respiration 18.

6 P. M. The President has done well during the day, and has taken, with some relish, a sufficient quantity of nutriment. The parotid swelling continues to discharge freely and to diminish in size. The wound shows no material change. Altogether, his general condition exhibits some improvement over yesterday. Pulse 102, temperature 99.6°, respiration 16.

To LOWELL, Minister, London:—

In the judgment of the surgeons, the President has gained to-day. The change is not great, but it is in the right direction and against the adverse influence of a very oppressive day. His appetite is improving, and his pulse, temperature, and respiration have all been better than might have been expected in such excessive heat. The President will probably be removed to Long Branch early next week to escape the malarious influence of the Washington climate at this season.

BLAINE, Secretary.

EXECUTIVE MANSION,

WASHINGTON, D. C., September 4, 1881, 8.30 A. M. }

The President vomited once late last evening and once about an hour after midnight. Notwithstanding this disturbance he slept well most of the night, and this morning has taken food by the mouth without nausea, and has retained it. His pulse is somewhat more frequent, but in other respects his condition is about the same as at this hour yesterday. Pulse 108, temperature 98.4°, respiration 18.

12.30 P. M. The President's condition has not changed materially since the last bulletin was issued, and there has been no further gastric disturbance. Pulse 106, temperature 98.4°, respiration 18.

6.30 P. M. The President has passed a comfortable day. He has taken his food with some relish, and had no return of the irritability of the stomach reported in the morning's bulletin. The parotid swelling continues to improve, and is now so far reduced that the contour of his face is restored. The wound shows no material change. The rise of temperature this evening has been very slight, but his pulse was more frequent throughout the day than yesterday, or the day before, and he showed more fatigue after the dressing. Pulse 110, temperature 99°, respiration 18.

To LOWELL, Minister, London:—

Last night the President did not rest well, and twice during the night his stomach was so disturbed that he vomited. Dur-

ing the day he has been better, and has swallowed his usual quantity of food and retained it. His pulse, however, has been higher than for the two preceding days. His surgeons do not think he has lost ground, but he certainly has not gained since last night's dispatch. At this hour, 10.30, he is quietly sleeping.

BLAINE, *Secretary*.

EXECUTIVE MANSION, }

WASHINGTON, D. C., September 5, 1881, 8.30 A. M. }

The President was somewhat restless during the early part of the night, but slept well after midnight. He has taken by the mouth and retained the nutriment prescribed. This morning his pulse is less frequent than yesterday. His temperature is a degree above normal. Pulse 102, temperature 99.5°, respiration 18.

12.30 P. M. The President's condition has not changed materially since the last bulletin was issued, except there is some increase in the frequency of the pulse. He has taken with some relish the nourishment administered by the mouth, and had no return of gastric irritability. Pulse 114, temperature 99.5°, respiration 18.

6.30 P. M. No material change has taken place in the condition of the President since morning. The parotid abscess continues to improve, and the wound remains about the same. The pulse is somewhat less frequent than at noon. At present it is 108, temperature 99.8°, respiration 18. Should no untoward symptoms prevent, it is hoped to remove the President to Long Branch to-morrow.

TO LOWELL, *Minister, London* :—

This has been the hottest day of the season and the heat has told upon the President. His pulse and temperature have been higher than for several days past. In other respects there has been no special change, either favorable or adverse. It is expected that he will be removed to Long Branch to-morrow. It is hoped that the sea air will strengthen him.

BLAINE, *Secretary*.

LONG BRANCH, N. J., September 6, 1881, 6.30 P. M.

Since the last bulletin was issued the President has been moved from Washington to Long Branch. He was more restless than usual last night, being evidently somewhat excited by anticipations of the journey. This morning at 5.30 his pulse was 118, temperature 99.8°, respiration 18. We left Washington with the President at 6.30 A. M. Owing to the admirable arrangements made by the Pennsylvania Railroad Company, and to the ingeniously-arranged bed designed by Mr. T. N. Ely, the fatigue incident to the transportation was reduced to a minimum. Nevertheless, as was anticipated, some signs of the disturbance produced by the journey have been exhibited since his arrival by rise of temperature and increased frequency of pulse. At present his pulse is 124, temperature 101.6°, respiration 18.

TO LOWELL, *Minister, London* :—

The President left Washington at half-past six this morning and reached Long Branch at twenty minutes past one. He seemed to bear the journey well, though the heat was very oppressive. After his arrival he was for several hours restless, showed signs of fatigue, and complained that his back had a bruised feeling. His pulse rose to 124 and his temperature to 101.1. At this hour (10.30) he is sleeping, and his fever is abating. His surgeons regard his symptoms as the necessary result of the journey, and expect a favorable change within the next two days. The fever is in part attributed to the excitement he felt at the prospect of coming. He earnestly desired to leave the White House, and his weary eyes welcomed the sight of the sea. The developments of the next sixty hours are awaited with solicitude.

BLAINE, *Secretary*.

LONG BRANCH, N. J., September 7, 1881, 9 A. M.

The President slept the greater part of the night, awakening, however, as often as it was necessary to give nourishment, which he took very well. The fever reported in last evening's bulletin had subsided by 11 P. M. This morning his temperature is normal, and he appears to have quite recovered from the fatigue of yesterday's journey. At the morning dressing the parotid abscess was found to be doing well. The visible parts of the wound looked somewhat better. Pulse 106, temperature 98.4°, respiration 18. The next bulletin will be issued at 6 o'clock this evening.

6 P. M. Notwithstanding the exceptional heat of the weather, the thermometer in his bedroom rising to 94 at 3.30 this afternoon, there was a breeze most of the day, so the President was comparatively comfortable. He has taken his nourishment regularly, and has slept at intervals during the day. At 12.15 P. M. his pulse was 114, temperature 98.4°, respiration 18. Since then there has been some rise of temperature, though less than yes-

terday, and the pulse has somewhat diminished in frequency. At the evening dressing the appearance of the wound was favorable. At present his pulse is 108, temperature 101°, respiration 18.

TO LOWELL, *Minister, London* :—

The President has not gained in the last twenty-four hours. His fever increased considerably during the afternoon, his temperature reaching 101°. He takes food without nausea, but without appetite, and has not improved in strength. The day is said to be as hot as was ever known at Long Branch. Cooler weather is reported from the West, and lower temperature, with relief to the President, is hoped for to-morrow.

BLAINE, *Secretary*.

LONG BRANCH, N. J., September 8, 1881, 8 A. M.

At the morning examination, made at 8 o'clock, the President's pulse was 104, temperature 98.7°, respiration 18. He was restless and wakeful during the early part of the night, but after 12, midnight, slept well until morning. His general condition appears more encouraging.

6.30 P. M. At 12 M. to-day the President's temperature was 98.4°, pulse 94, respiration 17. At the evening dressing, 5.30 P. M., his temperature was 99.1°, pulse 100, respiration 18. He has taken a liberal amount of food, both solid and fluid, with apparent relish. By special request of the President, it has been made our duty to say in this public way to Surgeon-General J. K. Barnes, Surgeon J. J. Woodward, and Dr. Robert Reyburn, that in dispensing with their services as his medical attendants he was actuated only by a wish to relieve them of labor and responsibility which in his improved condition he could no longer properly impose upon them. Both the President and Mrs. Garfield desire to express to these gentlemen, personally, and in the same public manner, their high appreciation of the great skill and discretion which they have so constantly exercised as associate counsel in the management of his case up to the present time.

LONG BRANCH, N. J., September 9, 1881, 8.30 A. M.

At the examination of the President at 8 A. M. the temperature was 98.5°, pulse 100, respiration 17. The conditions of the parotid gland and wound are improving. He was somewhat wakeful in the night, but not restless, and slept sufficiently. The enemata and stimulants have been suspended during the past thirty-six hours. On the whole the past twenty-four hours give evidence of favorable progress.

6 P. M. At the examination of the President at 12 M. to-day the temperature was 98.4°, pulse 100, respiration 17. At the evening dressing at 5.30 P. M. the temperature was 98.8°, pulse 100, respiration 18. It is believed, without referring to the records, that this is the first day since the development of the traumatic fever that the temperature, pulse, and respiration have been so nearly normal and uniform throughout the entire day.

TO LOWELL, *Minister, London* :—

The medical reports are all favorable to-day—morning, noon, and night. The President has not for many weeks done so well for so many consecutive hours. He has had very little fever. His respiration has been normal and his pulse has not exceeded 100. He slept without opiate and gained strength without stimulant. His nights are not so restful as could be desired, but in the twenty-four hours he gets sufficient sleep. The weather, though not excessively warm, continues sultry and oppressive. Much is hoped from the clear, bracing air which may be expected here at this season.

BLAINE, *Secretary*.

LONG BRANCH, N. J., September 10, 1881.

At the examination of the President at 8.30 this morning, the temperature was 99.4°, pulse 104, respiration 18. He slept well during the night, awaking only at intervals of one half to one hour. There is a perceptible increase of strength, with an improved condition of the digestive apparatus. The tumefaction of the parotid has entirely disappeared, and the suppuration has greatly diminished. The wound continues to improve, and presents a more healthy appearance.

In reference to the retirement of Surgeon-General Barnes, Surgeon J. J. Woodward, and Dr. Robert Reyburn from the corps of physicians in attendance on President Garfield, which, if allowed to pass unnoticed, is calculated to reflect injuriously on the professional character of these gentlemen, it is stated that on the Saturday or Sunday preceding the removal of the President to Long Branch, the President communicated to Dr. Bliss the wish that Drs. Barnes, Woodward, and Reyburn should not accompany him there; that, on this information being conveyed to the gentlemen, the latter were reluctant to be left, and, in order to adjust the matter, they appealed to Dr. Agnew,

who effected a compromise by which Drs. Barnes, Woodward, and Reyburn were to accompany the President from Washington to Long Branch, and that their connection with the case should cease. In answer to these statements, I beg leave to say that I am entirely ignorant of any such transaction, and certainly never was asked to act as a referee in the settlement of any question of the kind. No one knowing the high personal and professional character of the three gentlemen in question would for one moment do them the great injustice to believe that they would desire to continue their connection with a case after receiving the information purported to have been made.

(Signed) D. HAYES AGNEW.

LONG BRANCH, N. J., September 10, 1881, 8.30 A. M.

There is a perceptible increase of strength, with an improved condition of the digestive apparatus. The tumefaction of the parotid has entirely disappeared, and the suppuration has greatly diminished. The wound continues to improve, and presents a more healthy appearance. Pulse 104, temperature 99.4°, respiration 18.

6 P. M. At the examination of the President at 12 to-day his pulse was 100, temperature 98.5°, respiration 18. At 5.30 this evening his pulse was 100, temperature 98.7°, respiration 18. The President has taken a greater amount of liquid, with some solid food, and with more relish than for several days. His general condition is quite as favorable as yesterday.

To LOWELL, Minister, London:—

After dispatch of last night the President had considerable increase of fever. Indeed, a rise of pulse and temperature every night has become a significant feature in his case. Through the day, and especially this afternoon, he has grown more comfortable. A cold easterly storm has prevailed since early morning without evil effect thus far on his condition. Secretary Windom had a brief interview with the President at noon. He found him much reduced in strength, but clear in his mind. He asked the Secretary about the success of the refunding of the public debt.

(Signed) BLAINE, Secretary.

LONG BRANCH, September 11, 1881, 9 A. M.

At the examination of the President at 8.30 A. M. his temperature was 99.8°, pulse 104, respiration 19. He was more restless, and the febrile rise was later than on the preceding night. He continues to take sufficient nourishment without gastric disturbance.

6 P. M. The President has passed a quiet day, although the temperature has been somewhat higher and his pulse more frequent than during the previous twenty-four hours. At the evening dressing quite a large slough of connective tissue was removed from the region of the parotid gland. He continues to take a sufficient quantity of nourishment, and enjoys it. At the noon examination the temperature was 100°, pulse 110, respiration 20. At the evening dressing his temperature was 100.6°, pulse 110, respiration 20.

To LOWELL, Minister, London:—

The President had an increase of fever last night, and was very restless until 5 o'clock A. M. During the day he has been somewhat better, but his pulse, temperature, and respiration have been higher for the entire twenty-four hours than on any preceding day since he reached Long Branch. His other symptoms are not reassuring, and his general condition gives rise to anxiety.

BLAINE, Secretary.

LONG BRANCH, September 12, 1881, 9 A. M.

The President passed an unusually good night, his sleep being uninterrupted, except occasionally, to enable him to take nourishment. The suppuration from the parotid gland has almost entirely ceased; the opening from which the pus discharged is rapidly healing. The cough is less, and the expectoration materially diminished. The temperature is 98.4°, pulse 100, respiration 18.

6 P. M. The President has experienced since the issue of the morning bulletin further amelioration of symptoms. He has been able to take an ample amount of food without discomfort, and has had several refreshing naps. At the noon examination the temperature was 99.2°, pulse 106, respiration 20. At 5.30 P. M. the temperature was 98.6°, pulse 100, respiration 18.

To LOWELL, Minister, London:—

The President slept well last night and his condition to-day is not so comfortable and more favorable. During my absence for a short time Dr. Agnew and Dr. Hamilton will send you a daily report.

BLAINE, Secretary.

To LOWELL, Minister, London:—

In the absence of Mr. Blain the attending physicians have requested me to inform you of the President's condition. He

has during the day eaten sufficient food with relish, and has enjoyed at intervals refreshing sleep. His wound and the incisions made by the surgeons all look better, the parotid gland has ceased suppuration, and may be considered as substantially well. He has exhibited more than his usual cheerfulness of spirits. His temperature and respiration are now normal, and his pulse is less frequent and firmer than at the same hour last evening. Notwithstanding these favorable symptoms, the condition of the lower part of the right lung will continue to be a source of anxiety for some days to come.

MACVEAGH.

LONG BRANCH, N. J., September 13, 1881, 8.30 A. M.

At the examination of the President at 8 A. M. to-day his temperature was 99.4°, pulse 100, respiration 20. He passed a comfortable night, sleeping most of the time, and on the whole his condition this morning is encouraging, and gives promise of a good day.

6 P. M. At the examination of the President at 12 M. to-day the temperature was 98.8°, pulse 100, respiration 20. At the evening dressing, at 5.30 P. M., temperature was 98.4°, pulse 100, respiration 20. The President was placed in a semi-recumbent position upon an invalid chair at 11 A. M., and remained one half hour without fatigue or discomfort. The wounds are making the usual favorable progress and his general condition is reassuring.

To LOWELL, Minister, London:—

There has been no material change in the President's condition during the last twenty-four hours. He was moved, at his own request, this forenoon from his bed to an extension chair, in which he remained for half an hour, and he has been less inclined to drowsiness during the day than usual. The weather is now very favorable, and the physicians think they discover signs of a slight improvement in his symptoms. They expect him to pass a very comfortable night.

MACVEAGH.

LONG BRANCH, N. J., September 14, 9 A. M.

At the examination of the President at 8.30 this morning, the temperature was 98.4°, pulse 100, respiration 19. He passed the night comfortably, sleeping sufficiently. He is bright and cheerful this morning, and has taken fruits and his first meal for the day with relish.

At the examination of the President at 12 M., to-day, his temperature was 98.8°, pulse 104, respiration 20. At the evening dressing at 5.30 P. M. the temperature was 99.2°, pulse 112, respiration 21. The President was placed on the invalid chair in a semi-recumbent position about 12 M., and remained one hour and a half, sleeping a part of the time. He was not fatigued by the transfer or change of position, and his general condition this evening is as favorable as usual, notwithstanding a slight febrile rise.

To LOWELL, Minister, London:—

There is an increase, this evening, in the President's temperature, pulse, and respiration, but it is so slight as not necessarily to indicate that the condition of the blood is producing any new complications. The trouble in the right lung is not increasing, and is causing him less annoyance. He has taken adequate nourishment, and his sleep has been natural and refreshing, so that, if he has gained nothing, he has, probably, lost nothing during the day.

MACVEAGH.

LONG BRANCH, N. J., September 15, 9 A. M.

At the morning dressing, at 8.30 to-day, the President's temperature was 98.4°, pulse 100, respiration 20. He passed the night comfortably, sleeping until 3 A. M., when he was awake for a period of two hours, during which time the pulse rose to 120, but without the marked elevation of temperature which has characterized the febrile disturbance heretofore. After this time he slept until morning. More nourishment was given during the night than for several nights past. In reviewing the case of the President since his arrival at Long Branch, it may be said that, in spite of the various septic accidents which have for several weeks and do still complicate his case, he has certainly not retrograded, but, on the contrary, has made some progress towards convalescence.

5.30. The President has passed a quiet day, sleeping a little; has coughed occasionally, the expectoration being less purulent. A greater variety of nourishment has been taken without discomfort. He was placed upon the invalid chair, and remained forty-five minutes in a position a little more elevated than on previous occasions. At 12 M. to-day his temperature was 98.5°, pulse 102, respiration 21. At the evening dressing, 5.30 o'clock, the temperature was 99.2°, pulse 104, respiration 21.

To LOWELL, Minister, London:—

The President's condition does not appear to have undergone any material change to-day, all his symptoms continuing sub-

stantially the same as yesterday, except that the expectoration from the right lung has been rather less difficult and less profuse. He is still very weak, and this weakness is due to the condition of the blood. While it continues grave anxiety must also continue.

MACVEAGH.

LONG BRANCH, N. J., September 16, 1881, 9 A. M.

At the examination of the President at 8.30 this morning the temperature was 98.6°, pulse 104, respiration 21. The febrile rise during the night was not as pronounced as it usually has been. There was at times considerable acceleration of pulse. He, however, slept comparatively well, and took stimulants and nourishment as directed. The cough was somewhat more troublesome during the first part of the night, and the expectoration rather more purulent. The discharge from the wound is less abundant, and not quite as healthy in appearance. The pulse, however, has more volume, and his general condition does not seem to have materially changed in any respect.

6 P. M. At the examination of the President at noon to-day, the temperature was 99.8°, pulse 116, respiration 21. At the evening dressing, at 5.30 P. M., the temperature was 98.6°, pulse 104, respiration 22. A slight febrile rise occurred at 11 A. M., and had entirely subsided at 2 o'clock, P. M. The condition of the wound remains unchanged. The cough has not been so frequent or persistent, but the sputa still remain purulent. Nourishment and stimulants have been given in increased quantities without discomfort. Altogether, his general condition cannot be said to be improved.

TO LOWELL, Minister, London:—

There has been no very marked change in the President's condition, but it is not at this hour (10.30 P. M.) reassuring. The different symptoms are almost all slightly aggravated. The temperature and the pulse have fluctuated more than usual, and the respiration is rather more frequent, while the character of the discharges continue to be unsatisfactory. There is, therefore, a sensible increase of anxiety.

MACVEAGH.

LONG BRANCH, N. J., September 17, 1881, 9 A. M.

At the morning examination and dressing of the President the temperature was 99.8°, pulse 108, and respiration 21. The fluctuations of the pulse during the night varied from 116 to 130. The temperature during this time not deviating much from normal. He slept quite well, taking nourishment at proper intervals. His cough was not troublesome, and the expectoration moderate. The discharge from the wound is more healthy, and the color of the granulations slightly improved.

At the examination of the President at 12 M., to-day, the temperature was 102°, pulse 120, respiration 24. At 11.30 A. M. he had a severe chill, lasting half an hour, followed by perspiration.

6 P. M. Since the noon examination there has been a gradual fall of temperature, with diminished frequency of pulse and respiration, so that, at the evening examination, the temperature was 98°, pulse 102, respiration 18. He has slept most of the time during the afternoon, and has taken his nourishment at proper intervals. The cough has been less frequent than usual.

TO LOWELL, London:—

The President had a severe chill this forenoon, lasting for half an hour, and followed by considerable fever and perspiration. Since then there has been a gradual decrease in pulse, temperature, and respiration, and he has slept most of the time. There has been no gain in strength nor any evidence of repair, and the situation is now, probably, more grave and critical than at any time heretofore.

MACVEAGH.

TO LOWELL, London:—

The President passed a comparatively quiet and comfortable day, but this evening he had another chill, of less duration than that of yesterday, but sufficient to increase the very great anxiety already existing. He has also been slowly growing weaker, and his present condition excites the gravest apprehensions.

MACVEAGH.

LONG BRANCH, N. J., September 18, 1881, 9.30 A. M.

At the examination of the President at 8.30 A. M., the temperature was 98°, pulse 102, respiration 18. There was no perceptible febrile rise during the night, the pulse ranging from 102 to 112. The cough was less troublesome than on previous nights, and the expectoration unchanged. He is able to take nourishment and stimulants required, without gastric disturbance, nor has there been evidence of mental aberration during the night.

6 P. M. The President, though quite weak, has passed a very quiet day. There has been no recurrence of chill nor mental

disturbance. At 9 A. M. a slight febrile rise took place and began to subside at 11 o'clock, at which time the temperature was 100°, pulse 116, respiration 20. There has been no increase of cough or change in the character of the expectoration. At the evening examination, 5.30 P. M., the temperature was 98.4°, pulse 102, respiration 20.

LONG BRANCH, N. J., September 19, 1881, 9 A. M.

The condition of the President this morning continues unfavorable. Shortly after the issue of the evening bulletin he had a chill lasting fifteen minutes. The febrile rise to lowing continued until 12 midnight, during which time the pulse ranged from 112 to 130. The sweating that followed was quite profuse. The cough, which was troublesome during the chill, gave him but little annoyance the remainder of the night. This morning at 8 A. M. the temperature was 98.8°, pulse 106 and feeble, respiration 22. At 8.30 another chill came on, on account of which the dressing was temporarily postponed. A bulletin will be issued at 12.30 P. M.

12.30 P. M. The chill from which the President was suffering at the time the morning bulletin was issued lasted about fifteen minutes, and was followed by a febrile rise of temperature and sweating. He has slept much of the time, but his general condition has not materially changed since. Temperature 98.2°, pulse 104, respiration 20.

6 P. M. Though the gravity of the President's condition continues, there has been no aggravation of symptoms since the noon bulletin was issued. He has slept most of the time, coughing but little and with ease. The sputa remains unchanged. A sufficient amount of nourishment has been taken and retained. Temperature 98.4°, pulse 102, respiration 18.

TO LOWELL, Minister, London:—

The President had another chill of considerable severity this morning, which, following so soon after the chill of last evening, left him very weak indeed. His pulse became more frequent and feeble than at any time since he recovered from the immediate shock of the wound, and his general condition was more alarming during the day. His system has reacted to some extent, and he passed the afternoon and evening comfortably. At this hour he is resting quietly, and no disturbance is expected during the night. There has been, however, no gain whatever in strength, and there is, therefore, no decrease of anxiety.

MACVEAGH.

ELBERON, N. J., September 19, 1881, 11.30 P. M.

The President died at 10.35 P. M. After the bulletin was issued at 5.30 this evening the President continued in much the same condition as during the afternoon, the pulse varying from 102 to 106, with rather increased force and volume. After taking nourishment he fell into a quiet sleep about 35 minutes before his death, and while asleep his pulse rose to 120, and was somewhat more feeble. At 10 minutes after 10 o'clock he awoke complaining of severe pain over the region of the heart, and almost immediately became unconscious and ceased to breathe at 10.35.

D. W. BLISS,

FRANK H. HAMILTON,

D. HAYES AGNEW.

LONG BRANCH, N. J., September 20, 11 P. M.

By previous arrangement a post-mortem examination of the body of President Garfield was made this afternoon in the presence and with the assistance of Drs. Hamilton, Agnew, Bliss, Barnes, Woodward, Reyburn, Andrew H. Smith, of Elberon, and Acting-Assistant Surgeon D. S. Lamb, of the army medical museum, Washington. The operation was performed by Dr. Lamb. It was found that the ball, after fracturing the right eleventh rib, had passed through the spinal column, in front of the spinal canal, fracturing the body of the first lumbar vertebra, driving a number of small fragments of bone into the adjacent soft parts, and lodging just below the pancreas about two inches and a half to the left of the spine, and behind the peritoneum, where it had become completely encysted. The immediate cause of death was secondary hemorrhage from one of the mesenteric arteries adjoining the track of the ball, the blood rupturing the peritoneum, and nearly a pint escaping into the abdominal cavity. The hemorrhage is believed to have been the cause of the severe pain in the lower part of the chest complained of just before death. An abscess cavity, six inches by four in dimensions, was found in the vicinity of the gall bladder, between the liver and the transverse colon, which was strongly inter-adherent. It did not involve the substance of the liver, and no communication was found between it and the wound. A long suppurating channel extended from the external wound between the loin muscles and the right kidney, almost to the right groin. This channel, now known to be due to the burrowing of pus from the wound, was supposed during life to have been the track of

* Removed to Long Branch.

the ball. On an examination of the organs of the chest evidences of severe bronchitis were found on both sides, with broncho-pneumonia of the lower portions of the right lung, and, though to a much less extent, of the left. The lungs contained no abscesses and the heart no clots. The liver was enlarged and fatty, but free from abscesses; nor were any found in any other organ except the left kidney, which contained, near its surface, a small abscess about one third of an inch in diameter. In reviewing the history of the case in connection with the autopsy, it is quite evident that the different suppurating surfaces, and especially the fractured spongy tissue of the vertebrae, furnish a sufficient explanation of the septic condition which existed.

Recent Literature.

Atlas of Skin Diseases. By LOUIS A. DUHRING, M. D., etc. Part IX. Philadelphia: J. B. Lippincott & Co. 1881.

The ninth part of Professor Duhring's *Atlas of Skin Diseases* has appeared. It consists of four admirably-executed plates: two of eczema rubrum, one of pemphigus, and one of ecthyma. Eight times already have we expressed our ever-increasing admiration of this remarkable series of representations of cutaneous affections, nothing even approaching which has ever yet been offered to the world, if we, perhaps, except the works of F. Hebra and H. C. Hebra in the *Vienna Atlas*. We need not labor to what we have previously written in the *Journal* upon this subject, but we can reassert and confirm it, and the fact that the present number completes the series leads us to take this final opportunity to once more recommend the work.

To briefly summarize, then: it is, as stated, the best atlas of the kind. It is good consistently, from the first to the final plate, not, as is usually the case, steadily degenerating after the first number issued to draw subscriptions. It portrays the cases which it is the lot of the physician to encounter, not the wonderment-provoking monstrosities of the specialty. The accompanying text is, of course, excellent, as might be expected, coming from the author of *Diseases of the Skin*, the best book ever published upon this subject for English-speaking physicians.

This concluding number contains a complete list of contents, and Dr. Duhring's classification of diseases of the skin is also appended. The work is *par excellence* the atlas to study and to purchase. E. W.

The Care of Infants. By JOHN A. KEATING, M. D., Lecturer on Diseases of Children at the University of Pennsylvania, etc. Philadelphia: Henry C. Lea's Son & Co. 1881.

This little "guide" has been written by the author at the request of "some young mothers who have placed themselves and their children under his guidance," and who have urged him "to give them a little book."

To such we have no doubt it will prove a great help and comfort, and will supply a want which all young mothers must at times experience, namely, for concise and practical directions in black and white, so to speak, upon questions liable to arise daily, and a knowledge of which, the author rightly says, only lengthy visits of the physician would enable him to impart. To these the instructions will come with an authority which only the family physician possesses in virtue of the confidence and trust placed in him. This little book, however, possesses many merits entitling it to a wider circle of readers, which we have no hesitation of predicting for it.

Medical and Surgical Journal.

THURSDAY, OCTOBER 6, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.

HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

A REORGANIZATION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

WE are glad to note the attempt to infuse new life into the dormant sections of the Suffolk District Medical Society. This Society, being the representative of the Massachusetts Medical Society in Boston, should represent it worthily; to this end it should be the exponent of the best medical work and thought in the district. Being free from the reproach of exclusiveness, its field of usefulness should be more extended than that of other medical societies, and its meetings should furnish evidence of a high standard of professional attainments, and afford a field of impartial and trenchant criticism, so essential to the preservation of such a standard. In this way only can the Society become an educator and fulfill the acknowledged end of its existence — medical improvement. In the present multiplicity of subjects the general transactions of a society naturally fail to represent fully the separate special interests of the individual members, and experience elsewhere has proved the sectional plan of work to be the one best adapted to secure such interest and participation.

Some years ago the Suffolk District Society was divided into eight sections, in the hopes that the individual interest in the Society might be increased. Hitherto this has not been the case, the other medical societies having assumed, perhaps naturally, from their restricted membership, a more important position in the minds of many. Another cause of failure was the too extreme subdivision of the sections, the body of the profession not being large enough to justify this. Some months since the sections of surgery and clinical medicine and pathology each held an experimental meeting. The unanimous opinion of those present was in favor of continuing these meetings during the coming winter. The committee of supervision of the general Society, believing the time ripe for another attempt to awaken the interest of the members, recommended to the Society that the number of general meetings be reduced to four annually, in order that a better opportunity might be given for sectional work. The report of the committee was adopted. During the coming Society year the two sections previously mentioned, and that of obstetrics and gynecology, will meet at such intervals as the members may determine. Membership may be acquired by simply notifying the secretary of the general Society of the section or sections which one wishes to join.

We heartily sympathize with this movement, and

wish it entire success. There is a strong feeling among the younger portion of the profession that the need for the existence of so many medical societies has passed away, and that the Suffolk should become the most important and representative, if not the only one. There is a certain amount of justice in the charge that hitherto the other societies have monopolized the best material, and closed their doors against some of those who should benefit by it. It is no justification to plead that the transactions are published; *virtu voce* is as needful for the busy practitioner as for the student. One with large opportunities for observation owes a duty to his less favored brother practitioner as well as to the student, a duty not always recognized as fully as it might be.

That worthless material and perhaps unpleasant criticism can only be excluded by a restricted membership is an argument, which has all the defects of its merits; a medical society may more profitably and successfully crush out the bad by the preponderance of good, and honest criticism, however aggressive, is less dangerous than its repression.

The success of this movement in the Suffolk District Society depends on the amount of legitimate interest aroused and work done in these several sections. There is the best opportunity there for free discussion and criticism. A common interest should stimulate these, but the impulse must be general, and those who wish the Suffolk District Medical Society to advance must put their own shoulders to the wheel, and not content themselves with approving the efforts of their neighbors. There must be a consensus of hearts and hands based upon a persistent rather than a spasmodic determination to accomplish the desired result.

THE ISLE OF WIGHT.

THE sanitary condition of the Isle of Wight has been for some time viewed with suspicion by those knowing something about it. Both the water supply and the drainage of various parts of the island to which invalids — and among these many Americans — are accustomed to resort, have been regarded as defective. Dr. Ballard, the well-known English health officer, has recently reported the results of an investigation undertaken at the request of the Local Government Board, results confirmatory of the most unfavorable suspicions entertained. It is well that our countrymen seeking for health or pleasure should be on their guard in visiting this favorite resort until the evils complained of shall have been corrected. It is not worth while to go so far to get typhoid fever, a disease which can be indulged in at many spots, otherwise not unattractive, much nearer home.

From a late number of the *London Practitioner* we select some remarks upon the condition of the island, and Dr. Ballard's report:—

"To the tourist and health-seeker alike the Isle of Wight — the so-called Garden of England — is, perhaps, the most fascinating resort in Great Britain. Whatever would tend to derogate from this view of the island should be regarded as much as a general as

a local calamity. Yet, strange to say, so heedless are the inhabitants and their representatives of this matter that they would appear to have entered into an unavowed but not less real conspiracy to damage the reputation of the island both as a pleasure and a health resort in the opinion of outsiders.

"The Local Government Board, having resolved to subject the sanitary administration of the island to investigation, delegated the task of inquiry to Dr. Ballard. This gentleman's report on the subject has now been made public, and it is of a nature which will cause all thoughtful persons to reflect before they enter upon the perilous course (for such it would appear to be) of visiting this island either for pleasure or for health. The island, it would appear, for sanitary purposes, is placed under the supervision of nine several sanitary authorities, each separate from, and acting independently of, the others, recognizing no common interest, and possessing no means of coördination. The result of such an organization (if the term organization may be applied to what on the face is an obvious disorganization) is that the sanitary affairs of the island are in the utmost state of confusion, and that the authorities, who should be responsible for keeping the island free from those accidental sources of impurity which necessarily accompany houses and communities, have done nothing of the sort, or done so only in the incompletest fashion, and that the island has become defaced by conditions detrimental in the highest degree to its own inhabitants, and peculiarly detrimental to the health and well-being of visitors. There would seem to have happened in the Isle of Wight that which has happened too often in health resorts elsewhere, that the inhabitants, satisfied with the advantages they derive from their topographical position, advantages here apparently sealed by the approval of royalty, have held themselves absolved from careful attention to those subsidiary conditions of wholesomeness which attach to the regulations of buildings and the provisions for the ordinary conditions of domestic life. Let us endeavor to illustrate these points from Dr. Ballard's description of the state of the several sanitary districts into which the island is divided.

"Enteric fever claims attention equally in the rural districts of the island as in other districts, and Dr. Ballard's report shows that there is no part of the island to which the visitor can go without exposing himself to peril in consequence of the shortcomings of its sanitary authority. In fact, it would almost appear as if the sanitary authorities of this beautiful spot had determined (however unintentionally) that from being known as the Garden of England, the Isle of Wight should become known as the Midden-land of Southern England."

CONTRIBUTION TO MALARIA IN NEW ENGLAND.

WE learn that eight or ten cases of intermittent fever of unquestionable local origin have been observed in Millbury, in this State. Millbury, as our

readers know, is a pleasant manufacturing town of about 5000 inhabitants, situated on the Blackstone River, not far from Worcester.

COMPULSORY RETURNS OF TYPHOID FEVER.

THE Boston Board of Health have notified the physicians of the city that hereafter typhoid fever, in addition to small-pox, scarlet fever, typhus fever, and diphtheria, will be regarded as falling within the meaning of Chapter 26 of the General Statutes. The return of all cases of typhoid to the Board is therefore compulsory under penalty of the usual fine.

This step has doubtless been hastened by the rather unusual frequency of typhoid in this city and elsewhere this summer. In itself it should cause no alarm to householders. It is so proper that typhoid fever should be classed with the other diseases whose return is compulsory that it is only surprising this was not done before. There is no disease whose spread may be more easily controlled by suitable precautions and supervision, at the same time that there is no disease more constantly and regularly amongst us.

MEDICAL NOTES.

—The seventh annual meeting of the Tri-State Medical Society will be held in St. Louis, October 25, 26, 27, 1881. The headquarters of the association will be at the Lindell Hotel, and the sessions will be held in the ladies' ordinary of the hotel. Three sessions will be held each day. Each session will be called promptly. The rule limiting papers to twenty-five minutes will be strictly enforced. Time for discussion will be given after each paper, or series of papers. A social entertainment will be given if there is time, — not otherwise.

PHILADELPHIA.

—The various medical and dental schools in this city began their preliminary lectures September 5th; the regular winter session will open October 3d. During the summer extensive alterations have been going on at Jefferson; the classical front with its Corinthian pillars is a thing of the past. The college now comes out with a new face of ornamented brick, to match the adjoining laboratory building erected some years ago. It is said that the additional room gained by the change in the front will increase the seating capacity of each of the two large lecture halls by about one hundred. An additional dissecting room has also been obtained by building another story on the back of the college. Opportunity has been taken to improve the ventilation, which was greatly needed. All of the schools in Philadelphia anticipate larger classes this winter than last one, and a goodly number of students are already in the city.

—The Board of Health (so called) of this city have earned the reputation of devoting the greater part of their intellectual energy and valuable time to

the discussion of questions of mainly personal interest (the medical members being in the minority). The contractors for street-cleaning having for a long time notoriously slighted or neglected the duties for which they were paid, the Board of Health has made some spasmodic efforts to have the work done, but apparently without much effect. The streets are so dirty in many places as to directly invite disease, and it would defy Hercules to restore them to a condition creditable to Philadelphia. In the mean time zymotic disease is ever with us. Small-pox is again on the increase; after existing here for nearly two years it still claims its weekly quota of deaths, no efficient steps having been taken towards stopping its course. It seems to be the prevailing belief among our city fathers that all that is needed to check an epidemic of small-pox is free vaccination. This is encouraging to the friends of vaccination, but it is hardly the whole duty of a sanitary board in the premises. It is really not surprising that the epidemic continues, since there is no satisfactory and systematic plan in use for the disinfection of clothing and bedding or the destruction of fomites; there is no isolation and quarantining of the sick; there is no house-to-house visitation, and no penalty for communicating the disease. To make matters worse, the appropriation for public vaccination for the year is about exhausted, and unless some special appropriation can be obtained vaccination will have to be stopped just at the beginning of winter. On account of this recent increase of the number of cases of small-pox, a committee of the County Medical Society, at its meeting, September 14th, was appointed to confer with the Board of Health, in order to offer and to devise some plan for restricting the further progress of the disease.

— The Philadelphia County Medical Society is in a very flourishing condition. It has about three hundred members. A new standing committee on Clinical Pathology has just been appointed which proposes to hold monthly meetings. At the first meeting, held September 21st, the following papers were read and discussed: Dr. Lewis on the Treatment of Varicocele by Excision of Redundant Scrotum, the operation being illustrated by patients; Dr. Eskridge presented a specimen of Cancer of the Esophagus and Mediastinum involving Heart and Great Vessels; Dr. Mills exhibited patients with Neuritis; Dr. Breen reported a Case of Abscess of the Liver, with a specimen; Dr. Leffmann showed a new mode of Detecting Albumen (by using powdered glacial phosphoric acid); and Dr. Roberts initiated a very interesting discussion on Gonorrhoea. At the first meeting of the whole Society this fall Dr. C. Seiler read a paper on the Use of the Galvano-Cautery, and exhibited his own battery and the ingenious method of using it.

— Registration of practitioners is going on still; about 1075 have thus far recorded their names and shown their authority to practice. The health office gives the number of persons practicing midwifery as about 1300; it is estimated that there are altogether about 1700 doctors in this city. We are anxious to see if any one has the courage to prosecute a physician,

illegally practicing, in order to determine the constitutionality of the law itself, of which there are some doubts.

— A large general hospital is to be built in the southern part of the city under the auspices of the Roman Catholic Church; it will be called the St. Agnes Hospital, and will prove a welcome addition to our list of hospitals, as their capacity has been severely tested this fall.

— Our errant colleagues, delegates to the International, have all returned, and appear to have greatly enjoyed their reception in London.

CHICAGO.

— This city is having an experience with typhoid fever such as it has not had before for many years. The last half of 1880 witnessed a large increase in cases of this disease over former years, but this year has been very much worse than last. Cook County Hospital, with three hundred and fifty beds, which usually at this season has not more than half a dozen contains now between seventy and eighty cases. At the same time last year the number in the wards was not more than fifteen or twenty.

— The readers of the *JOURNAL* are aware from the public prints and from accurate reports in your own columns of the continuance of small-pox among us. It seems next to impossible to eradicate it. Most faithful and persistent have been the efforts of the Health Department in following up the cases, as fast as they are discovered, by systematic vaccinations of all the people in the neighborhood. But many cases have been secreted till they have spread the contagion to large numbers of people; in several instances they have only been discovered by a physician being applied to for a death certificate. A few years ago the city council passed an ordinance requiring the Health Department, in every instance of this disease, to remove the patient to the Small-Pox Hospital. This season it has become impossible to carry out this law, and so it is to a large degree a dead letter. Many patients are treated at their homes.

Miscellany.

THE AMERICAN EDITION OF HOLMES' SURGERY.

SOME remarks on the prospective American edition of Holmes' Surgery contained in a London letter which appeared in the *JOURNAL* of September 8th, page 237, as we are informed by the publishers, does them much injustice, which, had it been brought to his notice, the lamented writer of the letter, we are sure, would have been anxious to correct. It seems that the English publishers of Holmes' System of Surgery (Messrs. Longman & Co.) are likewise its owners, that they were informed of the intention of Messrs. Henry C. Lea's Son & Co. to publish an American edition of the work, and that an offer was made for the purchase of the woodcuts, and a further sum was tendered in consideration of the republication. Messrs. Henry C. Lea's Son & Co. are advocates of an international copyright.

Deaths reported 2928 (no report from New Orleans); 1440 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1061, diarrhoeal diseases 531, consumption 335, diphtheria and croup 185, lung diseases 150, typhoid fever 102, small-pox 67, malarial fevers 60, scarlet fever 39, whooping-cough 30, cerebro-spinal meningitis 18, puerperal fever 15, measles eight, erysipelas five, typhus fever one. From *small-pox*, Chicago 35, Pittsburgh 19, Philadelphia 10, New York two, St. Louis one. From *malarial fevers*, New York 17, Brooklyn and St. Louis 10, Chicago and District of Columbia five, Baltimore and Buffalo four, Philadelphia and Cincinnati two, New Haven one. From *scarlet fever*, New York 13, Brooklyn and Pittsburgh six, St. Louis four, Philadelphia three, Baltimore two, Chicago, Cincinnati, Buffalo, Milwaukee, and New Bedford one. From *whooping-cough*, New York seven, Chicago six, Baltimore five, Brooklyn, Boston, and Newton two, Philadelphia, St. Louis, Pittsburgh, Providence, Cambridge, and Fall River one. From *cerebro-spinal meningitis*, New York five, Worcester three, Chicago and Lynn two, Philadelphia, St. Louis, Pittsburgh, Buffalo, Fall River, and Chelsea one. From *puerperal fever*, St. Louis three, Chicago, Boston, and Buffalo two, Philadelphia, Cincinnati, District of Columbia, Lynn, Pittsfield, and Plymouth one. From *measles*, Chicago two, New York, Boston, Cincinnati, District of Columbia, Pittsburgh, and Buffalo one. From *erysipelas*, Chicago, Baltimore, Pittsburgh, Buffalo, and Pittsfield one. From *typhus fever*, Gloucester one. Few deaths occurred in New York and two in Buffalo from direct effects of cold heat.

One case of small-pox was reported in Brooklyn, 45 in Pittsburgh, deaths 142 in Boston; scarlet fever eight, diphtheria 10, in Milwaukee. Diphtheria is still endemic in Buffalo.

In French's latest census of Massachusetts, with a population of

1,021,061 (population of the State 1,783,086), the total death-rate for the week was 21.03 against 24.81 and 26.74 for the previous two weeks.

For the week ending August 27th in 149 German cities and towns, with estimated populations of 7,840,235, the death-rate was 26.8. Deaths reported 4037; under five 2283; pulmonary consumption 478, diarrhoeal diseases 377, acute diseases of the respiratory organs 203, diphtheria and croup 128, scarlet fever 102, whooping-cough 66, typhoid fever 55, puerperal fever 18, measles and *roteln* 17, small-pox (Dresden) one. The death-rates ranged from 13.6 in Mannheim to 45.1 in Posen; Königsberg 29.9; Breslau 43; Munich 38; Dresden 26.4; Berlin 27.8; Leipzig 24; Hamburg 22.6; Hanover 24.6; Bremen 14.6; Cologne 30.9; Frankfurt 16.4; Strassburg 27.9.

The English returns for the week ending August 27th have not been received.

For the week ending September 3d in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 17.4. Deaths reported 2542; diarrhoea 185, scarlet fever 113, whooping-cough 62, measles 51, fever 36, small-pox (London) 22, diphtheria 19. The death-rates ranged from 13 in Brighton to 25.4 in Leicester; Birmingham 14.3; London 16.2; Leeds 17.8; Bristol 18.4; Manchester 19.4; Sheffield 20.3; Liverpool 22.7. In Edinburgh 18.2; Glasgow 21.2; Dublin 16.6.

For the week ending September 3d in the 21 chief towns of Switzerland, population 479,934, there were 52 deaths from diarrhoeal diseases; acute diseases of the respiratory organs 15, typhoid fever eight, whooping-cough seven, diphtheria and croup two, measles one, small-pox one. The death-rates were Geneva 25; Zurich 16.2; Basle 18.1; Bern 30.4.

The meteorological record for the week in Boston was as follows:—

Deaths reported 2961 (no report from New Orleans): 1390 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1005, diarrhoeal diseases 424, consumption 390, diphtheria and croup 207, lung diseases 166, typhoid fever 128, malarial fevers 62, small-pox 55, scarlet fever 42, whooping-cough 34, cerebro-spinal meningitis 23, puerperal fever 14, erysipelas nine, typhus fever five, measles two. From malarial fevers, St. Louis 24, Brooklyn 10, District of Columbia eight, Baltimore six, Chicago four, Philadelphia three, Buffalo, New Haven, and Newburyport two, Nashville one. From small-

pox, Chicago 26, Pittsburgh 16, Philadelphia 12, New York one. From scarlet fever, New York 23, Brooklyn six, Philadelphia five, Pittsburgh three, Chicago, St. Louis, Cincinnati, District of Columbia, and Worcester one. From whooping-cough, Chicago, Boston, and Baltimore six, New York and Philadelphia three, Brooklyn, St. Louis, Buffalo, and Providence two, Nash- and Salem one. From cerebro-spinal meningitis, New York five, Lynn three, Philadelphia and Chicago two, St. Louis, Baltimore, Cincinnati, Pittsburgh, Buffalo, Milwaukee, Lowell, Cambridge, Newton, Bridgewater, and Holliston one. From puerperal fever, Boston and Lowell two, New York, Brooklyn.

Chicago, St. Louis, Cincinnati, District of Columbia, Pittsburgh, Cambridge, Fall River, and Lynn one. From *erysipelas*, New York four, Philadelphia, Brooklyn, Chicago, Boston, and Baltimore one. From *typhus fever*, Chicago three, New York two. From *measles*, New York, and Buffalo one.

Thirteen cases of small-pox were reported in New York, two in Brooklyn, two in St. Louis, two in Cincinnati, 17 in Pittsburgh, and two in Milwaukee; diphtheria 30, scarlet fever seven in Boston; diphtheria 11, scarlet fever five, in Milwaukee. Dy-entery still epidemic in Buffalo.

In 38 cities and towns of Massachusetts, with a population of 977,645 (population of the State 1,783,086), the total death-rate for the week was 22.99 against 21.03 and 24.81 for the previous two weeks.

For the week ending September 3d in 149 German cities and towns, with estimated populations of 7,936,736, the death-rate was 24.4. Deaths reported 3720; under five 2021; pulmonary consumption 433, diarrhoeal diseases 322, acute diseases of the respiratory organs 487, scarlet fever 118, diphtheria and croup 100, typhoid fever 93, whooping cough 67, puerperal fever 19, measles and *rotheln* 16, small-pox (Königsberg, Aachen) two,

typhus fever (Königsberg) two. The death-rates ranged from 10.4 in Weisbaden to 46.7 in Posen; Königsberg 24.4; Breslau 32.6; Munich 30.1; Dresden 25.3; Berlin 26; Leipzig 20.9; Hamburg 22.2; Hanover 19; Bremen 22.8; Cologne 25.1; Frankfurt 14.9; Strassburg 21.7.

For the week ending September 10th in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 18.1. Deaths reported 2636; diarrhoea 140, scarlet fever 115, whooping-cough 67, measles 51, fever 43, small-pox (London) 27, diphtheria 16. The death-rates ranged from 12.6 in Brighton to 26.9 in Hull; Birmingham 14.5; Bristol 16.1; Leeds 16.3; London 16.7; Sheffield 17.5; Manchester 23.4; Liverpool 24.2; Edinburgh 18.0; Glasgow 28.0; Dublin 19.3.

For the week ending September 10th in the 21 chief towns of Switzerland, population 479,934, there were 42 deaths from diarrhoeal diseases; acute diseases of the respiratory organs eight, diphtheria and croup seven, typhoid fever five, whooping-cough four, small-pox none, measles none, scarlet fever none. The death-rates were Geneva 13.5; Zurich 17.6; Basle 17.6; Berne 24.6.

The meteorological record for the week in Boston was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM SEPTEMBER 24, 1881, TO SEPTEMBER 30, 1881.

ALEXANDER, R. H., major and surgeon. Relieved from duty in Department of the East to take effect October 1, 1881, and granted leave of absence for three months, with permission to apply for one month's extension; at expiration thereof to report by letter to the Surgeon-General. S. O. 215, A. G. O., September 19, 1881.

HENSTINGTON, D. L., major and surgeon. Relieved from duty as attending surgeon at the Soldiers' Home, D. C., and to report in person to the Surgeon-General for duty as curator of the Army Medical Museum, and to take charge of the division of surgical records of the Surgeon-General's Office. S. O. 217, A. G. O., September 24, 1881.

KING, WILLIAM H., captain and assistant surgeon. When relieved by Assistant Surgeon Turrill to proceed to Governor's Island, New York Harbor, and report in person at those headquarters. S. O. 170, Department of the East, September 24, 1881.

DEWITT, C., captain and assistant surgeon. Now on leave of absence, to report in person to the Governor of the Soldiers' Home, D. C., for duty as attending surgeon at the Home. S. O. 217, C. S., A. G. O.

HELMANN, CHARLES, captain and assistant surgeon. Re-

lieved from duty at Fort Townsend, W. T., and assigned to duty at Vancouver Barracks, W. T., as post medical officer, relieving Assistant Surgeon Dickson. S. O. 135, Department of the Columbia, September 9, 1881.

SKINNER, J. O., captain and assistant surgeon. Relieved from duty at Fort Verde, A. T., and to proceed to Wilcox, A. T., for duty as acting medical purveyor in the field. S. O. 107, Department of Arizona, September 17, 1881.

GRAY, WILLIAM W., first lieutenant and assistant surgeon. Relieved from duty at Fort Canby, W. T., and assigned to duty at Fort Townsend, W. T. S. O. 135, C. S., Department of the Columbia.

BOOKS AND PAMPHLETS RECEIVED.—A Hand-Book of Vertebrate Dissection. By H. Newell Martin, D. Sc., and William H. Moale, M. D. Part I. How to Dissect a Chelonian. New York: Macmillan & Co. 1881.

Nature Series. Fashion in Deformity, as illustrated in the Customs of Barbarous and Civilized Races. By William Henry Flower, Hunterian Professor of Comparative Anatomy and Conservator of the Museum of the Royal College of Surgeons of England. With Illustrations. London: Macmillan & Co. 1881.

Refraction of the Eye. Its Diagnosis and the Correction of its Errors, with Chapters on Keratotomy. By A. Stanford Morton, F. R. C. S., Ed. Philadelphia: Presley Blakiston. 1881.

Legislation.

REGULATION OF THE PRACTICE OF MEDICINE IN THE UNITED STATES.¹

LITTLE has been done in this country until within a few years to exercise any control over the practice of medicine. Absolute freedom has been allowed every one who desired to take the responsibility of treating disease, even if he possessed no knowledge whatever. Indeed, it is a matter of record that the law has actually protected an individual from the results of his work on the plea of ignorance, thus showing an absence of evil intent. We give the more prominent of the laws which have been passed in different States. The California law resembles closely that of Illinois, a Board of Examiners being substituted for the Board of Health. The Vermont law resembles that of New Hampshire. Laws exist also in Alabama and Texas. A Medical Registry Law has lately been passed in Pennsylvania. Rather more active efforts are being made to enforce the New York Registry Law, but without results to record.

NEW YORK.

Chapter 513. An act entitled An Act to regulate the Licensing of Physicians and Surgeons. Passed May 29, 1880, three fifths being present.

The people of the State of New York, represented in Senate and Assembly, do enact as follows:—

Section I. A person shall not practice physic or surgery within the State unless he is twenty-one years of age, and either has been heretofore authorized so to do, pursuant to the laws in force at the time of his authorization, or is hereafter authorized so to do as prescribed by chapter seven hundred and forty-six of the laws of eighteen hundred and seventy-two,² or by subsequent sections of this act.

Section II. Every person now lawfully engaged in the practice of physic and surgery within the State shall, on or before the first day of October, eighteen hundred and eighty, and every person hereafter duly authorized to practice physic and surgery, shall, before commencing to practice, register in the clerk's office of the county where he is practicing, or intends to commence the practice of, physic and surgery, in a book to be kept by said clerk, his name, residence, and place of birth, together with his authority for so practicing physic and surgery as prescribed in this act. The person so registering shall subscribe and verify by oath or affirmation, before a person duly qualified to administer oaths under the laws of the State, an affidavit containing such facts, and whether such authority is by diploma or license, and the date of the same, and by whom granted, which, if willfully false, shall subject the affiant to conviction and punishment for perjury. The county clerk to receive a fee of twenty-five cents for such registration, to be paid by the person so registering.

Section III. A person who violates either of the two preceding sections of this act, or who shall practice physic or surgery under cover of a diploma illegally obtained, shall be deemed to be guilty of a misdemeanor, and on conviction shall be punished by a fine of not less than fifty dollars nor more than two hundred dollars for the first offense, and for each subsequent offense by a fine of not less than one hundred dollars nor more than five hundred dollars, or by imprisonment for not less than thirty days nor more than ninety days, or both. The fine when collected shall be paid, the one half to the person or corporation making the complaint, the other half into the county treasury.

Section IV. A person coming to the State from without the State may be licensed to practice physic and surgery, or either, within the State, in the following manner: If he has a diploma conferring upon him the degree of doctor of medicine, issued by an incorporated university, medical college, or medical school without the State, he shall exhibit the same to the faculty of some incorporated medical college or medical school of this State, with satisfactory evidence of his good moral character, and such other evidence, if any, of his qualifications as a physician or surgeon as said faculty may require. If his diploma and qualifications are approved by them, then they shall

indorse said diploma, which shall make it for the purpose of his license to practice medicine and surgery within this State the same as if issued by them. The applicant shall pay to the dean of said faculty the sum of twenty dollars for such examination and indorsement. This indorsed diploma shall authorize him to practice physic and surgery within the State upon his complying with the provisions of Section II. of this act.

Section V. The degree of doctor of medicine lawfully conferred by any incorporated medical college or university in this State shall be a license to practice physic and surgery within the State after the person to whom it is granted shall have complied with Section II. of this act.

Section VI. Nothing in this act shall apply to commissioned medical officers of the United States army or navy, or of the United States marine hospital service. Nor shall it apply to any person who has practiced medicine and surgery for ten years last past, and who is now pursuing the study of medicine and surgery in any legally incorporated medical college within this State, and who shall graduate from and receive a diploma within two years from the passage of this act.

Section VII. All acts or parts of acts inconsistent with the provisions of this act are hereby repealed.

STATE OF NEW YORK,
Office of the Secretary of State. } ss.:

I have compared the preceding with the original law on file in this office, and do hereby certify that the same is a correct transcript therefrom and of the whole of said original law.

JOSEPH B. CAIR,
Secretary of State.

Chapter 746. An act relating to the examination of candidates for the degree of doctor of medicine. Passed May 16, 1872.

The people of the State of New York, represented in Senate and Assembly, do enact as follows:—

Section I. The regents of the University of the State of New York shall appoint one or more Boards of Examiners in medicine, each board to consist of not less than seven members, who shall have been licensed to practice physic and surgery in this State.

Section II. Such examiners shall faithfully examine all candidates referred to them for that purpose by the chancellor of said university, and furnish him a detailed report in writing of all the questions and answers of each examination, together with a separate written opinion of each examiner as to the acquirements and merits of the candidates in each case.

Section III. Such examinations shall be in anatomy, physiology, materia medica, pathology, histology, clinical medicine, chemistry, surgery, midwifery, and in therapeutics, according to each of the systems of practice represented by the several medical societies of the State.

Section IV. The said reports of examinations and the annexed opinions of the examiners shall forever be a part of the public records of the said university, and the orders of the chancellor addressed to the examiners, together with the action of the regents, in each case, shall accompany the same.

Section V. Any person over twenty-one years of age, of good moral character, and paying not less than thirty-five dollars into the treasury of the university, and on applying to the chancellor for the aforesaid examination, shall receive an order to that effect, addressed to one of the Boards of Examiners, provided he shall adduce proofs satisfactory to the chancellor that he or she has a competent knowledge of all the branches of learning taught in the common schools of this State, and of the Latin language, and that he has diligently studied medicine not less than three years, under the direction of one or more physicians duly qualified to practice medicine, or has himself been licensed, on examination, by some medical society or college legally empowered to issue licenses or degrees in medicine.

Section VI. The regents of the university, on receiving the aforesaid reports of the examiners, and on finding that not less than five members of a board have voted in favor of a candidate, shall issue to him or her a diploma conferring the degree of doctor of medicine of the University of the State of New York, which degree shall be a license to practice physic and surgery.

Section VII. The candidate, on receiving said diploma, shall pay to the university the further sum of not less than ten dollars.

Section VIII. The moneys paid to the university, as aforesaid, shall be appropriated by the regents for the expenses of executing the provisions of this act.

Section IX. The regents may establish such rules and regulations, from time to time, as they may deem necessary to insure the faithful execution of the provisions of this act.

Section X. This act shall take effect immediately.

² This chapter follows the act.

ILLINOIS.

The following is a full copy of An Act to regulate the Practice of Medicine in the State of Illinois. Approved May 29, 1877. In force July 1, 1877:—

Be it enacted by the people of the State of Illinois, represented in the General Assembly: Section I. That every person practicing medicine, in any of its departments, shall possess the qualifications required by this act. If a graduate in medicine, he shall present his diploma to the State Board of Health, if such Board of Health shall be established by law, or Board of Examiners herein named, for verification as to its genuineness. If the diploma is found genuine, and if the person named therein be the person claiming and presenting the same, the State Board of Health, if such Board of Health shall be established by law, or the Board of Examiners, shall issue its certificate to that effect, signed by all of the members thereof, and such diploma and certificate shall be conclusive as to the right of the lawful holder of the same to practice medicine in this State. If not a graduate, the person practicing medicine in this State shall present himself before said board, and submit himself to such examinations as the said board shall require; and if the examination be satisfactory to the examiners, the said board shall issue its certificate in accordance with the facts, and the lawful holder of such certificate shall be entitled to all the rights and privileges herein mentioned.

SECT. II. In case a State Board of Health shall not be established by law, then each State Medical Society incorporated and in active existence on the first day of July, eighteen hundred and seventy-seven, whose members are required to possess diplomas or license from some legally-chartered medical institution in good standing, shall appoint, annually, a Board of Examiners, consisting of seven members, who shall hold their offices for one year, and until their successors shall be chosen. The Examiners so appointed shall go before a county judge and make oath that they are regular graduates or licentiates, and that they will faithfully perform the duties of their office. Vacancies occurring in a Board of Examiners shall be filled by the Society appointing it by the selection of alternates, or otherwise.

SECT. III. The State Board of Health, if such Board of Health shall be established by law, or Board of Examiners, shall organize within three months after the passage of this act; they shall procure a seal, and shall receive through their secretary applications for certificates and examinations; the president of each board shall have authority to administer oaths, and the board take testimony in all matters relating to their duties; they shall issue certificates to all who furnish satisfactory proof of having received diplomas or licenses from legally chartered medical institutions in good standing; they shall prepare two forms of certificates, one for persons in possession of diplomas or licenses, the other for candidates examined by the board; they shall furnish to the county clerks of the several counties a list of all persons receiving certificates. In selecting places to hold their meetings, they shall, as far as is reasonable, accommodate applicants residing in different sections of the State, and due notice shall be published of all their meetings. Certificates shall be signed by all the members of the board granting them, and shall indicate the medical society to which the examining board is attached.

SECT. IV. Said State Board of Health, if such Board of Health shall be established by law, or Board of Examiners, shall examine diplomas as to their genuineness, and if the diploma shall be found genuine as represented, the secretary of the State Board of Health, if such Board of Health shall be established by law, or Board of Examiners, shall receive a fee of one dollar from each graduate or licentiate, and no further charge shall be made to the applicants; but if it be found to be fraudulent, or not lawfully owned by the possessor, the board shall be entitled to charge and collect twenty dollars of the applicant presenting such diploma. The verification of the diploma shall consist in the affidavit of the holder and applicant that he is the lawful possessor of the same, and that he is the person therein named. Such affidavit may be taken before any person authorized to administer oaths, and the same shall be attested under the hand and official seal of such officer, if he have a seal. Graduates may present their diplomas and affidavits as provided in this act, by letter or by proxy, and the State Board of Health, if such Board of Health shall be established by law, or Board of Examiners, shall issue its certificate the same as though the owner of the diploma was present.

SECT. V. All examinations of persons not graduates or licentiates shall be made directly by the board, and the certificates given by the boards shall authorize the possessor to practice medicine and surgery in the State of Illinois.

SECT. VI. Every person holding a certificate from the State Board of Health, if such Board of Health shall be established by law, or Board of Examiners, shall have it recorded in the office of the clerk of the county in which he resides, and the record shall be indorsed thereon. Any person removing to another county to practice shall procure an indorsement to that effect on the certificate from the county clerk, and shall record the certificate, in like manner, in the county to which he removes, and the holder of the certificate shall pay to the county clerk the usual fees for making the record.

SECT. VII. The county clerk shall keep, in a book provided for the purpose, a complete list of the certificates recorded by him, with the date of the issue and the name of the medical society represented by the State Board of Health, if such Board of Health shall be established by law, or Board of Examiners issuing them. If the certificate be based on a diploma or license, he shall record the name of the medical institution conferring it, and the date when conferred. The register of the county clerk shall be open to public inspection during business hours.

SECT. VIII. Candidates for examination shall pay a fee of five dollars, in advance, which shall be returned to them if a certificate be refused. The fees received by the board shall be paid into the treasury of the medical society by which the board shall have been appointed, and the expenses and compensation of the board shall be subject to arrangement with the society.

SECT. IX. Examinations may be made in whole or in part in writing, and shall be of an elementary and practical character, but sufficiently strict to test the qualifications of the candidate as a practitioner.

SECT. X. The State Board of Health, if such Board of Health shall be established by law, or Board of Examiners, may refuse certificates to individuals guilty of unprofessional or dishonorable conduct, and they may revoke certificates for like causes. In all cases of refusal or revocation the applicant may appeal to the body appointing the board.

SECT. XI. Any person shall be regarded as practicing medicine, within the meaning of this act, who shall profess publicly to be a physician and to prescribe for the sick, or who shall append to his name the letters of "M. D." But nothing in this act shall be construed to prohibit students from prescribing under the supervision of preceptors, or to prohibit gratuitous services in cases of emergency. And this act shall not apply to commissioned surgeons of the United States army and navy.

SECT. XII. Any itinerant vender of any drug, nostrum, ointment, or appliance of any kind, intended for the treatment of disease or injury, or who shall, by writing or printing, or any other method, publicly profess to cure or treat diseases, injury, or deformity by any drug, nostrum, manipulation, or other expedient shall pay a license of one hundred dollars a month, to be collected in the usual way.

SECT. XIII. Any person practicing medicine or surgery in this State without complying with the provisions of this act shall be punished by a fine of not less than fifty dollars, nor more than five hundred dollars, or by imprisonment in the county jail for a period of not less than thirty days, nor more than three hundred and sixty-five days, or by both such fine and imprisonment for each and every offense; and any person filing or attempting to file as his own the diploma or certificate of another or a forged affidavit of identification shall be guilty of a felony, and upon conviction shall be subject to such fine and imprisonment as are made and provided by the statutes of this State for the crime of forgery; but the penalties shall not be enforced till on and after the thirty-first day of December, eighteen hundred and seventy-seven: *Provided*, That the provisions of this act shall not apply to those that have been practicing medicine ten years within this State.

[The Board of Health was established by law approved May 25, 1877, which took effect July 1, 1877.]

NEW HAMPSHIRE.

General Laws relating to the Practice of Medicine, Surgery, Dentistry, and Pharmacy.

Chapter I. Practice of medicine, surgery, and dentistry.

Section I. Physicians and surgeons not to practice without license from medical society. SECT. II. Medical societies to examine and license. SECT. III. Dentists not to practice without dental degree or license of New Hampshire Dental Society. SECT. IV. Society shall examine and license. SECT. V. License recorded, where. SECT. VI. Fees for licenses. SECT. VII. Penalty for practicing without lawful authority. SECT. VIII. Law not applicable, when.

Section I. It shall not be lawful for any person to practice medicine, surgery, or midwifery, unless such person shall have obtained a license from some medical society organized under

the laws of this State, stating that he is qualified in the branches of the medical profession named in said license.

SECT. II. Every medical society organized under the laws of this State, shall, at such time and in such manner as may be prescribed in its charter or by-laws, elect a board of censors, consisting of three members, who shall be elected for such term as may be prescribed in said charter or by-laws, which board shall have authority to examine and license persons to practice medicine, surgery, or midwifery.

The board shall issue licenses without examination to all persons who furnish evidence by diploma from some medical school authorized to confer degrees in medicine and surgery, when said board is satisfied that the person presenting such diploma has obtained it after pursuing some prescribed course of study and upon due examination.

Said board shall also have power, upon due notice and hearing, to revoke any license granted by said board, when improperly obtained, or when the holder has, by conviction for crime, or any other cause, ceased to be worthy of public confidence.

Such license or revocation shall be recorded by the clerk of said medical society.

SECT. III. It shall not be lawful for any person who is not duly authorized to practice medicine or surgery to practice dentistry, unless such person has received a dental degree from some college, university, or medical school authorized to confer the same, or shall have obtained a license from the New Hampshire Dental Society.

SECT. IV. Said dental society shall, at such time and in such manner as may be prescribed in its charter or by-laws, elect a board of censors, consisting of three members, who shall be elected for such term as may be prescribed by the society, which board shall have authority to examine and license persons to practice dentistry. The license shall be recorded by the clerk of said society.

SECT. V. No person receiving a license as herein provided shall be authorized to practice until he shall have procured the same to be recorded by the clerk of the court in the county where he resides, if a resident of this State; if not a resident of this State, in the county where he intends to practice.

Such licenses shall be recorded in a book provided for that purpose, and which shall bear the title and inscription of the medical and dental register of — county; and the fee for recording the same shall be fifty cents.

SECT. VI. Each person receiving a license upon examination shall pay for the use of the society granting the same the sum of five dollars; upon diploma one dollar.

SECT. VII. If any person shall practice medicine, surgery, midwifery, or dentistry, without being duly authorized as provided in this chapter, or after his license is revoked, he shall be punished by a fine of not more than three hundred dollars for each offense.

SECT. VIII. The provisions of the preceding sections shall not apply to persons who have resided and practiced their profession in the town and city of their present residence during all the time since January first, eighteen hundred and seventy-five, nor to physicians residing out of the State, when called into the State for consultation with duly licensed physicians, or to attend upon patients in the regular course of business.

Chapter 2. Sale of drugs and medicine.

Chapter 3. Advancement of anatomical and surgical science.

PENNSYLVANIA.

No. 55. An Act to regulate the Practice of Medicine, Surgery, and Obstetrics in the Commonwealth of Pennsylvania.

Section I. *Be it enacted, etc.:* That the standard qualifications of a practitioner of medicine, surgery, and obstetrics, or of any one who may attempt to practice, singly or jointly, medicine, surgery, or obstetrics, shall be and consist of the following, namely:—

A comprehensive and practical knowledge of human anatomy, human physiology, pathology, chemistry, materia medica, obstetrics, practice of medicine and surgery, and public hygiene, and a good moral character.

SECT. II. The possession of a diploma, regularly issued by a medical school acting under a charter from this or other State or country shall constitute the sufficient license for the person to whom such diploma is granted to practice, singly or jointly, medicine, surgery, or obstetrics, as set forth and empowered in said diploma: *Provided, however,* that a diploma that has been or that may hereafter be granted for a money consideration, or other article of value alone, or that has been or may hereafter be granted to any one who has not pursued the usual course of

studies required by a legally chartered medical school, shall not be considered as a sufficient qualification under this act.

SECT. III. Any practitioner who may not have a diploma, as provided for in section two of this act, and who may not be qualified, as hereinafter provided, shall have the privilege of applying to the prothonotary of the court of common pleas of the judicial district in which such applicant resides for an examination in the branches of medical science and art, set forth in section one of this act; whereupon it shall be the duty of such court to appoint a committee or committees, consisting each of three respectable practitioners of medicine of the school of practice recognized in this commonwealth, to which such applicant or applicants may profess to belong, and shall fix the time and place of holding such examinations.

Each of said applicants, before being admitted to examination, shall deposit with such committee the sum of fifteen dollars (\$15), which money shall be equally divided among them, for which they shall give a receipt; it shall be the duty of such committee or committees to convene at any time upon the call of an applicant or applicants for examination; it shall be the duty of such committee, when the said applicant is found to be qualified, as set forth in section one of this act, to grant to such applicant a certificate, and said certificate shall be the sufficient license for the person to whom it is granted to open an office in this commonwealth for the practice of medicine, surgery, or obstetrics; it shall further be the duty of such committee to appear before the clerk of such court and take an oath or affirmation that they have not taken and will not receive, directly or indirectly, any other compensation for instituting such examination than that which is herein provided.

SECT. IV. Any person who has attended one full course of lectures in any respectable school of medicine recognized by law, and has been a resident practitioner of medicine, surgery, or obstetrics in this commonwealth five years previous to the passage of this act, is hereby authorized to pursue the same. Any person who has been in the continuous practice of medicine, surgery, or obstetrics for ten years in this commonwealth shall be and is hereby authorized to pursue the same.

SECT. V. Any person who shall attempt to practice medicine or surgery, by opening a transient office within this commonwealth, or who shall, by handbill or other form of written or printed advertisements, assign such transient office or other place to persons seeking medical or surgical advice or prescription, shall, before being allowed to practice as aforesaid, appear before the clerk of the court of quarter sessions of the county wherein said practitioner shall attempt to practice, and shall furnish satisfactory evidence to such clerk that the provisions of this act have been complied with, and shall, in addition, take out a license for one year, and pay into the county treasury, for the use of such county, the sum of two hundred dollars therefor, whereupon it shall be the duty of such clerk to issue to such applicant a proper certificate of license, on payment of the fee of two dollars for his services: *Provided, however,* that the announcement of name, title, and place of business by card, or announcement of name, title, and place of business in newspaper or other periodical, shall be sanctioned as legitimate, and is so approved by this act.

SECT. VI. Any person violating the provisions of this act shall be deemed guilty of a misdemeanor, and on conviction shall be sentenced to pay a fine not exceeding five hundred dollars, for the use of the county wherein such misdemeanor is committed, or imprisonment not exceeding one year, or both, at the discretion of the court; any person so convicted shall not be entitled to any fee for services rendered, and if a fee shall have been paid, the patient, or his or her heirs, may recover the same as debts of like amount are now recoverable by law.

Approved the 12th day of April, A. D. 1875.

AN ACT TO PROVIDE FOR THE REGISTRATION OF ALL PRACTITIONERS OF MEDICINE AND SURGERY.

Section I. *Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in General Assembly met, and it is hereby enacted by the authority of the same:* That the prothonotary of each county shall purchase a book of suitable size, to be known as the medical register of the county (if such book has not been purchased already), and shall set apart one full page for the registration of each practitioner, and when any practitioner shall depart this life or remove from the county he shall make a note of the same at the bottom of the page, and shall perform such other duties as are required by this act.

SECT. II. Every person who shall practice medicine or surgery, or any of the branches of medicine or surgery, for gain, or shall receive or accept for his or her services as a practitioner of medicine or surgery any fee or reward, directly or indirectly, shall be a graduate of a legally chartered medical college or uni-

versity having authority to confer the degree of doctor of medicine (except as provided for in section five of this act), and such person shall present to the prothonotary of the county in which he or she resides or sojourns his or her medical diploma, as well as a true copy of the same, including any indorsements thereon, and shall make affidavit before him that the diploma and indorsements are genuine; thereupon the prothonotary shall enter the following in the register, to wit: the name in full of the practitioner, his or her place of nativity, his or her place of residence, the name of the college or university that has conferred the degree of doctor of medicine, the year when such degree was conferred, and in like manner any other degree or degrees that the practitioner may desire to place on record, to all of which the practitioner shall likewise make affidavit before the prothonotary, and the prothonotary shall place the copy of such diploma, including the indorsements, on file in his office for inspection by the public.

Sect. III. Any person whose medical diploma has been destroyed or lost shall present to the prothonotary of the county in which he or she resides or sojourns a duly certified copy of his or her diploma; but if the same is not obtainable, a statement of this fact, together with the names of the professors whose lectures he or she attended, and the branches of study upon which each professor lectured, to all of which the practitioner shall make affidavit before the prothonotary, after which the practitioner shall be allowed to register in manner and form as indicated in section two of this act, and the prothonotary shall place such certified statement on file in his office for inspection by the public.

Sect. IV. Any person who may desire to commence the practice of medicine or surgery in this State after the passage of this act, having a medical diploma issued or purporting to have been issued by any college, university, society, or association in another State or foreign country, shall lay the same before the faculty of one of the medical colleges or universities of this Commonwealth for inspection, and the faculty being satisfied as to the qualifications of the applicant and the genuineness of the diploma shall direct the dean of the faculty to indorse the same, after which such person shall be allowed to register, as required by section two of this act.

Sect. V. Any person who has been in the continuous practice of medicine or surgery in this Commonwealth since one thousand eight hundred and seventy-one without the degree of doctor of medicine shall be allowed to continue such practice, but such person shall, nevertheless, appear before the prothonotary of the county in which he or she resides, and shall present to him a written statement of these facts, to which the practitioner shall make affidavit; thereupon the prothonotary shall enter the following in the register, to wit: the name in full of the practitioner, his or her place of nativity, his or her place of residence, the time of continuous practice in this Commonwealth, and the place or places where such practice was pursued, to all of which the practitioner shall likewise make affidavit, and the prothonotary shall place the certified statement on file in his office for inspection by the public.

Sect. VI. Every practitioner who shall be admitted to registration shall pay to the prothonotary one dollar, which shall be compensation in full for registration, and the prothonotary shall give a receipt for the same.

Sect. VII. Any practitioner who shall present to the faculty of an institution for indorsement, or to a prothonotary, a diploma which has been obtained fraudulently or is in whole or in part a forgery, or shall make affidavit to any false statement to be filed or registered, or shall practice medicine or surgery without conforming to the requirements of this act, or shall otherwise violate or neglect to comply with any of the provisions of this act, shall be deemed guilty of a misdemeanor, and on conviction shall be punished for each and every offense by a fine of one hundred dollars, one-half to be paid to the prosecutor and the other half to be paid to the county, or be imprisoned in the county jail of the proper county for a term not exceeding one year, or both, or either, at the discretion of the court.

Sect. VIII. Nothing in this act shall be so construed as to prevent any physician or surgeon legally qualified to practice medicine or surgery in the State in which he or she resides from practicing in this Commonwealth, but any person or persons operating an office or appointing any place where he or she may meet patients or receive calls shall be deemed a sojourner, and shall conform to the requirements of this act.

Sect. IX. This act shall take effect on the first day of June, one thousand one hundred and eighty-one.

The *Medical Times* makes the following comments upon the above law:—

A weak point in this otherwise admirable law is, it appears to us, the fact that no limit of time is fixed for registry beyond which the penalty may be enacted for non-compliance. The act went

into effect on June 1st. Are all practitioners who failed to register on that day liable to fine and imprisonment? Hardly, we should think. But, on the other hand, how long are the ignorant, negligent, and criminally inclined to be permitted to neglect registration? Indefinitely? It looks like it. We venture also to wonder how the prothonotary is to know when any practitioner has "departed this life." Must he scan the daily papers for this purpose? But, on the whole, the act is a good one, and, fraught, we may hope, with advantage to the dignity and respectability of the profession and the health and safety of the community.

TEXAS.

Extract from Civil Code of the State of Texas, adopted by the legislature, to take effect from September 1, 1879.

Title LXXIII. Physicians. Article 3625. The presiding judges of the district courts of the several judicial districts of this State shall, as soon as practicable, severally appoint a board of medical examiners for their respective districts, which appointment shall be in writing and signed by the judge making the same, and delivered to the person appointed.

Art. 3626. Said board of medical examiners shall be composed of not less than three practicing physicians of known ability, who are graduates of some medical college recognized by the American Medical Association, and who are residents of the district for which they are appointed.

Art. 3627. The appointment of a member of a board of medical examiners shall continue for two years from the date of such appointment.

Art. 3628. The board shall, immediately after appointment, select one of their number president and one secretary, and adopt all necessary rules for the guidance and control of their meetings.

Art. 3629. Said board shall meet regularly, semi-annually, at some central point in their respective districts, to conduct examinations and grant certificates as hereinafter provided, and they shall give at least one month's public notice of the time and place of their meeting, by publication in at least one newspaper published in the district in which such meeting is to be held.

Art. 3630. Each and every one of such boards shall procure a seal as soon as practicable after their organization, which seal shall be impressed upon every certificate granted.

Art. 3631. Whenever a vacancy occurs in any of said boards, the same shall be filled by appointment by the judge of the district in which such vacancy occurs.

Art. 3632. It shall be the duty of said board to examine thoroughly all applicants for certificates of qualification to practice medicine in any of its branches or departments in this State, whether such applicants are furnished with medical diplomas or not, upon the following named subjects, to wit: anatomy, physiology, pathological anatomy and pathology, surgery, obstetrics, and chemistry; but no preference shall be given to any school of medicine.

Art. 3633. When the board shall be satisfied as to the qualifications of an applicant, they shall grant him a certificate to that effect, which certificate shall entitle the person to whom granted to practice medicine in any county in this State, when the same has been recorded as required by Article 3635.

Art. 3634. Any two of the members of such board of medical examiners may grant a certificate of qualification to an applicant, and any member of said board shall have authority to grant a temporary certificate to an applicant upon examination until the next regular meeting of the board, at which time the temporary certificate shall cease to be of force.

Art. 3635. The certificate provided for in the two preceding articles shall, before the person to whom it is granted is entitled to practice by virtue thereof, be recorded in the office of the clerk of the county court of the county in which such practitioner may reside or sojourn, in a well-bound book to be kept by the clerk for that purpose; and when so recorded the clerk shall certify thereon under his official seal the fact and date of such record, and shall return such certificate to the person to whom the same was granted, and shall be entitled to demand and receive for such service, from the holder of such certificate, the sum of one dollar.

Art. 3636. The board shall be entitled to demand and receive from each applicant examined the sum of fifteen dollars, whether a certificate be granted to such applicant or not.

Art. 3637. The provisions of this title shall not apply to the following persons: (1.) To those who may have been already qualified for the practice of medicine under an act entitled An Act to regulate the Practice of Medicine, passed May 16, 1873. (2.) To those who have been regularly engaged in the general practice of medicine in this State or in any of its branches or

departments for a period of five consecutive years prior to the first day of January, 1875. (3.) To females who follow the practice of midwifery strictly as such.

Art. 3638. No person, except those named in the preceding article, shall be permitted to practice medicine in any of its branches or departments in this State without having first obtained and recorded a certificate of qualification from some authorized board of medical examiners, as hereinbefore provided; and any person so offending shall be punished as provided in the Penal Code.

Extract from the Penal Code of the State of Texas:—

Title XII. Chapter three. Unlawful Practice of Medicine.

Article 396. If any person shall practice medicine in this State in any of its branches or departments, or offer or attempt to practice, without first having obtained a certificate of professional qualification from some authorized board of medical examiners, he shall be punished by a fine of not less than fifty nor more than five hundred dollars.

Art. 397. Each patient visited or prescribed for, or each day's offer to practice, shall constitute a separate offense under the preceding article.

Art. 398. If any person shall hereafter engage in the practice of medicine in any of its branches or departments, without having first filed for record with the clerk of the district court of the county in which such person may reside or sojourn a certificate of professional qualification from some authorized board of medical examiners, he shall be punished as prescribed in Article 396.

Art. 399. The provisions of this chapter shall not apply to any person who has been regularly engaged in the general practice of medicine, or in any of its branches or departments in this State, for five consecutive years prior to January 1, 1873; nor to any person who may have legally qualified himself to practice medicine under the provisions of an act entitled, Act to regulate the Practice of Medicine, passed May 16, 1873; nor to any female who may follow the practice of midwifery strictly as such.

Adopted and went into effect on September 1, 1879.

Medical Schools.

THE NEW YORK AND BROOKLYN MEDICAL SCHOOLS.

COLLEGE OF PHYSICIANS AND SURGEONS, MEDICAL DEPARTMENT OF COLUMBIA COLLEGE.

THE important changes announced at this college continue in operation. The spring session was then discontinued, and all the exercises of the school henceforth take place during one continuous session; so that, instead of a spring session and a succeeding winter session of five months' length, which formerly made up the collegiate year, this, since the collegiate year of 1880-81, consists of a single session of somewhat over seven months in length, which will commence upon the 3d of October and end during the first part of May. The only intermissions in the lectures will be for three days at Thanksgiving and one week at Christmas. Thus, for a "required" session of five months and an "optional" session of two and a half months, there is now substituted a "required" session of seven months. This session is not merely an extension of the winter session, with the same amount of stated exercises per week; but the number of didactic and other stated exercises each week has been diminished, at the same time that the course has been lengthened, for the purpose of allowing more time for laboratory and hospital work, recitations, and private study. This the faculty regards as a very valuable change, since, until last year, owing to the shortness of the session, the student's day was too crowded, for his good, with stated exercises.

The omission from the scheme of exercises of several didactic lectures a week will render it possible for the recitations conducted by the corps of exam-

iners to be held almost entirely during the daytime instead of in the evening, as previously.

After the first of May, beginning immediately at the close of the course of lectures, the examinations will occur, and the commencement exercises will henceforth be held about the middle of May, instead of at the end of February. As has been the case for some time at this school, all the examinations for the degree of M. D. will be conducted entirely in writing, and no candidate will be allowed to graduate until he shall have passed a satisfactory examination in each and all of the seven branches. The candidate is "conditioned" when the average merit of his thesis and examinations has been satisfactory, while in one or more branches he has been found deficient; in which case he can proceed to his degree only on the condition that he first pass a re-examination in the deficient branch or branches, not sooner than at the next regular semi-annual examination. The candidate is "rejected" when the average merit of his thesis and examination has been unsatisfactory, and in this case he must be re-examined in all the seven branches, although the writing of a new thesis is rarely required.

The college authorities state that the prospects of the institution were never better than at present. The usual prizes are announced, and the award of the Alumni Association Prize will be made at the commencement, 1882. The next award of the Stevens Triennial Prize, which is open for universal competition, but which is given to no essay which does not include the results of original research, will be made in 1882, and the subjects (of which either may be chosen) are as follows:—

- (1.) Lesions of the Brain in Connection with the two Forms of Diabetes.
- (2.) Diphtheria in its Relations to Membranous Croup.

BELLEVUE HOSPITAL MEDICAL COLLEGE.

The changes announced in the curriculum at this school consist mainly of a renunciation of the attempt at an *obligatory* course of three full sessions at the college, and of a return to the optional three years' course.

The faculty stated last year that for several years they had endeavored to induce students to attend three courses of lectures (passing their examinations in the elementary departments at the close of the second session), and that those who had followed this course had shown in their examinations a grade of qualification much higher than the standard usually attained by students under the old system.

The experience of the session of 1880-81 has led the faculty reluctantly to the conclusion that to persist in the requirement of attendance during three courses will be to incur a risk as regards the interests of the college, which they do not feel justified in assuming.

In announcing a return to their original requirements for graduation, the faculty desire to state that all the new additions to the curriculum will be retained. It is not proposed to recede in the least from these. Students will have the same opportunities for practical exercise in the different departments as those enjoyed by the class of 1880-81. For those who choose to attend during three sessions, the provisions as respects examinations in the elementary branches at the end of the second year, and an exclusive devotion to the practical departments during the third year, will be continued. To all students who are able to do

so, now, as hitherto, attendance during three years is strongly recommended; and from the number of those who have already matriculated with the expectation of attending three sessions, the faculty entertain a belief that not an inconsiderable proportion of future classes will voluntarily follow their example.

For the session of 1881-82, the requirements for graduation will be three years' pupilage, after eighteen years of age, and attendance upon two full courses of lectures, of which one course must be at the Bellevue Hospital Medical College.

The ordinary matriculation examination will consist of English composition, grammar, arithmetic (including vulgar and decimal fractions), algebra (including simple equations), and geometry (first two books of Euclid); but this examination will be waived in the case of those who have received the degree of A. B., those who have passed the freshman examination for entrance into any incorporated literary college, those who present certificates of proficiency in the subjects of the matriculation examination from the principal or teachers of any reputable high school, and those who have passed a matriculation examination at any recognized medical college, or at any scientific school or academy in which an examination is required for admission.

Students are expected to attend all the lectures, including clinics, for the first two years. During the third year they should attend all the clinics, but they may confine their attendance upon the didactic lectures to the branches upon which they are to pass their final examinations; by which means time can be obtained for practical work in the dissecting-room and the chemical and pathological laboratories, and for practical clinical exercises in medicine, surgery, and gynecology. Students are expected to attend regular weekly recitations, held by members of the faculty during each session, in the branches upon which they are to be examined at the close of the session, and for those who attend the full course of instruction at the college for three years the regular examinations at the close of each of the three sessions are obligatory.

Clinical instruction, in connection with the regular didactic courses, will remain as the distinguishing feature of the curriculum, beginning with the first course and continuing without interruption during the entire three years; and great advantages are claimed in this respect on account of the large amount of material at the command of the lecturers. The faculty remains substantially unchanged this year, and there will be the regular winter and spring sessions as heretofore.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

The University school continues its policy of endeavoring to keep its various departments as fully as possible up to the most modern ideas and methods of teaching and practice. Its building, which was erected at a cost of \$110,000, is the newest of any of the medical colleges, and is fitted up with the most approved appliances for instruction and practical study; while it has the same advantage as the Bellevue School of proximity to the great Bellevue and Charity hospitals. The comfort and health of the students are also a matter of solicitude on the part of the faculty, who do all that they can to secure to them "sound minds in sound bodies." The system of weekly examinations by the various professors, which was established four years

ago, has produced such good results in improving the preparation of the students for their work that they will be continued during this winter; while the method of written examinations for the degree of M. D. has been found to be so satisfactory both to the students and the professors that it is now adopted in all the departments. It is believed that this gives the student a much better opportunity to do justice to his knowledge than the plan of oral examinations. With a view to the establishment of a systematic, graduated scheme of tuition, students who have attended two full courses of lectures, and who have completed two years of study, may be admitted to examination in chemistry, anatomy, and physiology, and if successful, will be examined in practice, materia medica and therapeutics, surgery and obstetrics, at the expiration of their full course of study; but those who prefer it may have all their examinations at the close of their full term.

In order to stimulate the efforts of the students, three prizes, in addition to the Mott medals, are to be given by the faculty at the close of the present session, namely:—

I. A prize of five hundred dollars to the candidate whose general scholastic standing is the highest, as shown by the record of his final examination for the degree of M. D.

II. A prize of three hundred dollars to be awarded to the candidate who shall pass the best competitive examination in the seven general departments.

III. A prize of two hundred dollars will be awarded to the candidate who shall pass the second-best examination in the above competition.

The conditions being as follows:—

(1.) Each competitor must have attended two or more full courses of lectures in the University.

(2.) The faculty will select from the graduating class ten candidates, whose marks for the degree are the highest, and only these will be permitted to enter into the competition.

(3.) These examinations shall be conducted in public, and they may be oral or written, at the discretion of the faculty.

(4.) The candidate who receives the first-named prize for general scholastic standing shall not be allowed to compete for this prize or the following.

The collegiate year is divided, as before, into three sessions,—the spring session, the preliminary winter session, and the regular winter session,—the whole embracing a period of about seven and a half months. The spring session is devoted to clinical teaching, lectures on various "specialties," and recitations, and it extends for nearly three months after the close of the winter session; while the preliminary winter session occupies the two weeks preceding the opening of the regular session. The lectures in this term, both clinical and didactic, are the same in number and order as during the winter session, and are given by the professors of the regular and post-graduate faculties; the subjects of the lectures being introductory to those of the regular course. The post-graduate course consists of clinical lectures delivered during the winter and spring sessions by the several professors of the post-graduate faculty, in Bellevue and Charity hospitals and in the college.

LONG ISLAND COLLEGE HOSPITAL, BROOKLYN.

The faculty of this institution have carried out many changes during the last few years, and it is claimed that great progress has been made, so that the

course of study is believed to be as complete as any in the country. "In the Long Island College Hospital," says Prof. Jarvis S. Wight, in a late introductory lecture delivered at the school, "we divide our class of advanced students into as many sections as we have practical departments. One section is drilled one week in one department, and another week in another department, and so on through all the departments again and again. In the mean time every other section is going through the same process of rotation. The stethoscope and the tape-line are put into the hands of the student. He listens and measures; he studies the clinical facts of medicine and surgery on the living subject; and day after day he works the substance of these facts into his mental constitution. He observes, he thinks, he educates himself, — and this is the way doctors are made in these halls. In this place there is no royal road to the profession, any more than there is a royal road in the profession. And when men who have been well drilled in this kind of clinical medicine come up for their final examination we find that they have their professional house built on a rock, and that their work after they leave this place is honorable, salutary, and safe. . . . We have established a three years' course of recitations and lectures. During one half of the collegiate year the student is drilled in the elements of medicine by competent teachers. During the other half of the collegiate year the student hears lectures and is daily examined on what he learns. And when the student has mastered the elements of medicine he is taught clinical medicine in the way already described. This simple and efficient plan of instruction has been in operation in this school for a number of years. The success has been very encouraging. We began this system with only about five students. The number has increased from year to year, until we have now about fifty students pursuing a systematic three years' course of study."

The Long Island College Hospital was organized for the purpose of practically uniting a hospital and a medical school, and the founders have matured the plan and practically carried it out to an extent which they believe is unequalled by any other school in this country. The success of this plan, it is thought, depends mainly on two important factors: —

(1.) The hospital is under the immediate control of the regents and council of the college, and is therefore available at all times for practical instruction.

(2.) The courses of instruction are given in the hospital building, so that the student, without loss of time, is brought in direct contact with the patients.

The faculty claim that they are "thus able to make clinical teaching a *reality* in the only possible way in which it can be of practical value to the student, namely, by cultivating his faculties of observation *at the bedside*. Mere amphitheatre teaching must, from the very nature of clinical study, fail to accomplish work that can only be done in the wards of a hospital."

The collegiate year embraces a reading and recitation term (which begins this year September 28th), and a regular session (which begins January 25, 1882) and continues five months; but only the regular session is obligatory upon candidates for graduation. The students of the reading term are classified in three grades, each grade corresponding to one year's study.

Grade 1. Students who have studied one year, and attended the full reading and regular sessions, may be admitted to the regular examination on elementary

chemistry, osteology, normal histology, and materia medica.

Grade 2. Students who have attended both courses for two full years may be admitted to such of the above examinations as they have not already passed, and also to examination on descriptive anatomy, physiology, therapeutics, analytical chemistry, and general pathology.

Grade 3. Students who have passed successfully the examinations of grade one and two shall belong to the third grade. About one half the students now attend this full three years' graded course; but it is the intention of the council and faculty to make this course (which is at present voluntary and elective for the student) at an early period a *requirement* for graduation.

For the purpose of carrying out more fully the objects of clinical instruction, and thereby perfecting the system of *demonstrative* teaching, the faculty have adopted the plan of dividing the senior class into sections of ten or more, who accompany the clinical teacher in his daily hospital service; and by this plan of constant rotation of classes from the medical to the surgical wards of the hospital they believe that the student receives the largest possible amount of instruction daily in all the practical branches. This mode of teaching, it is claimed, is peculiar to the Long Island College Hospital. The faculty also adhere to daily class examinations, having found by experience that the plan of constant class-room drill encourages exact knowledge and habits of close attention; while in its practical results it is superior to the system of lectures alone.

The registrar of the college writes, "The outlook for our school is better to-day than ever before. We mean real reform in medical education, and time will vindicate us."

MEDICAL DEPARTMENT OF THE UNIVERSITY OF BUFFALO.

THE regular term begins the first week in October and continues twenty weeks.

In the plan of instruction adopted in this institution, clinical teaching occupies an important and prominent position; the practical subjects presented in the didactic course being fully illustrated at the bedside. The Buffalo Hospital of the Sisters of Charity, and the Buffalo General Hospital, together with the cases presented at the college, furnish ample material for clinical instruction. In this respect few, if any, institutions in the country possess equal advantages. — equal, at least, in point of availability, since arrangements have been made by which all the clinical cases can be *seen* and *studied* by the class.

The following are the requisites for graduation: —

The didactic lectures are given in the college edifice, situated on the corner of Main and Virginia Streets. This is a commodious stone structure, conveniently and pleasantly situated, constructed with express reference to medical instruction, containing two large lecture rooms, museum, chemical apparatus, laboratory, etc., exclusively devoted to the Medical Department of the University.

In connection with the medical cases of the hospital, as well as in the didactic course of the college, particular attention will be paid to the subject of physical exploration.

The Buffalo Hospital of the Sisters of Charity is a large and modern institution; the professors in the college are the attending medical officers of the hospital during lecture session.

Twenty-one years of age; a good moral character; satisfactory evidence of having studied medicine for three years under the tuition of a regular practitioner or practitioners; dissection during one course, either at this or some other incorporated institution; two full course of lectures, the last having been at this institution, are the requisites for graduation

MEDICAL SCHOOLS OF PHILADELPHIA.

AMONG the world's great medical centres of modern times Philadelphia has for many years occupied an important and influential position. More than twenty thousand physicians have graduated in that city. To Philadelphia belongs the honor of having established the first medical school upon this continent. In 1765 the Medical Department of the University of Pennsylvania was organized by Drs. John Morgan and William Shippen, under the authority of the board of trustees of the university and the recommendation of the proprietary of the State. It was closely modeled upon the methods pursued at the University of Edinburgh, the trustees declaring that "their scheme of medical education was to have as extensive and liberal a plan as in the most respectable European seminaries, and that the utmost provision was made for rendering a degree a real mark of honor, the reward only of distinguished learning and abilities." In order to show how sincere were these strivings for higher medical education we quote the requirements that were then thought essential in order to obtain the degree of doctor in medicine. It was enacted "that all such students as have not taken a degree in any college shall, before admission to any degree in physic, satisfy the trustees and professors of the college concerning their knowledge of the Latin tongue, and in such branches of mathematics, natural and experimental philosophy, as shall be judged requisite to a medical education." Two grades of degrees in medicine were established. For the lower of these, that of bachelor of medicine, the student was required to serve a sufficient apprenticeship with some reputable physician; to have a general knowledge in pharmacy; to attend at least one complete course of lectures, and to follow the practice of a general hospital for one year. After having shown his fitness at a private examination, he was then admitted to a public examination for the bachelor's degree. To obtain the degree of doctor of medicine it was necessary that the applicant should have been a bachelor of medicine for at least three years, should have attained the age of twenty-four years, and should write and defend a thesis publicly in the college.¹

Owing to many circumstances beyond the control of the trustees and faculty, or the pressure of circumstances too powerful to be successfully resisted, the requirements for the degree in medicine, in the course of years, were gradually made less stringent by the authorities, but they have always succeeded in maintaining a relatively high standard among medical schools

of this country for the Medical Department of the University of Pennsylvania. In 1876 the term of study was extended from two years to three, and the course was graded. At the last session a further reform and great step in advance was made by reestablishing the preliminary examination, or requiring in lieu thereof the presentation of a certificate of graduation or an academical degree, as an evidence of fitness for entering upon the medical studies.

Jefferson Medical College was chartered in 1825, as the Medical Department of Jefferson College at Canonsburg, Penn. It has long outlived the parent institution, but continues to flourish under its university charter, the right to which it usually asserts once a year by granting honorary degrees of doctor of divinity, and more rarely of doctor of laws, to distinguished individuals recommended by the board of trustees, but no honorary degree in medicine is ever granted by Jefferson College, upon the occasion of the annual commencement. Jefferson College for many years has been in a most flourishing condition, and claims to have at the present time a larger number of living graduates than any other college in the country, and certainly has a larger number of students now in attendance upon the lectures than any other American college.

Both of the above-named institutions have large general hospitals connected with them which are well adapted to their purpose, commodious, clean and well ventilated, and furnished with the latest appliances for the treatment of the sick and maimed and for clinical teaching. In all, Philadelphia has twenty hospitals and at least ten dispensaries, and thirty-eight other charitable institutions with which infirmaries are connected; many of these are devoted to specialties. Before considering the curriculum of the schools more in detail, it is proper to devote some attention to the Pennsylvania Hospital, which has served a highly useful purpose, and taken an honorable part in the history and development of medical education in this country. In 1751, through the persistent efforts of some charitably disposed citizens, a charter was obtained from the proprietary for a hospital for "the sick poor and the reception and cure of the insane," which was opened in this city in 1752. This institution has always been characterized by the economical management of its funds, and the faithfulness of the officers charged with the administration of its important trusts. Upon its staff have been some of the most prominent physicians and surgeons in Philadelphia. Early in its existence the clinical material found in the wards was utilized for the benefit of science. Attracted to the hospital by its growing reputation, even before the establishment of the medical department of the university, students were found in attendance upon the practice of the house. Dr. John Pethergill presented, in 1762, a medical book to the hospital "for the benefit of the young students in physic, who may attend under the direction of the physicians;" this book afterwards was the nucleus of a library, which is now one of the great medical libraries of this country, the Medical Library of the Pennsylvania Hospital. The hospital, before the establishment of the regular schools, took "apprentices," as they were called, and subsequently gave them a certificate of attendance upon the practice of the house. At the present time free medical and surgical clinics are held twice a week for students from the University and Jefferson colleges and physicians, on Wednesday and Saturday from ten to twelve o'clock, and

¹ From an Address on Higher Medical Education the True Interest of the Public and of the Profession. By William Pepper, Professor of Clinical Medicine, University of Pennsylvania. Philadelphia 1877.

there is also a clinic to female students from the Woman's College, on Tuesday mornings throughout the winter session at the college. The insane department of Pennsylvania Hospital stands among the first of institutions of its kind. Its two large buildings are situated in about forty acres of ground in the western part of the city, and are under the care of Dr. Kirkbride and his able assistants.

The medical schools of Philadelphia at present are that of the University of Pennsylvania, Jefferson College, and the Woman's Medical College of Pennsylvania. The schools devoted to special departments of medicine are the Philadelphia School of Anatomy, the Pennsylvania School of Anatomy, the Philadelphia College of Pharmacy, the Pennsylvania College of Dental Surgery, the Philadelphia Dental College and School of Oral Surgery, and the Dental Department of the University of Pennsylvania. At the Nurse's Home, or, as it is technically styled, The Philadelphia Lying-In Charity and Nurse Society, besides the training of nurses, two very practical courses of illustrated lectures on midwifery are given during the winter by the principal physicians, Drs. J. G. Allen and Albert H. Smith.

At the hospital connected with the Woman's Medical College there is an admirable training-school for nurses. In considering the opportunities for special instruction, it should not be forgotten that daily clinics are held at the Will's Eye Hospital; and at the Philadelphia Orthopaedic Hospital and Infirmary for Nervous Diseases clinics are regularly held by the attending physicians and surgeons.

THE UNIVERSITY OF PENNSYLVANIA.

The University of Pennsylvania occupies over twenty acres of elevated ground upon a commanding site in West Philadelphia, one half of this ground being devoted to the medical department; it has situated upon it the Hall of the Department, the Laboratory Building, and the University Hospital. The architecture is modern and harmonious in design, and appropriate and attractive in appearance. The following is the *personnel* of the faculty as at present constituted:—

William Pepper, M.D., LL.D., Provost of the University and *ex officio* President of the Faculty; Henry H. Smith, M.D., Emeritus Professor of Surgery; Joseph Leidy, M.D., LL.D., Professor of Anatomy; Richard A. F. Penrose, M.D., LL.D., Professor of Obstetrics and Diseases of Women and Children; Alfred Stillé, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine; D. Hayes Agnew, M.D., LL.D., John Rhea Barton Professor of Surgery and of Clinical Surgery; William Pepper, M.D., Professor of Clinical Medicine; William Goodell, M.D., Professor of Clinical Gynecology; James Tyson, M.D., Professor of General Pathology and Morbid Anatomy; Horatio C. Wood, M.D., Professor of Materia Medica, Pharmacy, and General Therapeutics; Theodore G. Wormley, M.D., LL.D., Professor of Chemistry; John Ashhurst, Jr., M.D., Professor of Clinical Surgery; Harrison Allen, M.D., Professor of Physiology. Professor James Tyson, M.D., is the Secretary of the Faculty.

The curriculum of the graded course is arranged as follows:—

First year. Anatomy, Histology, Materia Medica and Pharmacy, General Chemistry, Physiology, General Pathology, General Clinics—Medical and Surgical. Final examinations at the end of the course: General Chemistry, Materia Medica, and Pharmacy.

Second year. Anatomy, Topographical Anatomy, Medical Chemistry, Physiology, General Pathology and Morbid Anatomy, Therapeutics, Theory and Practice of Medicine, Surgery, Obstetrics, General Clinics—Medical and Surgical. Final ex-

aminations at the end of the course: Anatomy, Medical Chemistry, and Physiology.

Third year. General Pathology and Morbid Anatomy, Topographical Anatomy, Therapeutics, Theory and Practice of Medicine, Surgery, Obstetrics, Operative Surgery, Minor Surgery and Bandaging, Diseases of Women and Children.

Opportunities for practical work in the physiological laboratory will be afforded to those who desire them. A separate fee is charged.

Gynecology, Bedside Instruction in Practical Medicine (including Physical Diagnosis), Bedside Instruction in Practical Surgery, Practical Ophthalmology, Practical Otolaryngology, Practical Dermatology, Practical Electro-Therapeutics, General Clinics—Medical and Surgical. Special Clinics (Nervous Diseases, Diseases of Skin, Eye, Ear, Diseases of Women and Children).

Final examinations for degree at the end of the course: General Pathology and Morbid Anatomy, Therapeutics, Theory and Practice of Medicine, Surgery, Obstetrics, and Diseases of Women and Children.

No beneficiary students are received at the University of Pennsylvania, nor is the secretary at liberty to receive students at reduced rates, except in the case of the six successful applicants for the scholarships created by the board of trustees. These are open to competitive examination by applicants, provided, (1) that they are able to furnish satisfactory evidence that they are without the means to defray the expenses of a medical education; (2) to write a brief autobiography, not exceeding a page of foolscap, which will serve as a test of their qualifications in orthography and grammar; and (3) to pass an examination in a Latin prose translation (first three books of *Cæsar*), and an examination in elementary physics. This examination is held annually in September.

The faculty express great satisfaction with the results of the lengthening of the term and grading the course; it is claimed that the students are better taught, they seem of a higher order of intelligence, and finally that the classes are increasing rather than diminishing in members. The faculty have also established a post-graduate course, which embraces Practical Physiology, taught by Dr. Edward T. Reichert; Medical Chemistry, by Professor Wormley; Pathology, by Dr. H. F. Formad; Clinical Medicine, by Professor Pepper and Dr. Edward T. Bruen; Clinical Medicine, by Professor Tyson; Clinical Surgery, by Professor Ashhurst; Clinical Surgery of Children, by Professor Ashhurst and Dr. H. R. Wharton; Operative Surgery and Bandaging, by Dr. C. T. Hunter; Practical Obstetrics, by Dr. Elliot Richardson; Clinical Gynecology, by Dr. B. F. Baer; Diseases of the Nervous System, including Electro-Therapeutics, by Dr. Charles K. Mills; Diseases of Children, by Dr. John M. Keating; Diseases of Children (Children's Hospital), by Dr. Louis Starr; Ophthalmology, by Dr. S. D. Risley; Dermatology, by Dr. A. Van Harlingen; Otolaryngology, by Dr. W. M. L. Zeigler; Laryngoscopy, by Dr. Carl Seiler; and Venereal Diseases, by Dr. J. William White. A fee ranging from fifteen to twenty-five dollars is charged for instruction in each of these special departments. The Laboratory Building is a spacious building of four floors, the first being devoted to operative dentistry; the second and third are fitted up as chemical laboratories; while the fourth contains apartments for physiological, histological, and pathological investigation. There is also a pharmaceutical laboratory, and one of experimental therapeutics, supplied with the usual instruments for recording pathological conditions and the effects of medicines upon the system. The attendance of the students upon the laboratory courses is compulsory. Before commencing dissecting the student is obliged to attend the osteo-syn-desmological laboratory, in order to

make himself familiar with the bony skeleton before operating upon the cadaver.

(1.) For admission to the session of 1880-1881, the candidate will be required to pass the preliminary examination. Students may report to the secretary for examination at any time after the second Monday in September.

(2.) Students who have attended one course in a regular medical school will be admitted as students of the second course in the University of Pennsylvania, after having satisfactorily passed an examination in general chemistry and materia medica and pharmacy. Students who have attended two courses in a regular medical school shall be admitted as students of the third course in this institution, after having satisfactorily passed an examination in general and medical chemistry, materia medica and pharmacy, anatomy, and physiology.²

Graduates of other regular medical schools in good standing will be admitted as students of the third course without an examination.

Graduates of colleges of pharmacy and dental colleges in good standing are admitted to the second course without an examination.

(3.) The candidate for the degree of doctor of medicine must have attained the age of twenty-one years, and be of good moral character. He must have applied himself to the study of medicine for three years, and have attended at least his last course of instruction in this school; have prepared a satisfactory thesis,³ and have passed the required examinations.

(4.) When a candidate applies to the secretary of the faculty for examination, he must give satisfactory evidence that the above rules have been complied with.

(5.) Candidates who have not been successful upon a first examination will be permitted to have a second before the June commencement.

(6.) The candidate shall pay the graduation fee on the presentation of his thesis, or before receiving notice of having successfully passed his final examination. Upon receiving such notice, he will enter his name on the register for the purpose of being reported to the board of trustees.

(7.) Candidates who have passed their examination, and in other respects complied with the regulations, are reported by the secretary of the faculty to the provost of the university, who communicates such report to the board of trustees, in order that, if approved by them, their mandamus may be issued for conferring the degree.

(8.) The Commencement for conferring the degree of doctor of medicine is held on the 15th day of March, unless that day should fall on a Saturday or Sunday, when it is held on the preceding Friday.

(9.) The degree will not be conferred upon a candidate who absents himself from the public Commencement, except by special permission of the medical faculty.

In regard to the arrangement of sessions, the announcement is as follows:—

The winter session, upon which alone attendance is obligatory, begins on Monday, the 3d day of October, and ends on the last day of February ensuing.

The preliminary session begins on the second Monday in September, and ends on the Saturday preceding the day of opening of the winter session.

The spring session begins the latter part of March and ends about the middle of June.

The entire college expenses for the three years' course is \$115, including matriculation and graduating fees.

JEFFERSON MEDICAL COLLEGE.

The buildings of Jefferson College are situated in the central part of the city (near Tenth and Walnut Streets), and consist of a medical hall, a new laboratory building, and a new hospital.

¹ Homeopathic and eclectic schools are not recognized as being in this category.

² These examinations for admission to advanced standing are held towards the close of September.

³ The thesis must be in the candidate's own handwriting, and shall be written on thesis paper, the alternate pages being left blank. It is recommended that the candidate prepare his essay before the commencement of the last course of lectures. It should also be bound. A title may be published by the candidate if he desires it, the permission of the professor by whom he was examined thereon having been first obtained; but no alteration shall be made in such thesis without the consent of the said professor.

The medical hall contains two large lecture rooms, each capable of seating over six hundred students; they are spacious, well lighted and ventilated. A valuable anatomical, surgical, and pathological museum, rooms for practical pharmacy and experimental therapeutics, as well as the private rooms for offices for the faculty, are also included in this building. The laboratory building is immediately adjoining the medical hall, and communicates directly with it. The first floor is devoted to chemical and philosophical apparatus, the second to laboratory teaching of chemistry, and the third to demonstrations of experimental physiology and microscopy. It also contains a large room for operative and minor surgery. The different departments are all efficiently equipped for scientific work.

The new hospital of the Jefferson Medical College is situated immediately west of the college, fronting on Sanson Street, and is bounded on three sides by streets, and by a wide private passage-way on the fourth side. It is one hundred and seven feet square, five stories in height, and is designed for the easy accommodation of one hundred and twenty-five patients. In connection with the hospital is the out-door or dispensary department, which furnishes much valuable material for clinical instruction.

The faculty of the college comprises the following professors: Joseph Pancoast, M. D., general, descriptive, and surgical anatomy (*emeritus*); Samuel D. Gross, M. D., LL. D., D. C. L. Oxon., LL. D. Cantab., institutes and practice of surgery; Ellerslie Wallace, M. D., obstetrics and diseases of women and children; J. M. Da Costa, M. D., practice of medicine; William H. Pancoast, M. D., general, descriptive, and surgical anatomy; Robert E. Rogers, M. D., medical chemistry and toxicology; Roberts Bartholow, M. D., materia medica and general therapeutics; Henry C. Chapman, M. D., institutes of medicine and medical jurisprudence. Professor Wallace is the dean of the faculty. Prof. William Thompson, M. D., is the ophthalmic surgeon of the hospital; William S. Forbes, M. D., is demonstrator of anatomy; J. Ewing Mears, M. D., demonstrator of surgery; J. Gibbons Hunt, M. D., demonstrator of histology; G. Mason Ward, M. D., demonstrator of chemistry; Morris Longstreth, M. D., demonstrator of pathological anatomy, and curator of the hospital museum; and A. P. Brubaker, M. D., has been appointed demonstrator of physiology, and curator of the anatomical museum.

The requirements for graduation are as follows:—

I. The candidate for the degree of M. D. must be of good moral character, and at least twenty-one years of age. He must have attended at least two full winter sessions of lectures, one of which, the last, shall have been in this college, and must exhibit his tickets, or other adequate evidence of attendance, to the dean of the faculty.

He must have studied medicine for not less than three years, and have attended at least one course of practical anatomy and of clinical instruction. He must present to the dean of the faculty a thesis of his own composition, correctly written, and in his own handwriting, on some medical subject, and exhibit to the faculty, at his examination, satisfactory evidence of his professional attainments.

II. Students who have attended one complete course in a respectable medical school, where attendance on two complete courses is necessary to a degree, and where the same branches are taught as in this, are permitted to become candidates by an attendance here on one full course, the rules of graduation being in other respects observed. They are also exempted from the payment of fees upon attending a second term.

Students of dental colleges, where a five months' winter session is held, and where full courses are given on anatomy, materia medica, physiology, and chemistry, may become candidates after attendance on two courses at such colleges, and one full course at the Jefferson Medical College, with two courses on surgery, practice of medicine, and obstetrics.

Students of colleges of pharmacy, where full courses are given on materia medica and chemistry, may become candidates after attendance on two courses at such colleges, and one full course at the Jefferson Medical College, with two courses on anatomy, surgery, practice of medicine, physiology, and obstetrics.

III. Students who have attended two full courses on anat-

omy, chemistry, materia medica, or institutes may be examined on any of these branches, at the end of their second course. They are thus enabled to devote their last (third) course to the didactic lectures on the remaining branches, and to clinical study. The faculty record with satisfaction the large and increasing number of students who now avail themselves of these examinations, and who attend three courses of lectures before presenting themselves as candidates for graduation. The attendance upon the summer course of lectures has also greatly increased in numbers, and the faculty earnestly recommend all who have it in their power to use these improved facilities for a complete medical education.

No honorary degrees in medicine are granted.

IV. The degree will not be conferred upon any candidate who absents himself from the public Commencement without the special permission of the faculty.

Fee to each professor, twenty dollars, in all, one hundred and forty dollars. Matriculation fee five dollars, to be paid once only. Graduation fee thirty dollars. Students who have paid for two full courses are entitled thereafter to attend free of all charge.

V. Students who have attended two full courses of lectures in other accredited medical colleges are entitled to the tickets of a full course in the Jefferson Medical College for seventy dollars. Graduates of three years' standing of other accredited medical colleges are required to pay the matriculation fee only; to graduates of less than three years' standing the fee for a general ticket is fifty dollars. To graduates of accredited dental colleges and colleges of pharmacy the fee for a general ticket is one hundred dollars.

A preliminary course of lectures is given in September, the regular term commencing annually with the first week in October, and continuing until the close of the third week in March following. There are several courses of special instruction which should be mentioned. The demonstrator of anatomy and the demonstrator of surgery each give two illustrated lectures a week in the evening during the winter, spring, and fall sessions. The large anatomical rooms are open daily from eight A. M. to ten P. M.; a full supply of material is furnished at the rate of one dollar per part.

The working laboratory for practical chemistry, under the supervision of the professor of chemistry, aided by the demonstrator of chemistry, is open twice a week during the winter and spring courses. The student is here taught to manipulate for himself in the preparation of gases, acids, salts, etc., and to test and trace reactions, to perform qualitative and quantitative analysis, to examine normal and abnormal products, and to become familiar with those instruments, such as the microscope, the galvanic battery, etc., which are useful in the hands of the medical practitioner. In connection with this the demonstrator, Dr. G. M. Ward, holds weekly examinations upon the didactic lectures by the professor of chemistry. The fee for the courses is five dollars, and for the use of apparatus and chemicals one dollar and a half. The laboratory which pertains to the chair of physiology is under the immediate charge of a demonstrator, who conducts vivisections and assists advanced students in original investigation. The microscopic laboratory is amply provided with microscopes and other appliances for thorough practical instruction, and is under the charge of Professor J. Gibbons Hunt, demonstrator of histology.

Lectures upon pathological anatomy are given by Dr. Morris Longstreth, pathologist to the hospital, who also gives instruction in the post-mortem rooms of Pennsylvania Hospital, opportunities being given for the students to be present at the autopsies.

Professor Bartholow instituted last year an original plan in connection with his lectures for teaching therapeutics and materia medica. He has appointed an instructor in pharmacy (Dr. J. Mason McCollin), one in materia medica (Dr. N. K. Minich), and one in therapeutics (Dr. Frank Woodbury) to conduct a series of

demonstrations and examinations during the winter upon these branches, for which they are abundantly supplied with material and the proper apparatus of precision. Experimental therapeutics will also be carried on by advanced students interested in original studies of the action of drugs upon the lower animals. For these several departments no fee is charged beyond a small one for material furnished. This promises to be quite popular among the students.

The clinics at the new hospital and at the Pennsylvania Hospital are in the neighborhood.

At the close of the winter session a spring session is held, beginning early in April and ending early in June, embracing the following subjects:—

Clinical Surgery and Medicine, by the hospital staff; Clinical Lectures at the Pennsylvania Hospital, Professor Bartholow; Physiology and Comparative Anatomy, Professor W. C. Chapman; Electro-Therapeutics, ———; Diseases of the Urino-Genital Organs, Dr. S. W. Gross; Operative Surgery, Dr. J. H. Brinton; Ophthalmic Surgery, Professor William Thomson; Venereal and Cutaneous Diseases, ———; Laryngoscopy and Diseases of the Throat, Dr. J. Solis Cohen; Anatomy, Dr. William S. Forbes; Physical Diagnosis, Dr. J. Gibbons Hunt; Microscopy, Dr. J. C. Wilson; Pathological Anatomy, with demonstrations, Dr. Morris Longstreth; Diseases of Children, Dr. W. B. Atkinson; Toxicology, Dr. H. Lefmann; Urinary Pathology, Dr. Jos. S. Neff.

Attendance upon the summer course is allowed as office instruction, but does not count as a "session" of lectures.

There is no additional charge for the spring course of lectures to matriculates of the college, except a registration fee of five dollars. Non-matriculates pay the registration fee, and also \$35, *which latter sum is, however, credited on the amount of fees paid for the ensuing winter course.* And, while attendance on the fall or spring courses is not obligatory for graduation, the faculty earnestly recommend the student to avail himself of the advantages which are to be derived from these especial instructions.

The fees for the Jefferson College are matriculation five dollars, professors' tickets (\$20 each) \$140 (for the term \$280, no charge after the second term), graduation \$30. Total, \$315.

THE WOMEN'S MEDICAL COLLEGE.

This institution was chartered in 1850, since which time annual sessions have been held, and about three hundred ladies have been graduated in medicine. The college, situated in the northern part of the city, has a modern, commodious building, containing two large lecture rooms (seating three hundred each), and also large laboratories for chemical and pharmaceutical classes, dissecting, and for the museum. The sessions open in October and close at the end of February. A spring course is also held, which is free.

Early in the career of this college its authorities inaugurated the graded system of teaching, and established a chair of dental physiology and pathology, and a department of practical pharmacy, thus furnishing facilities for work in the pharmaceutical and chemical laboratories, which are kept open both during the winter and spring sessions. Lectures on histology and pathology are given weekly through the entire winter, with training in the use of the microscope. Among the features peculiar to the college may be specified the course in the pharmaceutical laboratory. Without additional fees regular weekly examinations are held through both winter and spring sessions. The college has an excellent though small library.

The Women's Hospital, in immediate proximity to the college, is a large, well-appointed building, admirably adapted for its purpose.

The faculty of the Women's Medical College, with the auxiliary instructors, is as follows:—

Mary J. Searlett-Dixon, M. D., Professor of Anatomy; Rachel L. Bodley, M. D., Professor of Chemistry and Toxicology; Benjamin B. Wilson, M. D., Professor of Surgery; Clara Marshall, M. D., Professor of Materia Medica and Therapeutics; Frances E. White, M. D., Professor of Physiology and Hygiene; Anna E. Broomall, M. D., Professor of Obstetrics and Gynecology; James B. Walker, M. D., Professor of Practice of Medicine; Alice Bennett, M. D., Demonstrator of Anatomy, etc.; J. Gibbons Hunt, M. D., Professor of Microscopy and Histology; C. Newlin Peirce, D. D. S., Professor of Dental Physiology and Pathology; W. W. Keen, M. D., Lecturer on Clinical Anatomy; Jos. B. Remington, Ph. G., Lecturer on Pharmacy; Edward T. Bruen, M. D., Lecturer on Pathology; Anna McAllister, M. D., Instructor in Obstetrics; Mary E. Allen, M. D., Demonstrator of Chemistry; Amy S. Barton, M. D., Instructor in Practice of Medicine; Emilie B. Dubois, M. D., Instructor in Materia Medica; Herrmann Haupt, Jr., M. D., Instructor in Physiology. Professor Rachel L. Bodley is Dean of the Faculty.

The whole cost of two or more courses of lectures and fee for graduation is \$265. Attendance upon two courses of lectures is required, the last to be at this college, and the candidate must have been engaged in the study of medicine for at least three years.

The advantages of Philadelphia as a medical centre need not be enlarged upon. The cleanliness and healthfulness of the city, the abundant supply of good water and good food at moderate prices, its convenience of location, and many attractions to the visitor can here only be mentioned. It can also be said with truth that its moral atmosphere (by no means an unimportant consideration "to parents and guardians") is rather better than some other large cities. As concerns its special inducements to medical students, which continue to attract them from all parts of the continent, we have very imperfectly indicated some of the more prominent of them. If the tree may be judged by its fruit, the profession can have no reason to complain of Philadelphia or her ancient halls of learning in regard to the quality of the instruction imparted by her distinguished teachers.

JOHNS HOPKINS UNIVERSITY.

COURSE ANTECEDENT TO THE STUDY OF MEDICINE.

THE Johns Hopkins University provides a special collegiate course for those who intend afterwards to study medicine. This course extends throughout three years, and, as a mental discipline, is equivalent to the other courses leading to the A. B. degree, which is therefore conferred on matriculated students who complete it. The main object held in view is to utilize for intending medical students the opportunities for practical study in physics, chemistry, and biology, found in an endowed institution with well-equipped laboratories, and so often wanting in medical schools; it is also considered an object to lessen the work to be subsequently crowded into the period of study at a medical school by giving the student a good knowledge of the sciences which lie at the basis of the medical art before he commences professional study. Physics, chemistry, and biology are therefore the main subjects included in the course; some knowledge of French and German is also demanded; and there

are, in addition, several subjects (inserted with a view to giving some breadth of culture) between which an option is allowed. These are Latin, Greek, mathematics, English literature, history, logic, and psychology. Each student must take up at least two of these optional subjects, the amount of knowledge required in each being such as would be obtained by a year's honest work.

The scientific subjects are taken up in the following order:—

I. PHYSICS.

There will be three recitations, two lectures, and one exercise in the physical laboratory weekly, through a year, at ten A. M.

Elementary mechanics will be studied during the first portion of the year; then will follow, in the order named, the study of the physical properties of matter, theories of undulations, acoustics, heat, magnetism, electricity, and light.

The lectures have as their aim the elucidation, by means of experimental demonstrations, of the subjects pursued by the class.

A morning of each week will be assigned for the work in the laboratory. This work will be selected with two principal ends in view: first, to give the student a clearer insight into the subjects studied, serving as a test of progress both to teacher and learner; and, second, to enable him to acquire a familiarity with the use of apparatus. The manner of conducting the exercise will be as follows: With the enunciation of a problem, each student will receive the apparatus necessary for its solution, and will be required to make the series of observations which, with their discussion and reduction, he is to submit to his instructor. These results will then be criticised and returned. Those who are aiming at the profession of medicine will thus grow familiar with physical instruments and methods which are of prime importance in physiological researches, for example, thermometry, the laws governing the phenomena of electricity, of light, etc. A knowledge of trigonometry is in all cases requisite before entering on this course.

II. CHEMISTRY.

The course of lectures and recitations on general chemistry is in progress through the year, at nine A. M. Students of this course are expected to attend all these exercises during the first year, and during the last half of the first year and the first half of the second year to work daily in the chemical laboratory. The instruction in the laboratory will be directed in such a way as seems best adapted to give the student a thorough knowledge of the pure science of chemistry and the methods peculiar to it. This kind of instruction is considered to be the best basis, whatever the object may be which the student has in view.

At first the student will have to make himself acquainted with the action of the various classes of substances upon each other by actual observation at the laboratory desk; and his knowledge will be constantly tested by means of appropriate problems given him for solution. After completing this course, he will be enabled farther to test his acquirements by taking up a course of qualitative and quantitative analysis. At intervals during the time he is engaged in this work, he will be required to prepare some chemical compounds in a pure state, so that his ideas concerning chemical action may become enlarged, and his knowledge of the special properties of the different classes of compounds more definite and detailed.

Opportunity is given in the laboratory for the prosecution of the study of chemistry to any extent, but generally the course thus briefly sketched will suffice for one who looks toward a course in medicine.

III. BIOLOGY.

The study of biology will begin in the second year, that is to say, after the student has made considerable progress in the study of physics and chemistry, and will continue through the third year. Those who have acquired elsewhere sufficient knowledge of the above subjects to satisfy the examiners may be at once admitted to work in the biological laboratory.

The course is designed to give the student, in the first place, a knowledge of the laws of life in general, whether exhibited in animals or plants; and, secondly, a knowledge of human anatomy and physiology. Human physiology is taught as a part of general physiological science, the student being left to acquire afterwards its clinical and hygienic applications as part of his medical studies proper; and similarly surgical and regional anatomy are left for the medical school proper; the student in

this course studies the human body as the final one in a series of animal types.

It is believed that by approaching these sciences from a general scientific stand-point the student is best prepared for the study of pathological structure and function; and that a great advantage will result from his being able to concentrate his attention on the professional applications of these studies when he enters a medical school.

The order of study is as follows:—

(1.) *General Biology.*—Lectures, recitations, or examinations four times weekly throughout one year, with daily laboratory instruction. This course is intended to bring prominently before the student the fundamental facts of biology as gathered from a detailed study of a number of typical plants and an animal from each class of the animal kingdom. The embryology of the chick is also studied in detail.

In this course beginners are taught how to use the microscope and to dissect.

(2.) *Human and Comparative Osteology.*—About sixty lectures or recitations.

These biological courses, with the corresponding laboratory study, give the student from three to four hours' work daily throughout the year.

The closing year of the preliminary medical course includes:

(3.) *Human Anatomy.*—This course extends from the commencement of the academic year to the end of March, and consists chiefly of demonstrations and practical study in the dissecting-room.

(4.) *Animal Physiology and Histology.*—Mainly with reference to the human body. Three lectures or examinations weekly throughout the academic year. The microscopic structure of the tissues and organs is studied in this course, except so much as may have already been gone through in the general biology course. Students are required to perform for themselves the simpler physiological experiments, while other more difficult but important facts are demonstrated to them.

The physiological apparatus belonging to the university is unusually good and complete, and students who follow this course will require a knowledge of the method of using all the chief instruments employed in physiological research; and, so it is hoped, will be able afterwards to carry out scientific investigations on the physiological action of drugs, in experimental pathology, etc.

(5.) From time to time short advanced courses of lectures on special physiological topics are delivered.

IV. SUMMARY OF THE COURSE.

Requisite for Matriculation: A good English education; Latin; Greek, or French and German; mathematics; physical geography.¹

First Year.—Physics (daily); chemistry (daily); German; English physiology.

Second Year.—Chemistry (daily, first half year); general biology (daily); French; English drawing.

Third Year.—Physiology and anatomy (daily); logic; psychology.

At the option of the student during the three years, mathematics; ancient languages; and various courses of lectures.

V. ADDITIONAL INFORMATION.

(1.) Students not unfrequently having presented themselves for admission to the preliminary medical course without the knowledge required to pass the full matriculation examination, and yet apparently fitted to profit by the course, the university authorities receive such if they possess an elementary knowledge of Latin (sufficient, for example, to translate *Cæsar* and *Virgil*, with a knowledge of accidence), and also of arithmetic, algebra, and geometry. Such candidates must in their answers conform to the rules of English grammar, including orthography, and no candidate will be approved who fails to satisfy the examiners in this respect. The student may, however (and is always encouraged and advised to), offer himself for matriculation at any time during his course, and may, after passing his matriculation examination, present himself in the regular course for a degree.

(2.) For requirements and opportunities in the study of mathematics, ancient and modern languages, history, psychology, etc., reference may be made to announcements in the University Register and Programme. It is only necessary to mention here that in French and German students will receive such

¹ If the candidate enter with a knowledge of French and German other studies may be substituted for them during the progress of the course.

instruction as should enable them to read at sight French and German, and to render English into French and German, and to understand French and German grammar; and that courses in English philology and literature will be in progress during the year.

(3.) Instruction is provided by the university in comparative anatomy and botany, but attendance upon special courses in these subjects is not required of all who follow the preliminary medical course, as the general principles and more important facts are taught in the course of general biology.

(4.) College graduates from approved institutions, having already obtained a liberal education, are permitted to concentrate their attention on the scientific courses, and so may complete the curriculum of the above course preliminary to medical studies in less than the usual three years. On the other hand, a student may, if he wish, spend a longer time in these preparatory studies, or take up additional ones.

(5.) It may be added that the trustees and instructors of the university are especially anxious to promote post-graduate study and original research. Medical men or others properly fitted to profit by such opportunities are received for advanced study or investigation in chemistry, histology, or physiology, as well as other subjects. The equipments of the university for such purposes are unusually complete. Twenty fellowships, each bringing in five hundred dollars per annum, are annually awarded to advanced students, at least three being in chemistry and an equal number in biology.

The buildings of the Johns Hopkins Hospital are now in course of erection. When completed a medical school will be instituted in connection with the hospital. This it is hoped to make adapted for post-graduate study, and for training in the more scientific branches of medicine, as hygiene, pathological chemistry, experimental pathology, experimental therapeutics, etc., so that the student who has already acquired a thorough practical knowledge of chemistry and physiology and normal anatomy can carry on advanced study or research in connection with disease.

As yet, however, no steps have been taken in connection with the organization of the medical school proper, and no authoritative statements can be made.

THE HARVARD MEDICAL SCHOOL.

THOSE interested in the progress of medical education in this country are already sufficiently familiar with the general features of the changes which have taken place at the Harvard Medical School within the past ten years. They are also aware that the results have in every way proven gratifying to the friends of the college, and stimulating to the medical profession in other States, and to medical schools in various sections of the country. It is well known that the effect of these changes has been to improve the quality of the students, to increase the income of the school, and to add largely to the number of instructors. These results have been mainly attained by offering such inducements as have resulted in a prolongation of the period of residence of each student at the school. In 1872 only five per cent. of the graduates had remained three years at the school, while in 1879 eighty-eight per cent. of the graduates had remained at the school during their three years of study. It must be evident to every unprejudiced observer that measures which will lead to such a prolongation of the period of study deserve every encouragement, if such measures are considered to represent additional requirements and additional opportunities. That the latter are far greater and more numerous in 1881 than in 1870 is so obvious to every person at all familiar with the history of this school during the past decade that it would seem superfluous to direct attention to the printed annual reports of the president of Harvard College.

The latest changes which have taken place at the Harvard Medical School are such as carry out the spirit of all earlier advances, and tend to make still wider the interval which may lie between this school and those which strive to compete with it in promoting the cause of medical education in this country. These changes consist in additional requirements for admission, and an extension of the period of study.

When they first demanded an examination for admission, the faculty felt that so obsolete a custom must not be restored in such an abrupt manner as to turn away many candidates who were sure to make excellent physicians, although they might not have had the fullest opportunities of college training. The examination was, therefore, made sufficiently stringent to insure a certain liberality of education, still more a certain training which should enable the student to appreciate the opportunities of study afforded by the medical school. The study of a language other than English, and the study of physics, were thought to indicate a knowledge of many other subjects, and an examination in Latin, French, or German, and physics, was offered as a test of the sort of preliminary education the applicant had been able to obtain. The standard in Latin was purposely made high to exclude the school-boy who might have studied this language for two or more years, and yet have had but little opportunity to progress in the study of mathematics, natural science, or general literature. The effect of this admission-examination was immediate, improving the quality of the students. Before it was instituted the inefficient or incompetent students failed to advance with their class, and gradually withdrew from the school, either to give up the study of medicine altogether, or to seek for a degree elsewhere. Candidates who are unlikely to profit by the opportunities offered are now prevented from entering the school, at all events until they have fitted themselves to profit by their surroundings.

It has been thought by the faculty that this test should be made still more delicate. They have determined, therefore, to exact a knowledge of Latin, instead of accepting another language as an equivalent, to require, as heretofore, an examination in physics, to demand a special examination in English, likewise an examination in either French, German, the elements of algebra or of plane geometry, or botany. This examination applies to all candidates for admission, with the exception of those holding a literary or scientific degree, and those who have already passed the more stringent examination for admission to the college, and must be passed before the students are admitted to the school.

An extension of the period of study to four years is the other step which the faculty have seen fit to establish. It has been apparent for some years past that the amount of instruction given in the third year was greater than could be properly assimilated. The students were not slow in learning this fact, and either failed to attend certain exercises in subjects in which there was no searching examination, or voluntarily attended the exercises of the school during a fourth year. The latter class were thus enabled to lighten the work of the third year, and at the same time to avail themselves of all the instruction given. To persuade more students to remain four years is the present effort of the faculty.

As the three years' course is to be as full and com-

plete as heretofore, and students are permitted to graduate at the close of this three years' course, it was necessary to make the additional year of study voluntary. It has therefore been the design of the faculty to make the fourth year so attractive that students would feel a keen sense of the advantages to be gained by adding to their period of study. Every effort has been made to give special clinical opportunities to students of the fourth year in all the specialties, as well as in medicine and surgery; to furnish practical instruction in such subjects as mental disease, forensic medicine, and hygiene; to add to the efficiency and thoroughness of operative courses in surgery, obstetrics, and gynecology; and to open the laboratories of physiology, chemistry, and pathological anatomy in the fullest and freest manner, for such advanced students to investigate those subjects which may be of special interest to them. The essential features of this fourth year are the opportunities of instruction offered to the individual. He becomes one of a class of three or four, instead of one in a class of fifty or a hundred.

As attendance upon this fourth year is voluntary, so an examination in its work is not insisted upon. The attempt is made, however, to encourage the students to be examined by offering a special degree, which shall indicate not only that they have studied four years, but that they have attained an average of seventy-five per cent. in all the examinations of these years. For those who may desire the opportunities offered, yet either fail to reach the standard or be unwilling to try for it, a certificate of attendance in the studies of the fourth year, in addition to the ordinary degree of doctor of medicine, will be given.

Such are the latest efforts made by this school to educate better physicians for the country at large, and to bring medical education in the United States more nearly to the level maintained by the great schools of Europe. May the time soon come when the voluntary fourth year shall be made compulsory, and all our medical schools be enabled to offer the best opportunities at the least cost.

THE MEDICAL SCHOOL OF MAINE.

THIS venerable institution, the medical department of Bowdoin College, enters upon its sixty-second annual course of instruction on the ninth of February next. It was established in 1820, at a time when the vast majority of the medical practitioners of the State of Maine had received no systematic education, but had picked up their knowledge of physic under the supervision of their private preceptors, — a method not entirely devoid of advantages which are not presented by our modern system, but not well calculated to develop the intellectual capacities, or to impart a broad and deep knowledge of the science and art of medicine. The new school, being well officered and receiving the countenance and financial aid of the legislature, was not slow in making its influence felt; and before many years had passed it was quite as generally the rule, as it had formerly been the exception, for practitioners to have diplomas which certified their graduation from a respectable institution.

This school, while not attempting to compete with metropolitan institutions, has always done and is still doing a most important service to the profession and the community. It affords, at a moderate price, an

excellent medical education to a considerable number of young men, who are determined to practice medicine, but are unable to attend the more extended and expensive courses of instruction in the large cities. They supply places which, without them, would have to depend for medical advice upon ignorant and unprincipled charlatans. The standard of the school is being elevated as rapidly as the integrity of the institution will warrant, and is already creditably high, as will be seen by the following statement of requirements and advantages.

Before a student can become a member of the class, he must give satisfactory evidence of possessing a fair English education. All who cannot show diplomas from recognized academies and high schools must pass a written examination in the ordinary branches. Being admitted, the student finds that, while the plan of lectures which is usual in colleges obtains here, the course is practically graded for those who prefer this better method. The faculty advises him to devote his time in the first year to the elementary branches, in the second to those which naturally follow, and in the third to the most difficult topics, the study of which necessitates a knowledge of the previous departments. At the end of the first year the final examinations in anatomy, physiology, and chemistry are held; at the end of the second those in materia medica and obstetrics; and at the close of the third those in practice, surgery, and gynecology. The pursuit of this method is optional, but a large number adopt it, and it is growing in favor. If a student chooses, he may take all his examinations at the end of his third year of study.

The members of the faculty hold frequent quizzes without extra compensation, a service which is greatly appreciated by the students, who value these exercises as highly as the lectures.

The examinations are both written and oral, and are of a searching character. Applicants must have dissected three parts of the body, have written a thesis, and have studied medicine three years.

Though situated in a country town, the school affords good opportunities for witnessing surgical and medical cases. The clinics are very large, the patients coming from all, even distant, parts of the State to receive free treatment. The means for studying practical chemistry and anatomy are superior. The faculty is composed of men who have had long experience in teaching, and who, appreciating the responsibility of their positions, are anxious to do all in their power to advance the interests of the medical profession.

PORTLAND SCHOOL FOR MEDICAL INSTRUCTION.

This is not a diploma-conferring institution, but simply, as its name implies, a school in which medicine is taught. It takes the place of private preceptorship, the difference being that, while with a preceptor a student is generally left to follow such plan of reading or idleness as his discretion or folly may dictate, and gets no help from his nominal teacher from beginning to end of the year, in this school he has systematic daily instruction in all the fundamental branches and a number of the specialties, and is held to a strict accountability in the performance of his duties by a corps of eleven competent physicians, each of whom devotes especial attention to the work of his own department. Recitations, lectures, clinics, demonstrations, dissections, all receive their share of attention. The school is admirably equipped with apparatus and material of vari-

ous kinds. The Maine General Hospital, the Greely Hospital, and the Portland Dispensary afford ample clinical advantages.

The educational standing of the school is higher than that of most medical colleges, applicants being required to pass a written examination in English, and in elementary Latin and physics.

This school fully supplements the work of the Medical School of Maine, its sessions occupying eight months of the year, and those of the latter institution the remaining four. The entire year is thus consumed. The success which those who have taken their medical education in these schools attain in the practice of their profession is the best evidence of the quality of the instruction given.

THE CHICAGO MEDICAL SCHOOLS.

The regular medical schools of Chicago are the Rush, Chicago, and Women's Hospital Medical colleges.

The Rush was organized nearly forty years ago, and was the only medical institution here for many years. Twenty-two years ago the

CHICAGO MEDICAL COLLEGE

was organized mostly by gentlemen who resigned from positions in Rush College to enter its faculty. The Chicago College was founded for the purpose of inaugurating and carrying out a change in the method of teaching which was thought to be an improvement on the practice then in vogue in this country. That practice was for students to attend two courses of lectures, of about four months each, before graduating, the lectures of the successive courses being practically identical. The plan of the Chicago was to divide the studies into the elementary or junior branches and the practical or senior branches, and recommend that students attend these courses respectively during successive terms. At the end of the junior course a student was allowed to pass his final examination on the branches of the course, and have thereafter nothing but the senior branches to attend to.

History will accord this school the credit of having first adopted the "graded system" in these years in this country.

The plan is certainly philosophical, as it has proved to be in literary colleges, and much was hoped for it in the advancement of the profession. But as it exacted nothing that other colleges did not require, but only rearranged and put in different sequence what all the first-class schools were teaching, it did not constitute an elevation of the standard in the true sense. No higher grade of requirements was made, no better qualifications for a degree were exacted; the studies were only made more convenient for the student. The result was that no better doctors were turned out; the fountain was not made higher; at the same time a student found it easier to pass his examination by this plan than under the old system.

It was not till a very few years ago that the standard was really raised by this excellent school, when it required an entrance examination in English, and lengthened its course. Its course is now six months long, and the studies are divided into three groups, junior, middle, and senior, and students are advised to take these respectively in successive years, and to pass final examinations in the studies taken at the end of

the respective years. Two courses of lectures, however, are all that is exacted, and such as do not attend more divide the "middle" branches between the junior and senior courses.

The entrance examination for applicants not presenting diplomas of academic institutions has doubtless done good in improving the character of the classes, but the examination is unfortunate in being wholly arbitrary and subject to the personal notion of the examiner. It may be severe or utterly useless, according to the individual bias. "Applicants must possess at least a good English education," and failing to present documentary proof they "must sustain a satisfactory examination before a committee of the faculty." When a rule of this sort is so wanting in specific definition of its meaning, great confidence in its uniform and beneficial working should not be expected. The term "satisfactory" is too flexible when applied to such an examination. For a strictly medical examination usage has defined the word well enough. This school has a good chemical laboratory, where students who desire may pursue practical chemistry. Quite a proportion of the classes do so.

The clinical facilities that are used are the Mercy Hospital in an adjoining building, and the dispensary in the college building. The hospital usually has about fifty patients, and the clinical advantages both there and at the dispensary are worked up to an admirable degree of perfection. The hospital medical staff are all members of the college faculty. The dispensary is largely attended, several thousand patients visiting it annually, and students regularly rotate in their attendance upon the several departments, so there is no crowding, and the best use is made of the material.

The lying-in department of the hospital is sufficiently extensive generally to enable each member of the graduating class to witness one case of obstetrics at least. Students are allowed to attend the County Hospital, but this is so far off (five and three quarters miles) that they do not visit it.

One course of dissections is made obligatory. Students must pursue the clinics of Mercy Hospital at least one term. A thesis is required. Students who desire may have instruction in practical physiology.

A practitioners' course of four weeks was inaugurated last spring immediately after the Commencement, and was very successful, thirty-nine gentlemen being in attendance. The fee for this course is \$30. This school united with Rush two years ago in raising the fees from about \$50 to \$75. The graduation, or final examination fee is \$30.

RUSH COLLEGE,

as already stated, is about forty years old. Twenty years ago the regular course of lectures had a duration of sixteen weeks. Within a few years it has been lengthened several times, so that it now continues twenty-one weeks. In addition there is a spring term of sixteen weeks that is a complete course of lectures in itself; this is practically free to the regular students of the institution, but does not count as a "course of lectures" in the conditions of graduation.

The two regular courses of lectures required for the degree are practically identical; there is no grading of the course, but students are advised to devote themselves mainly to the elementary studies during the first year, and this advice is emphasized to such as take three or more courses of lectures.

The rule of one and only one final examination has never been modified till a year ago, when it was decreed that students who will attend at least three winter courses may pass their final examination in anatomy, physiology, materia medica, and chemistry at the end of the second winter course.

The clinical facilities are the college clinics, seven each week, the Central Free Dispensary (in the same building), at which a hundred or more patients attend each day, and the Cook County Hospital.

The college clinics, occurring each week, that are public to all the class, are one each on surgery, orthopaedic surgery, gynaecology, dermatology, and venereal diseases, nervous diseases, diseases of the chest, and general medicine. In addition there is a daily clinic in gynaecology, attended by an average of eight patients each, to which small sections of the graduating class only are admitted.

There are several public clinics in the Central Dispensary each week, and in the prescribing rooms small sections of the graduating class are received in rotation by a system of cards of admission.

The County Hospital is under control of the county commissioners. Of its medical staff three members belong to the faculty of the Chicago College, three are from Rush College, and seven belong to no college.

The hospital stands opposite the college, is the public (charity) hospital, and the largest in the city, having three hundred beds. Students are required before graduation to have attended at least one year the clinics and post-mortem examinations at the hospital. There is a spacious amphitheatre for clinics and another for post-mortem exhibitions, with all the modern appliances. There are six public clinics in the hospital each week.

The college has a students' chemical laboratory, capable of accommodating about thirty at work at one time. A course in practical chemistry is obligatory, and the briefest course allowed is one consisting of thorough urinalysis, a short course in general toxicology, and a similar one in general qualitative analysis. There is a course on practical physiology, but it is optional. Practical anatomy is required, "and to the extent of having dissected each region of the body."

The fees are seventy-five dollars, exclusive of matriculation (five dollars), laboratory and dissecting tickets, (each five dollars), and the examination fee is thirty dollars, but the fee is not returnable in case the candidate fails. No thesis is required, but most of the examinations are in writing.

The announcement has been made by this school that after March 1, 1883, all new applicants will be required to submit to an examination, unless they have passed an entrance examination in some respectable literary college or are graduates of a high school. The examination is to include only the elements of physical sciences as taught in common school textbooks and arithmetic to cube root, but the examinations are to be in writing, and the papers are to be judged critically as to "spelling, knowledge of grammar, and composition exhibited."

The spring course is conducted mainly by a faculty of lecturers, who do not teach regularly in the winter course. To encourage a higher grade of attainments a special certificate of honor is awarded to students who attend three winter and at least one spring term. A post-graduate course was established lately. At first it occurred during the latter part of the regular

winter session, when the college was full of students, which was found to be inconvenient. Hereafter it is to follow the regular course, and continue four weeks. The fee for this course is thirty dollars.

The number attending the practitioners' course last winter was seventy-seven, the whole number of students attending the last winter course was five hundred and fifty-nine. The graduates of 1881 were one hundred and seventy-two.

THE WOMEN'S COLLEGE

is eleven years old, and is in every way a first-class school. It receives women only; divides the curriculum into junior and senior studies, and advises that they be taken in successive years; has an entrance examination for those not bringing "certificates of graduation from a high school or like institution, or a teacher's certificate from a county superintendent of schools," but the line up to which students must come in such examination is not stated.

The requirements for graduation are rigid. In addition to the three years' study and two lecture terms the student must have "dissected each of the usual divisions of the body at least once," and have attended one course of clinical instruction; she must also take a course in practical chemistry in the laboratory; she must write a thesis. While the studies are divided into junior and senior branches, the student is not allowed an examination at the end of the first course. The final examination covers all branches taught.

The clinical advantages are several college clinics, the Cook County Hospital, which is directly opposite, the Hospital for Women and Children, four blocks away, and Central Free Dispensary, one and one half blocks away.

The Hospital for Women and Children is wholly under the professional care of female physicians; it has about thirty beds and is always full.

The college has a very excellent summer course of lectures, given mostly by members of the faculty.

Each of the three colleges has a permanent building of its own, built after the modern notion of things, and very well adapted to its wants. Perhaps the most perfect one is that of the Women's College. The best and most spacious lecture-room is the upper amphitheatre at Rush, — which has a seating capacity of five hundred, — unless it be the clinical amphitheatre of the County Hospital, which is even larger.

THE DETROIT MEDICAL COLLEGE.

The course of instruction at this college is introduced by a definite written examination in English composition, in arithmetic, in algebra, and in physics.

The obligatory attendance upon college drill covers three yearly terms of six months each. The college requires daily laboratory work during the first two years, and daily clinical work during the last year. It requires attendance upon from three to four lectures or recitations daily during the three terms. During the first two terms it requires attendance upon one or two clinical lectures each day. During the last year, each student is obliged to spend from one to three hours daily in actual clinical work in hospital wards or in dispensaries. It requires that each student shall pass satisfactory examinations at the end of each term upon the studies he has actually pursued, and upon the laboratory or clinical work he has actually performed.

The plan of study is carefully graded. All instruction is so arranged that each branch may aid in the comprehension of each other branch pursued at the same time, and that these together shall prepare the way for the most easy and perfect comprehension of those which follow. The instruction of each class is prepared for and given to it alone, and always in a room separate from the other classes. Thus the separation of the three classes is as distinct as in the best literary colleges. The freshman class must, during each week, attend four lectures or recitations on anatomy, four on physiology, three on chemistry, three upon materia medica, and one on pharmacy. It must work twelve hours weekly for four months in the chemical laboratory, and for two months in the laboratory of practical pharmacy.

The junior class must attend each week four lectures or recitations upon anatomy, four upon physiology, two upon medical chemistry, three upon therapeutics, and four upon morbid anatomy and pathology. It must work twelve hours per week in the dissecting-room for three months, and in the physiological and histological laboratory for three months. The senior class must attend four lectures a week upon general surgery, five lectures or recitations per week upon practice of medicine, two upon diseases of women, three upon obstetrics, one upon diseases of the eye and ear, one upon diseases of the larynx or genito-urinary apparatus, one upon diseases of children, one upon nervous diseases, and one upon toxicology and medical jurisprudence. It must also work in small sections (each section being in charge of a clinical teacher) from one to three hours daily in hospital wards or dispensaries. Three hospitals, with from thirty to one hundred beds each, and two large dispensaries, situated in a city of one hundred and thirty-five thousand people, afford ample clinical material. The four laboratories are large, well lighted and fitted with all modern conveniences for the successful study of the four fundamental branches of medicine and surgery.

CHARLESTON.

THE MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA enters upon its sixtieth anniversary session. In sympathetic and coöperative affiliation with such institutions as are moving through the only avenue that can conduct their labors to a broader, more complete, and more productive field of usefulness, this college has seen fit to indorse and accept the three years' term of a graded course of instruction as the necessary requirement for graduation. The difficulties inherent to an internecine war have fortunately been surmounted, and the successes of the past few years encourage the hope that the present step, which otherwise would long since have been taken, will add to the reputation the college has always enjoyed.

Larger classes of students and greater proficiency among the graduates of late bear attestation to the continued popularity of this school, and to a more earnest aim among its attendants at the acquirement of that knowledge in search of which they are engaged. A more protracted course of studies, a higher standard of requirements, and necessarily a more complete final examination may and doubtless will in the future drive some away, but the faculty have not allowed expediency to interfere with duty, and they feel assured that

they will at least secure that better class of aspirants for medical renown who in time must reflect greater credit upon their alma mater.

The Medical College adjoins the Roper Hospital, which is a great advantage, since attendance upon the clinical lectures in the one and the didactic prelections in the other necessitates no loss of time in transit from one building to the other.

The present *régime* has wrought important changes in the management of the Roper Hospital.

The faculty, long since recognizing the importance of a regular, systematic annual course of clinical teachings to students, attracted to colleges only which were able to offer such facilities, saw fit to urge these claims and requisitions of a high medical educational curriculum upon the intelligent consideration of the council; while they proposed that their own professional services would be offered *gratuitously* to the city, giving every pledge on their part for the conscientious and punctual discharge of their self-imposed duties to the sick poor. Though some opposition arose in council upon the subject, as was to be expected, yet, as *nos besoins sont nos forces*, this appeal was not made in vain. The Roper Hospital has at length been turned over to the faculty of the Medical College, who have entire control now of all that concerns the medical and surgical treatment of the sick. Private cases in the practice of the professors are, whenever they see fit, brought to the hospital; and patients coming to the city addressed to either of these gentlemen are accommodated in private apartments, the appointments of which are in every respect suitable to pay patients, at a reasonable *per diem*.

Clinical instruction in various branches is given during the winter session to large classes; and all the year round clinical prelections are offered to those students remaining with us. These didactic lessons are perhaps the more useful because the more varied, since they are apportioned among six professors, a medical and a surgical clinician for each term of four months. Four house physicians or *internes*, make up the complement of a full corps of professional attendants in constant and efficient ministrations upon the sick.

Not very anxious to encumber themselves with the financial concerns of the hospital, the medical faculty requested at once to be exonerated from such an additional tax upon their time and labors, and we are pleased to announce that a board of commissioners were appointed. This division of labor between the purely medical and administrative concerns of a hospital, in its operations entirely independent of each other, is a most provident arrangement, was a consummation greatly to be wished for, particularly in view of the recent difficulties at Guy's Hospital and other organizations nearer home, and has worked admirably so far. With a laudable desire to exhibit their efficiency and interest in the welfare of the hospital, the commissioners have already improved the buildings in many respects, particularly in fitting up and embellishing the private apartments of pay patients, while further changes are in contemplation which will make the Roper Hospital one of the most complete and acceptable charities of its kind in the Southern States.

THE MEDICAL SCHOOLS AT LOUISVILLE.

UNIVERSITY OF LOUISVILLE. — The forty-sixth regular term begins October 3d, and lasts five months.

LOUISVILLE MEDICAL COLLEGE. — The thirteenth regular session begins October 3d, and lasts five months.

HOSPITAL MEDICAL COLLEGE. — The eighth regular session begins October 3d, and lasts five months.

KENTUCKY SCHOOL OF MEDICINE. — The next regular session, which is the fourth since the reorganization of the school apart from the Louisville Medical College will be held from March to June (inclusive).

There are four schools of medicine in Louisville, as above enumerated, — three holding their session in winter and one in spring. Since the disruption of the Kentucky School of Medicine from the Louisville Medical College, three years since, the several schools pursue independent courses.

The plan of instruction in all is essentially the same, — by lecture and quiz. Recitation terms (optional) are held during the spring by the winter schools. Provision is made for graded course for such as desire it. There are daily clinics at the University and Hospital schools, and semi-weekly classes at the City Hospital, in which all the schools participate. The University supplies special demonstrators for microscopy, histology, chemistry, dressings, etc.

The Louisville schools are all members of the American College Association. The requirements for graduation are three years' study and two courses of lectures. They stand pledged to require three courses after 1882.

By mutual agreement of the winter schools, the lecture ticket will hereafter not be issued to matriculates until February. This is done to insure, somewhat, attendance at lectures.

The Medical Service of the United States.

THE UNITED STATES ARMY.

The following memorandum is prepared for the information of persons desirous of entering the medical corps of the United States Army: —

[EXTRACT FROM LAWS OF THE UNITED STATES.]

Act of Congress, Approved June 30, 1834.

Section 1. *Be it enacted, etc.* That from and after the passage of this act no person shall receive the appointment of assistant surgeon in the Army of the United States, unless he shall have been examined and approved by an Army Medical Board, to consist of not less than three surgeons or assistant surgeons, who shall be designated for that purpose by the secretary of war; and no person shall receive the appointment of surgeon in the Army of the United States unless he shall have served at least five years as an assistant surgeon, and unless, also, he shall have been examined by an Army Medical Board constituted as aforesaid.

Act of Congress, Approved June 23, 1874, and June 26, 1876.

Sec. IV. That the medical department of the army shall hereafter consist of one surgeon-general, . . . one assistant surgeon-general, . . . one chief medical purveyor, four surgeons, with the rank, pay, and emoluments of colonels, two assistant medical purveyors, . . . eight surgeons, with the rank, pay, and emoluments of lieutenant-colonels, fifty surgeons, with the rank, pay, and emoluments of majors, one hundred and twenty-five assistant surgeons, with the rank, pay, and emoluments of lieutenants of cavalry for the first five years' service, and with the rank, pay, and emoluments of captains of cavalry after five years' service, . . .

All candidates for appointment in the medical corps must apply to the honorable secretary of war for an invitation to appear before the Medical Examining Board. The application must be in the handwriting of the candidate, stating age and birthplace, and he accom-

panied by testimonials from professors of the college in which he graduated, or from other physicians in good repute. Candidates must be between twenty-one and twenty-eight years of age (without any exceptions), and graduates of a regular medical college, evidence of which must be submitted to the board before examination.

The morals, habits, physical and mental qualifications, and general aptitude for the service of each candidate will be subjects for careful examination by the Board, and a favorable report will not be made in any case in which there is a reasonable doubt.

The following will be the general plan of the examination:—

I. A short essay, either autobiographical or upon some professional subject to be indicated by the board.

II. Physical examination. This will be rigid, and each candidate will, in addition, be required to certify, "*that he labors under no mental or physical infirmity, nor disability of any kind, which can in any way interfere with the most efficient discharge of his duties in any climate.*"

III. Oral examinations on subjects of preliminary education, general literature and general science. The candidate must satisfy the board in this examination that he possesses a *thorough knowledge of the branches taught in the common schools, and a failure to show this will end his examination.*

Oral examination on scientific subjects will include chemistry and natural philosophy; and that on literary subjects will include English literature, history of the United States, and general history, — ancient and modern. Candidates professing a knowledge of the higher mathematics, the ancient and modern languages, will be examined therein, and due credit given for a proficiency in any or all of these subjects.

IV. Written examination on anatomy, physiology, surgery, practice of medicine and general pathology, obstetrics, and diseases of women and children. Oral examination on these subjects, and also on medical jurisprudence, materia medica, therapeutics, pharmacy, toxicology, and hygiene. Few candidates pay the attention to hygiene which it deserves; it is made an important subject in this examination.

V. Clinical examination, medical and surgical, at a hospital.

VI. Performance of surgical operations on the cadaver.

The board will deviate from this general plan whenever necessary, in such manner as they deem best to secure the interests of the service.

The board will report the merits of the candidates on the several branches of the examination, and their relative merit in the whole, according to which the approved candidates will receive appointments to existing vacancies, or to vacancies which may occur within two years thereafter.

An applicant failing one examination may be allowed a second after one year, but not a third.

No allowance will be made for the expenses of persons undergoing examination, as this is an indispensable prerequisite to appointment, but those who are approved and receive appointments will be entitled to transportation on obeying their first order.

THE UNITED STATES NAVY.

THE RELATIONS OF THE MEDICAL CORPS OF THE NAVY TO MEDICAL EDUCATION.

ADMISSION into the medical corps of the United States Navy can only be obtained through a professional examination before the Naval Medical Board, composed of medical officers of the higher grades. From the very beginning this board has assumed to

be the sole judge of the qualifications of candidates, the mere possession of the diploma of a medical school having no weight whatever as an evidence of professional capacity; and the experience of the board has demonstrated that the most incompetent applicants have been found among graduates of the great schools, while many of the ablest men of the corps have received their degrees from comparatively obscure institutions.

The candidate is presumed to have received a proper liberal education. A biographical sketch, an essay on some assigned subject, and written answers to a series of comprehensive questions in the various branches of medicine are intended as evidences of such proficiency, the orthography, grammatical construction, form, and manner of expression being as carefully scrutinized as accuracy of statement. An oral examination follows by the several members of the board in every branch of medicine, and upon such collateral studies as the candidate may have pursued, with the object not merely of ascertaining the amount of detailed information he may have learned by rote, but rather his intelligent comprehension of the fundamental facts and principles which constitute the science of medicine. Finally, extemporaneous chemical and pharmaceutic manipulations, the clinical diagnosis and treatment of actual patients in hospital, the adjustment of surgical appliances and apparatus, and the performance of operations upon the cadaver exhibit his cognizance of the practical requirements of the healing art, and his ability to assume its responsibilities, under the emergencies of a career which sometimes places the issue of life or death upon his unaided knowledge and skill.

A second examination is required for passing out of the grade of assistant surgeon, preliminary to promotion to that of surgeon, and took place, formerly, five years subsequent to the first. Recently the interval has been injudiciously lessened to the completion of two years' service on board a man-of-war. This examination presupposes a wider practical acquaintance with the various branches of medicine, particularly in the special departments which have arisen, and a familiarity with the current literature of the profession, facilities for which are now liberally provided by the Bureau of Medicine and Surgery, under the administration of its present chief, Dr. Wales. It has been the custom to allow a period of preparation for this final examination, but as its object is to ascertain the fitness of the individual for occasions when his knowledge as a medical or sanitary officer may be of need, it is manifest that such a preliminary cramming, evidencing a greater or less ability to memorize facts, is inconsistent with its real purpose, while it operates unequally upon the members of a date, under the diverse circumstances of their duty ashore and afloat. An impromptu examination, while it might not exhibit such finished results, would furnish a more accurate measure of the real acquirements of the class examined.

The bureau's interest in the officer does not cease with his final examination. Individual research and investigation are encouraged by the supply of apparatus, instruments, or opportunities required, and by the publication of essays voluntarily contributed, as well as by the requirements of annual medical and sanitary reports from every officer in charge of the medical department of a vessel or station, embracing the medical topography, climatology and hygiene of every

station or place visited, with all attainable information respecting statistics of disease and its causes, establishments for the care of the sick, charitable institutions, medical colleges, or other matters of professional interest.

A medical education, such as admission into the medical corps of the navy implies, has until quite lately scarcely been attainable through the ordinary curriculum of any school in this country, and those who have passed the examination have been men whose industry, ambition, and thirst for knowledge, under the guidance of competent preceptors, have impelled them to seek for themselves that fuller professional training of which they have felt the need. Happily, a number of the leading schools, disregarding possible pecuniary loss from smaller classes, have begun a reform in medical teaching, which promises to make their graduates as really "learned in medicine" as the phraseology of their diplomas implies, and ultimately we may hope that every reputable college will be compelled to the same thoroughness of teaching. This accomplished, the most sublime and profound and ennobling of the sciences will be delivered from the hands of empirics and sciolists into the keeping of men distinguished for their acquirements.

What is being sought to be accomplished for the whole profession the medical corps of the navy has aspired to make the patent of its own nobility, and its board of examiners may justly claim recognition for its pioneer efforts to exclude from fellowship the unworthy and incompetent.

ALBERT L. GHON, M. D.,

Medical Director U. S. Navy.

1736 I STREET, WASHINGTON, D. C.

UNITED STATES MARINE HOSPITAL SERVICE.

The following extract from the regulations governing the Marine Hospital Service is published as showing who are eligible for examination:—

(24.) Original appointments of medical officers in the United States Marine Hospital Service will be made to the grade of assistant surgeon only.

(25.) Medical officers in the Marine Hospital Service will in no case be appointed to any particular station, but to the general service, being subject to change of station as the exigencies of the service may require, and shall serve in any part of the United States wherever assigned to duty by the secretary of the treasury.

(26.) No person will be appointed an assistant surgeon whose age is less than twenty-one or more than thirty years, and, as a preliminary to a recommendation for appointment, the applicant must have graduated in medicine at some respectable medical college, and must pass a satisfactory physical and professional examination before a board of surgeons of the Marine Hospital Service, which will be convened from time to time, for that purpose, by the secretary of the treasury.

(27.) The passing of an examination must not be considered as giving assurance of appointment, as the department will select those of the highest attainments in case there should be more candidates than vacancies.

(28.) No qualified candidate will be eligible for appointment more than one year. If not appointed within that time, he may, if he desires, be reexamined, when, if successful, he will take position with the class last examined.

(29.) An applicant failing at one examination may be allowed a second examination, after one year, but not a third.

(30.) Assistant surgeons, after three years' service, at least one year of which shall have been at a United States marine hospital, shall be entitled to an examination for promotion to the grade of passed assistant surgeon. The application for this examination must be accompanied with testimonials of correct

department and habits of industry from the surgeons with whom they have served, and the applicant must be familiar with these regulations.

(31.) A vacancy in the grade of surgeon will be filled by promotion from among passed assistant surgeons.

All applications should be addressed to the surgeon-general of the service at Washington, D. C.

We extract from the annual report for 1880 the following, relative to the character of the examinations:—

"There is probably no branch of the public service to which the rules laid down by the civil-service regulations of 1872 can be more easily applied. The experience of this office has not only demonstrated their practicability, but has proved entirely satisfactory. The following table shows the number of candidates examined for the past five years:—

Year.	No. of Candidates.	No. of branches in which examined.	Passed.	Rejected.	Percentage of Rejections to whole No. examined.	No. Invited to appear for Examination.
1875	11	10	8	3	27 3-11ths.	—
1876	13	10	8	5	28 6-13ths.	—
1877	18	10	6	12	66 2-3ds.	38
1878	11	10	3	8	72 8-11ths.	35
1879	29	10	6	23	79 9-29ths.	52
1880	23	10	4	19	82 14-23ds.	43

The marking adopted has been in accordance with the scale recommended by the Board of Civil-service Examiners of the treasury department in their report dated January 21, 1873.

The scale is as follows:—

Best possible	100	Somewhat bad.....	40
Extremely good	90	Bad	30
Very good	80	Very bad	20
Good	70	Extremely bad.....	10
Somewhat good.....	60	Worst possible.....	0
Indifferent	50		

In an average examination the only branch in which the "best possible" may be obtained is of course anatomy, but it may be occasionally reached in the answers to certain questions in several branches. In the first four years during which these examinations were held, no examination in the common-school branches was made, but during the last year an oral examination in arithmetic, physics, and history has been added. Proficiency in these branches, together with a "personal history" showing the candidate to have had good advantages in schools or experience in hospitals, increases the marking under the heading "general aptitude." This heading is the one most likely to be misinterpreted by the enemies to the system, or by the friends of disappointed candidates, and yet it has been found impracticable to discontinue it. Under this heading is included the preliminary education of the candidate, his health, his personal appearance, as to neatness or slovenliness, as well as the general fitness for the service, as shown by examination-papers as a whole. The following is given as a specimen of the examination papers, and shows the scope of the examination. The questions were propounded at the session of the board held in April, 1879:—

Anatomy. (1.) Name the bones of the cranium, the foramina at its base, and the structures transmitted through them. (2.) Give the origin and distribution of the trigeminal nerve. (3.) Describe the regions of the abdomen, and name the viscera contained in each. (4.) Name the parts divided in a circular amputation of thigh at middle of Scarpa's triangle.

Physiology. (1.) Give the histology and function of the kidneys. (2.) How is the nutrition of muscular tissue effected? (3.) Give the normal constituents of bile, blood, and gastric juice. (4.) Give functions of sympathetic system and spinal cord.

Chemistry. (1.) Describe the atom and molecule, and state what is meant by atomic weight and molecular weight of an element. (2.) Give the chemical reaction that occurs in an active galvanic battery composed of carbon and zinc plates and the fluid made by dissolving bichromate of potassium in dilute sulphuric acid. (3.) Describe the physical and chemical properties of alum, and give its formula. (4.) Mention the different forms of carbon, and give brief description of each, and name the most important combinations of this element.

Practice of Medicine. (1.) Describe the process of inflammation. (2.) Give, briefly, the symptoms and treatment of cerebro-spinal fever. (3.) What are the causes of anasarca? (4.) Give the differential diagnosis between eczema, herpes, and rupia.

Hygiene. (1.) Give, briefly, your views as to the best method of lighting, heating, and ventilating hospital wards. (2.) Assuming that the water supply of a hospital contains matters deleterious to health, what method would you use to discover the impurities, and to eliminate them? What, in your opinion, are the necessary articles and proper proportions of the same, for a hospital ration? (4.) What are the principal substances used as disinfectants and deodorizers, and what is their mode of action?

Surgery. (1.) Give the causes of compression and concussion of the brain, and their differential diagnosis and treatment. (2.) What are the causes of popliteal aneurism? (3.) Describe the treatment of compound comminuted fracture of the leg. Give the best method of management, and the possible dangers of the injury. (4.) Mention the symptoms, complications, and treatment of penetrating wounds of the chest and of the abdomen.

Obstetrics. (1.) Describe the foetal circulation and the changes taking place therein at birth. (2.) Give the causes and treatment of post-partum hemorrhage. (3.) Give the causes, symptoms, and treatment of puerperal convulsions. (4.) Give the differential diagnosis between abdominal tumors, spurious and true pregnancy.

One day is devoted to clinical examinations at a hospital, which, with an oral examination, concludes the exercises.

Foreign Schools.¹

GREAT BRITAIN AND IRELAND.

THE number of examining bodies in the United Kingdom which grant degrees and diplomas capable of registration under the Medical Act of 1858 is nineteen; and the registrable qualifications obtainable from them amount to fifty-seven.

The following is a general summary of the conditions required on the part of candidates for examination. The regulations of the examining bodies are, with very few exceptions, framed in accordance with the resolutions and recommendations of the General Medical Council.

Every medical student is required to be registered at the office of the General Medical Council, prior to which he must have passed an examination in subjects of general education. As evidence of this are recognized: (1.) The possession of a degree in arts of a university of the United Kingdom or of the colonies, or of some university recognized by the Medical Council. (2.) A certificate of having passed an examination in subjects of general education conducted by some one or other of the educational bodies, a list of which is given with the Recommendation of the General Medical Council. The Medical Council recommends that no such certificate should be accepted by any of the licensing boards, unless it testify that the candidate has been examined in the following subjects: (1.) The English language, including grammar and composition. (2.) Arithmetic, including vulgar and decimal fractions, and Algebra, including simple equations. (3.) Geometry, the first two books of Euclid, or the substance thereof. (4.) Latin, including translation and grammar. (5.) One of the following subjects at the option of the candidate: Greek; French; German; Elementary Mechanics of Solids or Fluids, meaning thereby mechanics, hydrostatics, pneumatics, and hydraulics. [On and after January 1, 1882, the following subjects will be required: (1.) English Language, including grammar and composition. (2.) English History. (3.) Modern Geography. (4.) Latin, including translation from the original and grammar. (5.) Elements of Mathematics, comprising (a) Arithmetic, including vulgar and decimal fractions; (b) Algebra, including simple equations; (c) Geometry, including the first two books of Euclid, or the subjects thereof. (6.) Elementary Mechanics of Solids and Fluids, comprising the elements of statics, dynamics, and hydrostatics (this subject may be passed either as preliminary, or before, or at the first professional examinations. (7.) One of the following optional subjects: (a) Greek; (b) French; (c) German; (d) Italian; (e) any other modern language; (f) Logic; (g) Botany; (h) Elementary Chemistry.] The preliminary examination having been passed, the student should at once register, as the commencement of the course of professional study is not recognized as dating fifteen days earlier than the date of registration. Forms of such registration are supplied by the licensing bodies and at the schools and hospitals.

After passing the preliminary examination, the student may commence his medical education in one of the following ways (according to the regulations of the licensing body with which he intends to become connected): (1.) By attendance for one year on the practice

¹ Hardwicke on Medical Education.

of a provincial hospital or other public institution recognized for this purpose. (2.) As the pupil, for one year, of a legally qualified surgeon, holding sufficient public appointments to afford such opportunities of practical instruction as shall be satisfactory to the authorities. (3.) By entering at once at a recognized medical school.

The minimum period of medical study required is forty-five months from the date of registration as a student, of which time at least two years and a half must be passed at a recognized medical school. For the degrees of the universities (except that of London) the candidate is required to spend a portion of the time of medical study at the university which grants the degree, or at a college in connection therewith.

To obtain a degree, diploma, or license, two examinations at least in professional subjects must be passed. The first examination may be completed at or before the close of the second year of professional study, and embraces the following subjects: (1.) Chemistry and Chemical Physics. (2.) Anatomy. (3.) Physiology. (4.) Materia medica and Pharmacy. The second or final examination, which must not be passed until the completion of the fourth year of study, comprises: (1.) Pathology (including morbid anatomy). (2.) Medicine (including medical anatomy, clinical medicine, and therapeutics). (3.) Surgery (including surgical anatomy and clinical surgery). (4.) Midwifery. (5.) Forensic Medicine. This arrangement is of course subject to some variation; but the general principle of examining first in the elementary and afterwards in the practical subjects is invariably followed. Some of the examining bodies — such as the universities in Scotland — divide the examinations into three or four parts.

The medical schools in London are those of St. Bartholomew's, Charing Cross, St. George's, Guys, the London, St. Mary's, the Middlesex, St. Thomas's, and Westminster Hospitals; and the Medical Faculties of King's and University colleges. To these may be added the London School of Medicine for Women, with which the Royal Free Hospital is connected for the purpose of clinical instruction, and Mr. Thomas Cooke's School of Anatomy and Surgery.

In the provinces in England, there are the medical departments of Queen's College, Birmingham, Owens College, Manchester, and the Medical College of the University of Durham, at Newcastle-on-Tyne; together with medical schools at Bristol, Leeds, Liverpool, and Sheffield. The Universities of Oxford and Cambridge do not profess to give a complete education; in fact, there is no medical school at Oxford; but instruction in many branches is provided for at Cambridge.

In Scotland, the medical schools in which a complete course of professional education is given are those attached to the Universities of Aberdeen, Edinburgh, and Glasgow, the Extra-Academical School in Edinburgh, and the Anderson's College and the Royal Infirmary School of Medicine in Glasgow.

In Ireland the medical schools are, the School of Physic in Ireland, the School of the Royal College of Surgeons of Ireland, and the colleges at Belfast, Cork, and Galway, in connection with the Queen's University in Ireland. There are also several medical schools in Dublin, namely, the Carmichael College of Medicine and Surgery; the Catholic University; Dr. Steevens's Hospital and Medical College; and the Ledwich School of Anatomy, Medicine, and Surgery.

FRANCE.

Degrees in medicine of the University of France are conferred by the faculties of Paris, Montpellier, Nancy, Bordeaux, Lille, and Lyons, under regulations laid down by the government.

(1.) The studies necessary for obtaining the degree of doctor of medicine last four years; during the first three years they may be carried on either in the faculties, in the *école de plein exercice*, or in the preparatory schools of medicine and pharmacy. The studies of the fourth year can only be made in a faculty or in an *école de plein exercice*.

(2.) The candidates must produce, when they take the first inscription, the diploma of bachelor of sciences, limited as regards the mathematical part. They must undergo five examinations and defend a thesis. The second, third, and fifth examinations are divided into two parts. The *examens de fin d'année* are suppressed.

(3.) The five examinations are on the following subjects. First examination: physics, chemistry, medical natural history. Second examination: first part, anatomy and histology; second part, physiology. Third examination: first part, external pathology (surgery), midwifery, operative surgery; second part, internal pathology (medicine), general pathology. Fourth examination: hygiene, legal medicine, therapeutics, materia medica, and pharmacology. Fifth examination: first part, clinical surgery and obstetrics; second part, clinical medicine, practical demonstrations in pathological anatomy, and a thesis on a subject chosen by the candidate.

(4.) The first examination takes place after the fourth inscription and before the fifth; the first part of the second examination after the tenth inscription and before the twelfth; and the second part after the twelfth inscription and before the fourteenth. The third examination cannot be passed until the end of the sixth *trimestre* of study. Any candidate who does not pass the first examination in November, at the latest, will be put back to the end of the scholastic year, and will not be permitted to take out any inscription during the course of that year.

(5.) Candidates for the doctorate, pupils of *écoles de plein exercice* or of the preparatory schools, are examined by the faculties at the periods fixed in the preceding article. They may, however, defer the first examination until after the twelfth inscription. In that case they must pass the second examination before the thirteenth inscription, and, from the commencement of the second year of study, are subjected to interrogations at the end of six months, the results of which are transmitted to the faculties, to be taken into account in the examinations for the doctorate.

(6.) The inscriptions for *officier de santé* cannot be converted into inscriptions for the doctorate, in the case of pupils actually studying; but this conversion may be permitted in the case of *officiers de santé* who have practiced medicine for at least two years.

(7.) Practical work in the laboratory, dissection, and residence near the hospitals are obligatory. Each annual period of laboratory work and dissection comprises six months' course, or semestre. Residence near the hospitals must not continue less than two years.

(8.) Every candidate, who, without an excuse admitted by the jury, does not answer when his name is called, on the day of which notice has been given to him is sent back for three months, and forfeits the fees which he has paid.

(9.) The fees to be paid by candidates for the degree of doctor in medicine are fixed as follows:—

Sixteen inscriptions at 32 francs 50 centimes each	520 francs.
Eight examinations at 30 francs	240 francs.
Eight certificates of proficiency at 25 francs	200 francs.
Expenses of materials for practical study, first year, 60 francs; second and third years, each 40 francs; fourth year, 20 francs	160 francs.
Thesis	100 francs.
Certificate of proficiency	40 francs.
Diploma	100 francs.
Total	1360 francs.

(10.) The fees paid by the pupils of the faculties go to the public treasury. The fees paid for inscriptions and for practical work by the pupils of the *écoles de plein exercice* and the preparatory schools go to the municipal treasuries.

A foreigner holding medical qualifications to practice medicine, if desirous of obtaining the degree of the University of France, must show to the minister of public instruction his diploma, and the certificates of the course of study which he has undergone in his own university or medical school. The minister, if satisfied, will authorize the candidate to present himself for the five final examinations (*examens de réception*). These are conducted in the French language. The fees are as follows: each examination 90 francs = 450 francs; thesis, 240 francs; fifteen inscriptions, 520 francs; three *examens de fin d'année*, 90 francs; diplomas of *bachelier ès lettres et ès sciences*, 100 francs; in all 1400 francs. It will be seen that the candidate has to pay all the fees, although exempted from the necessity of passing the preliminary examinations and those for the *bacheliers ès lettres et sciences*.

Medical education in France is under the control of the state, and is given in the faculties of medicine and pharmacy, the *écoles de plein exercice*, and the preparatory schools of medicine and pharmacy.

The Faculties are six in number: three—those of Paris, Montpellier, and Nancy, are composed of two distinct schools of Medicine and Pharmacy; the others, at Bordeaux, Lille, and Lyons, are called mixed Faculties of Medicine and Pharmacy. They confer, besides the same diplomas and certificates as the other schools, the diplomas of doctor in medicine and *pharmacien* and midwife of the first class.

There are two *écoles de plein exercice*, namely, at Nantes and at Marseilles. They are entitled to give the same certificates as the preparatory schools; but candidates for the doctorate may take out sixteen inscriptions in them.

The Preparatory Schools are entitled to give diplomas or certificates of *Officier de santé* and *Pharmacien*, herbalist, or midwife, of the second class. Candidates for the doctorate can study in them three years, and take out twelve inscriptions. There are preparatory schools at Algiers, Auiens, Angers, Arras, Caen, Clermont, Ferrand, Dijon, Grenoble, Limoges, Poitiers, Reims, Rennes, Rouen, Toulouse, and Tours.

The following are the conditions laid down by the French government for the recognition of a faculty of medicine: The city in which the school is established must pay a proper share of the expenses. There must be seventeen professorships, namely, anatomy, physiology, internal physiology (medicine), general pathol-

ogy and pathological anatomy, hygiene and forensic medicine, operative surgery, therapeutics, materia medica, botany and zoology, medical chemistry, medical physics, pharmacy, and clinical midwifery,—each with one professor; and two professors each of clinical medicine and clinical surgery. There must also be eight assistant professors: two each for the natural sciences, medicine, and surgery, and one each for obstetrics and for anatomy and physiology. These assistants are selected by *concours*, and appointed for ten years.

The School of Medicine in Paris is open not only to the French public, but to all who wish to attend the courses and take degrees. Great facilities are afforded to British and foreign students for the prosecution of their studies, all lectures being given gratuitously, and no payment being required for hospital attendance. For dissections, however, a payment of 30 francs or more is expected from each student.

The medical sessions begin for winter on October 15th, and for summer on April 15th, of each year.

The instruction in the faculty of medicine in Paris is given by the following professors: M. Sappey, Anatomy; M. Robin, Histology; M. Bécclard and M. Richat (agrégé) Physiology; M. Wurtz and M. Herminier (agrégé), Medical Chemistry; M. Baillon and M. de Laessan (agrégé), Natural History; M. Gavarret and M. Garid, Medical Physics; M. Regnaud, Pharmacology; MM. Jaccoud, and Peter, and Dicuclafoy (agrégé), Internal Pathology or Medicine; M. Trélat and M. Berger (agrégé), External Pathology or Surgery; M. Guyon, Surgical Pathology; M. Le Fort, Practical Surgery; M. Hayem, Materia Medica and Therapeutics; M. Charcot and M. Ollivier (agrégé), Pathological Anatomy; M. Pajot and M. Piuard (agrégé) Midwifery; M. Bouchardat, Hygiene; M. Brouardel, Forensic Medicine; M. Bouchard, General Pathology and Therapeutics; M. Vulpian, Comparative and Experimental Medicine; MM. G. Sée, Lasègue, Hardy, Potain, Clinical Medicine; MM. Gosseclin, Richet, Verneuil, Trélat, Clinical Surgery; M. Depaul, Clinical Midwifery; M. Panas, Clinical Ophthalmology; M. Parrot, Diseases of Children; M. Laboulbène, History of Medicine; M. Ball, Diseases of the Mind and Nervous System. Supplementary courses are also given on Diseases of the Skin, Diseases of Children, Venereal Diseases (M. Fournier).

There are laboratories for Normal Histology (under the charge of Robin); Physiology (Bécclard); Pathological Anatomy (Charcot); Experimental Pathology (Vulpian); Therapeutics (Hayem); Biological Chemistry (Gautier); Pharmacology (Regnaud). The sphere of these laboratories is limited owing to imperfect accommodations and means; they are used chiefly by medical men and students preparing their theses.

GERMANY.

In the German empire there are twenty universities which possess a medical faculty and grant degrees in medicine; namely, those of Berlin, Bonn, Breslau, Erlangen, Freiburg im Breisgau, Giessen, Göttingen, Greifswald, Halle, Heidelberg, Jena, Kiel, Königsberg, Leipzig, Marburg, Munich, Rostock, Strasburg, Tübingen, and Würzburg.

No one can legally practice medicine in this empire unless he has passed the Staats-Examen board. The law forbids any one to call himself *Arzt* (physician) unless he has passed the State Board, or doctor unless

he has passed the examinations at some university, and thereby acquired the degree. The doctor who has not passed the State Board is not a licensed physician and may hold no appointment; and if he practice has no power or right to insist on payment for his services. The physician licensed by the State Board, on the other hand, is not allowed to call himself "doctor," unless he has passed a university examination. The practitioner who is neither doctor nor physician practices at his peril; for though he is not forbidden by law to do so, yet, if any mishap occur from his ignorance, he is punished not only by fine but by imprisonment for a period varying from six months to ten years.

The expenses of passing the State Board are less than half of those for the faculty of a university, and the examination is more exclusively practical; hence it is selected by the poorer students, who seek only a rural practice. The majority of students pass both the university and the state examinations, and this is especially necessary for those who aspire to any medical office.

No medical diploma, either from a university or otherwise, can be obtained in Germany without a gymnasial certificate, to obtain which an examination must be passed at a German gymnasium (public school) in Greek, Latin, at least one modern language besides German, logic, the physical sciences, and mathematics. A candidate who cannot present this, or an equivalent certificate, must pass a preliminary examination in those subjects.

The number and character of professional chairs in the medical faculties vary greatly in the different universities; but in all we find three classes of teachers, namely, professors, extraordinary or assistant professors, and *privat-docents*.

The professors are appointed for life, and at the end of thirty years' service can retire on a pension; they receive a fixed salary from the state or university, a part of the revenue derived by the medical faculty from certain fees, and their lecture fees from the students. The fixed salary is occasionally increased, according to the success and reputation of the professor. Any doctor in medicine may be a candidate for a vacant chair, the selection being made by the Minister of Public Instruction from a list of names recommended by the faculty.

The extraordinary or assistant professors are appointed in like manner from among the *privat-docents*. As a rule, their compensation comes only from students' fees, but occasionally a small fixed salary is allowed.

The position of *privat-docent* is accessible to all doctors of medicine, and the number is unlimited. Their compensation is from students' fees, and they may not underbid the regular professor. At some universities they are furnished with rooms, and given a share of the clinics; at others they receive little or no assistance.

There are no independent schools in Germany. No one can open a course on his own responsibility, and the universities have alone the power to confer academic grades. The system of *privat-docents*, however, compensates in a great measure for this want of freedom. As the test of fitness for a degree in the university, or for the position of a practitioner in the state, is mainly the ability to pass certain examination, and as the salaries of the professors are guaranteed by the state, it is evident that it makes little dif-

ference as to precisely when, where, or how the student gets his information, provided only that he really gets it.

There is, therefore, little objection to free, or, as it is sometimes called, "extramural teaching," and hence young men of ability can establish themselves as private teachers, demonstrators, etc., in the immediate vicinity of the universities, relying on their own talents and tact to secure pupils. These are the *privat-docents*, much of whose teaching consists in giving short courses, of from six to eight weeks' duration, on special subjects. These *privat-docents* are subject to certain regulations, and follow in a general way the teaching and directions of the professor of the special branch to which they attach themselves; they are understood to be in training for professorships, and, if they show marked ability as teachers or as investigators, their promotion may be very rapid.

The course of study at the German universities varies according to the requirements for the particular medical degree, but in no case is it less than three years. At some the course extends over four years. The following lectures are the least which will be accepted by any of the university faculties, and may be taken in whatever order the student may wish. The courses occupy nine and a half months in each year. For one year: chemistry, six hours weekly; physics, four hours weekly; zoölogy and comparative anatomy, three hours weekly; botany, three hours weekly; mineralogy and geology, two hours weekly; anatomy, histology, and preparation of specimens, ten hours weekly; physiology and laboratory work, eight hours weekly; general pathology, pathological anatomy, and practical work, six hours weekly; pharmacology and toxicology, two hours weekly. For two years: special pathology and medical clinic at hospital, ten hours weekly; general and special surgery, hospital clinics, and operating, ten hours weekly for one year, or five hours weekly for two years. This course may not be taken at the same time as the previous medical course. Obstetrics and gynecology, with clinics, three hours weekly for one year; eye and ear clinics, use of ophthalmoscope, operations, four hours weekly for one year; forensic medicine, two hours weekly for one year.

The professors receive fixed salaries, varying from \$600 to \$2400 annually, and increased every ten years by the addition of from \$100 to \$250. The students' fees for the entire course vary in different schools from \$180 to \$260.

UNIVERSITY OF BERLIN.

The institutions for clinical treating connected with the university are: Professor von Langenbeck's Clinic for Surgery; the University Polyclinic (Dr. J. Meyer); the Ophthalmic Polyclinic (Dr. Schweigger); the Aural Clinic (Dr. Lucac); the Obstetric Clinic (Dr. Schroeder); the Institute for Practical Instruction in State Medicine (Dr. Liman); and in the Charité Hospital, the Medical Clinic (Dr. Frerichs); the Clinic for Elementary Medical Instruction (Dr. Leyden); the Surgical Clinic (Dr. Bardeleben); the Ophthalmic Clinic (Dr. Schweigger); the Obstetric Clinic (Dr. Gussow); the Gynecological Clinic (Dr. Schroeder); the Clinics for Diseases of the Skin and Syphilis (Dr. Lewin), for Diseases of Children (Dr. Henoch), and for Diseases of the Mind and Nervous System (Dr. Westphal). The Pathological Institute is under the direction of Professor Virchow; the physiological

laboratory under that of Professor Du Bois-Reymond; and the chemical laboratory under that of Professor Hofmann.

SWITZERLAND.

In Switzerland degrees in medicine are granted in the universities of Basle, Berne, Geneva, and Zurich. These degrees do not confer a license to practice, for which a separate examination is required.

AUSTRIA.

The universities of the Austro-Hungarian Empire which possess medical faculties and grant degrees in medicine are: Agram (Croatia), Gratz (Styria), Innsbrück (Tyrol), Cracow, Lemberg (Galicia), Pesth (Hungary), Prague (Bohemia), and Vienna.

All the universities are under government control, and the degree of doctor of medicine obtained at any of them alone gives the right to practice medicine in the empire.

The course of study required of candidates for the degree of doctor of medicine in the universities of the Austrian Empire extends over five years, or five winter and five summer terms or semesters. The following arrangement is recommended by the government. (The first, third, fifth, seventh, and ninth are winter semesters; the others are summer semesters.) First semester: systematic anatomy; experimental physics; inorganic chemistry; general botany; dissections. Second semester: systematic anatomy (second part); experimental physics (second part); organic chemistry; special botany; practical introduction to chemical analysis; practical introduction to the use of the microscope. Third semester: physiology; histology; medical chemistry; zoology; dissections. Fourth semester: physiology (second part); embryology; exercises in physiology, in histology, and in medical chemistry. Fifth semester: general pathology and therapeutics; pharmacology; pathological anatomy; pathological histology; post-mortem examinations; practical introduction to the physical examination of patients. Sixth semester: pathological anatomy (second part); special pathology, therapeutics, and clinic of internal diseases; special surgical pathology, therapeutics, and clinic; post-mortem examinations; exercises in pathological histology. Seventh semester: special pathology, therapeutics, and clinic of internal diseases; special surgical pathology, therapeutics, and clinic; diseases of the eye; exercises in surgical anatomy (operations). Eighth semester: internal diseases; surgery or diseases of the eye; surgical operations (surgical anatomy). Ninth semester: internal diseases; surgery; theory and practice of obstetrics and gynecology; forensic medicine (exercises in obstetric operations); medico-legal exercises. Tenth semester: clinics of diseases of children, of diseases of the skin, and of syphilis (obstetrics and gynecology); exercises in obstetric operations (medico-legal exercises). Of the subjects included in parentheses one course only is required, which may be attended in either a winter or a summer term, at the option of the student.

The examinations are public, and each member of the commission examines the candidate for a quarter of an hour. He is required to undergo three examinations for his degree.

The great clinics on medicine, surgery, etc., are conducted during the two sessions, from the middle of October to the middle of March, and from the middle of April to the end of July. They are under the immediate

direction of the professors of the medical faculty, and constitute, of course, an essential part of the curriculum of study for the ordinary Austrian student.

The special courses of instruction are most numerous during the regular academical sessions, but there are always some going on, even in August and September. They last usually for from four to eight weeks. The courses are given for the most part by private lecturers and the professors' assistants, and the material for them is derived from the wards of the clinical professors.

CANADA.

The following are the medical examining bodies and schools in the several provinces constituting the Dominion of Canada.

NOVA SCOTIA. — University of Halifax Faculty of Medicine; Halifax Medical College.

ONTARIO. — College of Physicians and Surgeons of Ontario; Medical Faculty of the University of Victoria College, Coburg; Medical Faculty of Queen's College, Kingston; Royal College of Physicians and Surgeons, Kingston; Medical Faculty of the University of Ottawa; Toronto University Faculty of Medicine; Trinity College Faculty of Medicine, Toronto; Toronto School of Medicine; Trinity Medical School.

QUEBEC. — College of Physicians and Surgeons of Quebec; Bishop's College University Faculty of Medicine, Montreal; Laval University, Montreal and Quebec; McGill University Faculty of Medicine.

MCGILL UNIVERSITY OF MEDICINE.

The matriculation examination comprises the following subjects: English language (including grammar and composition); arithmetic (including vulgar and decimal fractions); algebra (including simple equations); geometry (first two books of Euclid); Latin (translation and grammar); and one of the following optional subjects: Greek, French, German, natural philosophy, including mechanics, hydrostatics, and pneumatics. Graduates in arts of recognized universities are not required to submit to the matriculation examination; and a certificate of having passed this examination before the College of Physicians and Surgeons of Ontario or of Quebec is accepted.

No one can be admitted to the degree of doctor of medicine and master of surgery who shall not, in this or in some other university, college, or medical school, approved of by this university, either have attended lectures for at least four six-months' sessions, or studied medicine during at least four years, and during that time have attended lectures for at least three six-months' sessions.

Candidates for the final examinations must furnish testimonials of attendance on the following courses: anatomy, chemistry, materia medica, and pharmacy, institutes of medicine, principles and practice of surgery, midwifery and diseases of women and children, theory and practice of medicine, practical anatomy, clinical medicine, clinical surgery, — each two six-months' courses; medical jurisprudence, — one course of six months, or two courses of three months; practical chemistry, botany or zoology, hygiene, — each one three-months' course duration; no less than twenty-five demonstrations upon microscopic anatomy, physiology, and pathology. Testimonials equivalent to, though not precisely the same as, those above stated may be presented and accepted. The candidate must have attended during eighteen months the practice of the Montreal General

Hospital, or that of some other approved hospital, and have compounded medicines for six months. He must also have attended for at least six months the practice of the university or other approved lying-in hospital, and have attended at least six accouchements.

Every candidate for examination must have attended at least one session at this university, and one full course of all the branches included in its curriculum.

JAPAN.

In June, 1876, the number of medical practitioners in the returns of two cities and forty-three prefectures was estimated at 23,281, about twenty-one per cent. of whom were practicing medicine according to the Western system, and all of the remainder either according to the mixed systems of China and the West to that of China and Japan, or to the pure Japanese one.

Knowing that it would be impossible to make the change to the new methods at once, and thus to secure uniformity, the government adopted a politic course. It strongly recommended to the young medical students to pursue only the most approved course of study, and to those now in practice to continue as in the past, or to make such changes as the exigencies or advantages of their practice might afford. In 1876 the late home minister, Okubo, issued a notification "that the examination of candidates for a certificate to practice medicine in accordance with the following regulations shall be introduced into every prefecture as soon as the condition of medical men in each prefecture shall admit:—

Regulations for the examination of Candidates. Article I. Any one desirous to become a medical practitioner shall be required to apply for a certificate, which shall be given only after the prescribed examination has been passed satisfactorily.

Note. Any one who has been at the time of the issue of these regulations practicing medicine shall not be obliged to subject himself to an examination. The local authorities shall therefore take the proper measures to distinguish such medical practitioners from those who have been licensed after a satisfactory examination. . . . The subjects for examination for candidates are the general principles of natural philosophy, of anatomy, of physiology or pathology, of pharmacology, and the theory and practice of medicine and surgery. . . .

Article III. The examination shall be held at a convenient place, such as the local government office or public hospital; and the results shall be reported to the Home Department, which shall grant the certificates. . . .

In June, 1877 (the date of the last published report), there was in Japan a population of 32,812,116, of whom 31,298 were medical practitioners (this enumeration includes all of the prefectures except Kagoshima), giving a proportion of 0.91 to the thousand of population. Of this army of "doctors," 20,568 were followers of the Chinese system; 1998 mixed and non-classified; 6402 the Western system; and 200 licensed after the prefectural examination. Though no official reports are at hand, yet the testimony of the native physicians in Hokkaido and at the line of hospitals in North Nippon is to the effect that Western medicine has made greater progress during the past three years than at any previous period; that the number of the Chinese school of doctors is decreasing; that the people are slowly being educated up to the advantages and benefits of the new treatment, though a very large number still adhere to the old methods; that local hospitals and dispensaries are springing up in all parts of the interior; and that the Western ideas of hygiene and sanitation are receiving increasing attention from all the local authorities.

— Dr J. C. Cutler

Medical and Surgical Journal.

THURSDAY, OCTOBER 13, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

NO. 4 PARK STREET, BOSTON, MASS.

THE PROGRESS OF MEDICAL EDUCATION.

In nature and in art, growth and development of a permanent and wholesome character are, as the rule teaches us, slow. Matters pertaining to medical education certainly are no exception to this rule. The annual periods marked by great changes are rare, and these great changes are but the sudden expression of numerous single influences which as such attracted less attention.

The appearance of the educational number of the JOURNAL last year was coincident with the first formal announcement by many schools of changes in the course of instruction toward a higher standard. The necessity for such a step has been long enough apparent, and the demand for the changes had at last become sufficiently urgent to convince several faculties that it was not risking too much to take the step. In our remarks on this subject we then said:—

"A glance beneath the surface at the work done by our medical schools during the past decade in raising the standard of education shows an amount of improvement, even among those colleges which have not adopted a new plan, or joined any special association, that one would hardly expect to find who had not followed closely the process of evolution so rapidly developed since an onslaught was made upon the old system, which had maintained undisputed sway for nearly a century. A course of instruction which ten years ago was considered amply sufficient to enable the brain of Young America to digest the art and a handsome allowance of the science of a great profession, a course which received the indorsement of the leading men in the country, would now be disclaimed, if not openly despised, by any faculty having pretensions to 'standing.' The time occupied then in obtaining a degree would hardly suffice now to enable the student to complete satisfactorily a preparatory course of study. It was thought by students at that time evidence of unusual talent and an enviable record for one to get his degree in the smallest possible number of months. A man who 'hung round' a medical school for three years was looked upon as a sort of dunce. At the present day, even at many of the schools which still hold on to the old go-as-you-please plan of study, it is thought quite the thing not to get through your anatomy, chemistry, and physiology until well into your second year, and 'four-year men' are, we are happy to say, not only the 'very latest style,' but also quite a popular one."

No very radical changes among the schools were

to be expected after those announced last year. Those then advancing their requirements have been steadilying themselves in their new positions; and others, meanwhile, have thought it well to assume a certain amount of a virtue which has not yet proved fatal, and in some cases has really been immediately profitable, to its actual possessors. Bellevue Hospital Medical College is the only one, we believe, which has avowedly "advanced to the rear" within the twelve months. The faculty of this school reluctantly, though quickly, came to the conclusion that it was improper for them to jeopardize its interests by an obligatory three years' course. Attendance upon only two years' courses of lectures, and only one of these at Bellevue, is now again, as of old, the requirement for its diploma. Recognition is given to higher aspirations by facilities for a third year of study to those desiring it.

The regulation of the practice of medicine by State legislation has received comparatively little attention, and progress can scarcely be recorded. Such regulation, whether of a positive or negative character, must always have a certain bearing upon medical education. The year's experience with registration laws is not especially encouraging. Between a failure to register, a failure to bring charges, and a failure to convict, these laws appear to more advantage on paper than in operation. Since 1859, North Carolina has regulated the practice of medicine within her borders through a Medical Licensing Body. We have been assured that the result is satisfactory to the profession, and reproached with not calling attention to the law. The *North Carolina Medical Journal*¹ says:—

"By the North Carolina law the possession of a diploma does not qualify an applicant to practice, it matters not how celebrated the college may be from which it is obtained. According to the law, any person can apply for a license to practice medicine provided he can give satisfactory evidence that he is twenty-one years of age, and of good moral character; but he must pass a satisfactory examination in Anatomy, physiology, surgery, pathology, medical hygiene, chemistry, pharmacy, materia medica, therapeutics, obstetrics, and the practice of medicine, to be licensed.

"The defect in the law is that there is no penalty clause except this: 'Any person who shall practice medicine or surgery in this State without having first applied and obtained license from the Board of Examiners, shall not be entitled to sue for or recover before any magistrate or court any medical bill for services rendered.' While it would be an improvement to have a more direct and onerous penalty clause, the omission is not so great when other advantages are considered. The Board of Examiners are elected by ballot from the members of the Medical Society of North Carolina, and no one can be a member of the State Medical Society without he has the license of the Board of Examiners, or was a practitioner anterior to 1859.

"With this foundation the moral influence is so great that but few young men are willing to ostracize them-

selves from legal professional intercourse by neglecting to obtain the State license. Every year the number applying for license is larger, and, by the way, every year the percentage of licenses granted is smaller.

"The good effects of this law have been noticed for many years, and it is growing stronger in the confidence of the people. The man who would have stricken the law from the statute books, by a resolution offered in the legislature, had his estate protected by it from the rapacity of a quack.

"Moreover, in North Carolina there are exceedingly few irregular physicians, except the usual percentage of morbid growths from the regular stock, and up to this time no eclectic or homoeopath has applied for license."

The necessity for some legal regulation of the practice of medicine will probably sooner or later become apparent, though it may require an even stronger impulse than the revelations of the past year concerning the traffic in bogus diplomas to make it so. The different States will probably awake to this necessity at different periods and under different circumstances, and we may expect a variety of bills and of subsequent failures or laws.

The study of anatomy has still to be pursued in some States under very great difficulties. An anatomical bill has been passed in Maine within the year, which makes lawful possession of material for dissection a little less impossible than previously.

Regarding the State medical societies, as a possible means of furthering higher medical education, we hope at a not distant day to devote some space in the JOURNAL to their form of organization in different States. The demands upon the knowledge of medical men are unquestionably increasing in severity all over the world, and with us no less than elsewhere. Provision must be made for meeting these demands and expectations as they arise, whether by the schools, by the legislatures, by the State medical societies, or by the aid of all.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM OCTOBER 1, 1881, TO OCTOBER 7, 1881.

BYRNE, C. C., major and surgeon. To proceed from Wilcox to Camp Thomas, A. T., and report to the commanding officer for duty in the field. Field orders No. 4, Department of Arizona, September 9, 1881.

BROWN, HARVEY E., major and surgeon. Granted leave of absence for four months. S. O. 220, A. G. O., September 29, 1881.

CLEARY, P. J. A., captain and assistant surgeon. Granted leave of absence for six months on surgeon's certificate of disability, with permission to apply for six months' extension, if necessary. S. O. 224, A. G. O., October 4, 1881.

KOERPER, E. A., captain and assistant surgeon, now awaiting orders at Philadelphia, Pa. To report in person to the commanding general, Department of the East, for assignment to duty. S. O. 222, A. G. O., October 1, 1881.

KING, WILLIAM H., captain and assistant surgeon. To proceed without delay to Fort Trumbull, Conn., and report to the commanding general for temporary duty. S. O. 176, Department of the East, October 3, 1881.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held on Monday evening, October 17th, at eight o'clock, in the hall of the Medical Library Association. Reader, Dr. C. M. Jones. Subject, German Measles. M. H. RICHARDSON, M. D., Secretary.

Deaths reported 3110 (no report from New Orleans): 1403 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 1065, diarrhoeal diseases 436, consumption 371, diphtheria and croup 208, lung diseases 182, typhoid fever 154, malarial fevers 80, small-pox 53, scarlet fever 53, whooping-cough 32, cerebro-spinal meningitis 21, puerperal fever 14, erysipelas eight, measles six. From *malarial fevers*, New York 21, Brooklyn 12, St. Louis 11, District of Columbia nine, Baltimore seven, Chicago and Charleston five, New Haven three, Buffalo and Nashville two, Philadelphia, Cincinnati, and Holyoke one. From *small-pox*, Chicago 26, Pittsburgh 12, Philadelphia 11, New York three, District of Columbia one. From *scarlet fever*, New York 24, Brooklyn 11, Philadelphia seven, Pittsburgh three, Chicago two, Boston, St. Louis, Baltimore, Buffalo, Lowell, and Worcester one. From *whooping-cough*, New York 14, Chicago five, Philadelphia, Brooklyn, and Boston three, Baltimore, Providence, Lynn, and Malden one. From *cerebro-spinal meningitis*, New York five, Chicago and Cincinnati three, Worcester and Fall River two, Philadelphia, Boston, Baltimore, Buffalo, Chelsea, and Clinton one. From *puerperal fever*, Chicago four, Brooklyn, Boston, and St. Louis two, Philadelphia, Buffalo, New Haven, and Lowell one. From *erysipelas*, New York three, Philadelphia, Chicago, St. Louis, Buffalo, and Holyoke one. From *measles*, New York and Chicago two, Brooklyn and Buffalo one.

Four cases of small-pox were reported in St. Louis, five in Cincinnati, one in District of Columbia, 76 in Pittsburgh, and one in Milwaukee; diphtheria 18, scarlet fever seven in Boston; diphtheria eight, scarlet fever five, in Milwaukee. Dysentery 21, erysipelas in Buffalo.

In 40 cities and towns of Massachusetts, with a population of 1,046,394 (population of the State 1,783,086), the total death-rate for the week was 21.98 against 22.99 and 21.03 for the previous two weeks.

For the week ending September 10th in 149 German cities and towns, with estimated populations of 7,740,071, the death-rate was 23.8. Deaths reported 3537; under five 1891; pulmonary consumption 414, diarrhoeal diseases 281, acute diseases of the respiratory organs 175, diphtheria and croup 132, scarlet fever 97, typhoid fever 73, whooping-cough 59, puerperal fever 14, measles and *rötheln* 10, typhus fever (Thorn) one. The death-rates ranged from 12 in Altona to 45.1 in Posen; Königsberg 25.1; Breslau 30; Munich 36.6; Dresden 26.4; Berlin 21.4; Leipzig 18.8; Hamburg 22; Hanover 16.1; Bremen 16.4; Cologne 24.1; Frankfurt 17.9; Strasburg 18.2.

For the week ending September 17th in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 17.3. Deaths reported 2521; scarlet fever 135, diarrhoea 119, fever 57, whooping-cough 48, measles 33, small-pox (London 26) 27, diphtheria 16. The death-rates ranged from 12.1 in Oldham to 30.6 in Hull; Leeds 13.8; Bristol 14.9; London 15.7; Birmingham 16.1; Sheffield 16.4; Manchester 16.7; Liverpool 28.2; Edinburgh 15.9; Glasgow —; Dublin 21.9.

For the week ending September 17th in the 21 chief towns of Switzerland, population 479,934, there were 33 deaths from diarrhoeal diseases; typhoid fever six, diphtheria and croup five, whooping-cough four, acute diseases of the respiratory organs three, puerperal fever and small-pox one each. The death-rates were, Geneva 22.8; Zurich —; Basle 27.6; Berne 28.1.

SOME OF THE CAUSES OF INFANTILE ECZEMA, AND THE IMPORTANCE OF MECHANICAL RESTRAINT IN ITS TREATMENT.¹

BY JAMES C. WHITE, M. D.,
Professor of Dermatology in Harvard University.

THERE is no affection of the skin so frequent in infancy, nor any in the whole range of children's diseases more difficult to manage successfully than eczema. That tissues so delicate and complex as the integument of the new-born babe should find the conditions of extra-uterine existence more varied and exciting than the equable protection afforded by its long amniotic bath is self-evident, the only wonder being that it withstands so well the rude abuses of its early management. Let us briefly consider what these are: First, from its prolonged, placid, subaqueous life it emerges into sudden contact with the more stimulating properties of an entirely different element, the atmospheric ether. For the first time its capillaries dilate to their fullest extent under the new conditions of respiration, an independent and intensified circulation, and spasmodic vocalization. So, too, its glandular systems are called upon to adapt themselves to the strange external surroundings; the sebaceous follicles to modify the character of their secretion, the sweat glands to perform their functions probably for the first time. Then its abrupt acquaintance with the foreign materials of the outer world. Anointed at once with fats, too often a rancid vegetable oil; then rubbed with a chemical compound, more frequently than otherwise composed of impure constituents, and so imperfectly combined that an excess of alkali is at liberty to exercise its caustic action upon the susceptible skin; then plunged into water of all varying temperature, and briskly rubbed; and finally received upon a rough blanket and dried by friction, it may be, with a coarse towel. Such is often the first treatment the skin receives. Later the dressing: around its abdomen is bound tightly a broad flannel band, between its legs are stuffed thick folds of napkin, and about its lower extremities again the rough contact with the woolen petticoat, all ingeniously adapted to irritate the skin by overheating, pressure, and rude friction.

Is it at all unreasonable that in this its first hour's experience of the new life the skin should find cause to express resentment, or should fail to adapt itself immediately to such strange surroundings, and present within the first day or two a fugitive congestion of greater or less extent, a mild follicular inflammation, or other abnormal phenomena, which may readily develop into a more serious and permanent disturbance? But to these are soon added other exciting conditions arising from mistaken opinions as to the care of the baby's skin, or from neglect of its person. The discharges are too often allowed to remain too long unremoved. That irritating fecal matter and great folds of napkin saturated with urine left by the hour in contact with the tenderest parts of the skin should produce the condition called intertrigo is what is to be expected. Such neglect is a very frequent exciting cause of eczema among the poorer classes, who cannot give the requisite attention in this respect to their babies. So,

too, the frequent regurgitation of milk curdled by the gastric acid, and allowed to saturate the clothing around the neck throughout the day or night, gives rise to a similar inflammatory condition between the heavy folds of skin in this position in fat infants. Imperfect removal of the thick coating of smegma at the first washing, or of the superabundant secretion which sometimes continues for a few days after birth, from between the folds of the skin, is the cause sometimes, also, of the same inflammation in the groins, navel, and around the neck.

Mismanagement of this secretion in another position forms one of the most frequent causes of infantile eczema. It is not an easy matter to remove from the scalp this prenatal cap of cheesy material without first thoroughly mixing it with other fat, the hair serving the purpose of fixing it all the more firmly to the skin. Very often, therefore, a remnant of it is left by the nurse, especially over the open fontanelle, which is added to by subsequent accumulation, as a timidity is generally felt in washing this apparently unprotected opening to the brain, while not infrequently the removal of this substance from the part is regarded with a superstitious feeling by the ignorant. Thus the sebaceous matter goes on accumulating until a thick coating is formed, sooner or later covering the whole top of the head, which retains the dust and dirt coming in contact with it, and assumes in time a brown or black color. It also retains the heat and moisture beneath it, which favor the decomposition of the newly-formed sebum, and thus produces a condition of active irritation. Not infrequently, too, attempts are made to remove this cap by violent means, as with the nails or a fine-toothed comb, which add greatly to the chances of dermatitis. After a time the scaly character of the covering is found to be undergoing a change into a crust. It cracks here and there, and allows the scalp to be seen for the first time, red and moist, and oozing through such openings a free escape of serum overflows the original sebaceous coating, and, coagulating, conceals it. The underlying redness extends beyond the crust to the bordering portions of healthy skin, and slowly or rapidly the case progresses to an acute eczema of the scalp, the milk crust and scald head of household nomenclature. Such is the history of development in a vast number of cases of the disease in this locality, from which seat it may spread to a more general distribution.

To these external agencies must be added the influence of extreme temperature as an important factor in the development of eczema in infancy. The baby is generally so well protected against the action of excessive cold that with the exception of a mild degree of "chapping," it rarely gives rise to any disturbance in the skin; it is the other extreme, excessive heat, which it cannot escape, which produces so much mischief in this direction. Under its influence the sweat glands are often stimulated into such hyperactivity that the cutaneous tissues immediately surrounding them become congested, presenting a punctiform redness, or the hyperæmia may become more generally diffused. This, the mildest grade of "heat rash," may disappear at this stage with proper care on the subsidence of the exciting cause. If, however, the infant be improperly clothed at such seasons, so that the excessive action of the glands is promoted, this congestion rapidly develops into a papular eczema, which may continue indefinitely. I have seen a hyperidrosis, induced by over-

¹ Read before the American Medical Association, May 4, 1881, and before the Boston Society for Medical Improvement, October 10, 1881.

covering during a single nap in summer, pass into an acute general eczema of several weeks' duration. To such imprudent management all children are exposed. It is chiefly, however, among the poorer classes that the evil results of over-heating and neglect of the skin in combination are found. Shut up by night in the stifling atmosphere of the tenement lodging, the skin has no opportunity to cool down after the baking heat of the day; the clothes, saturated with the irritating products of perspiration, act as continual warm fomentations upon the skin, which is rarely washed; these are the conditions which, kept up for weeks during the sweltering temperature of July and August, in our large cities, give rise to very characteristic changes in the cutaneous tissues of all grades of dermatitis. First, the punctiform congestion, perifollicular in seat; then the diffused erythema, both of possibly brief duration; then true eczematous inflammation, in its macular, papular, and vesicular forms, passing into the more advanced stages of oozing, crusting, and pustulation; later, furunculoid dermatitis, affecting large surfaces of the body, especially the head; and finally deeper-seated abscess formation, affecting the subcutaneous structures. Such cases of eczema in the miserable infancy of our crowded city populations during the prolonged "heated terms" form a large proportion of the cases which present themselves for treatment at children's dispensaries and the out-patient departments for skin diseases at such seasons.

Such are the more common causes of eczema in the early days of infancy operating upon the excessively tender skin from without, some of which continue to be actively operative throughout babyhood. These form, however, but a small proportion of all the cases of the disease which occur at this period of life, although by far the greater part of those concerning the aetiology of which we have any positive knowledge. During the past twelve years I have treated at the out-patient department for skin diseases of the Massachusetts General Hospital 5000 cases of eczema, of which 1890 occurred in children of ten years of age and under, as by accompanying table:—

Within the first year of life	569 cases.
Between 1 and 2 years of age	286 cases.
Between 2 and 3 years of age	280 cases.
Between 3 and 4 years of age	198 cases.
Between 4 and 5 years of age	144 cases.
Between 5 and 6 years of age	118 cases.
Between 6 and 7 years of age	93 cases.
Between 7 and 8 years of age	76 cases.
Between 8 and 9 years of age	66 cases.
Between 9 and 10 years of age	60 cases.
Total	1890

It will be seen how large a proportion of the cases occurred in the earliest years of infancy: 31 per cent. within the first year, 69 per cent. within the first three years.

The ratio of cases in children below the age of ten to the whole number of cases of the disease is 37.8 per cent.

Taking out the operation of the causes directly acting upon the skin from without, above mentioned, and a few other extraneous agencies, the parasitic chiefly, I do not hesitate to say that I know nothing whatever of the causes of the disease in the remainder. So far as my experience goes eczema, with the above exceptions, affects all classes of society alike; it occurs at all seasons of the year; it comes in children of all degrees of

health, in the perfectly sound as frequently as in the feeble; it has no necessary connection with any other disease of childhood, even of coincidence, except fortuitous; it comes during dentition only because dentition is synchronous with infancy, although it may sometimes be temporarily aggravated by its active disturbing influences; it shows itself in an equal proportion among bottle babies and those reared by the breast, and is as independent of the nature of diet in the later years of childhood; and if there be other assigned causes for its production, of which in fact there is no end, I may here say that my observation gives me no justification for believing any of them. If a child have an inflammatory process affecting the internal skin anywhere, or the tissues of the lungs, kidneys, liver, brain, or any other structure of its system, it is not considered necessary either for the physician in attendance or the writer on such disease to account for its being, nor to offer, as a satisfactory cause of its existence, a supposed sympathy with or dependence upon the state of the blood, or the condition of some other organ or function, or to invent a hundred other imaginary aetiological relations which cannot be refuted because they rest upon no logical data. We know no more of the aetiology of infantile eczema to-day than of that of the majority of other affections of infancy. Let us then use the same honest and reasonable language in discussing it.

In infancy the disease almost always presents itself primarily in the acute forms *E. erythematousum*, *papulosum*, which under the constant rubbing and scratching to which the skin is subject, readily become excoriated and develop into *E. madidans*, and less frequently *E. vesiculosum* or *pustulosum*. In process of involution these naturally pass through the crusted and scaly stages of the affection also. A certain degree of infiltration accompanies the most acute forms after a short duration, which in obstinate cases amounts to a considerable degree of thickening of the corium. Upon the face and scalp it almost always tends to assume its most inflammatory type, serum oozing copiously from the denuded skin and drying, when left long enough unmolested, into thick yellow crusts frequently mixed with blood from the deep excoriations made by the nails, or with pus and sebum upon the scalp. Upon the rest of the body the papular variety is the most common.

All these forms are accompanied by an intense itching which demands relief by scratching, but which only adds to the sufferings of the little patient by aggravating the harassed state of the cutaneous sensitive nerves. This desire, almost always incessant, becomes in many cases a real paroxysmal frenzy, the hands and feet being used simultaneously in scratching, while the head is violently and rapidly rubbed from side to side against the pillow, the clothing, its own body, the attendant, or any opposing surface which offers. This is repeated at shorter or longer intervals throughout the day and night. Under such persistent violence the inflammation of the affected portions of the skin is of course intensified, the hyperæmia is perpetually sustained, the protecting crusts and newly-formed cuticle are constantly torn away, and the tender cells of the rete and the papillary layer are plowed into unmercifully. After such furious attacks the whole head, or large areas of the general surface, looked as if just flayed, intensely red, dripping with serum, and presenting numerous points or long furrows of free hemorrhage. But the effects of this violence are not confined to the parts principally affected; the neighboring portions of skin are unavoidably

abused also, with the necessary result of a development of the disease in such directions, and its more or less rapid spread over large extents of surface. It is in this way that a local eczema, confined at first, as in the great majority of cases it is, to the scalp or other part of the head, becomes general, the disease assuming its most advanced or active type in the most robust children, for it is these who rub and scratch most vigorously and endure the longest. Indeed, it is a marvel how long and well an infant a few months old will bear such strains upon its delicate nervous system, as these paroxysms of frenzy must be. Adults describe those of much milder form attendant upon various kinds of cutaneous pruritus as resembling in their immediate exhaustive after-effects those following the sexual orgasm. The want of continuous sleep, too, should have its ill results, but strange to say, such a child may lay waste the strength and health of a household by the care it demands through months and months of nights and days, and remain at last its only healthy representative in all respects save its skin, retaining its nutrition, plumpness, vigor throughout. The health of those in charge of it becomes, in fact, eventually the chief object in view in the cure of the baby.

This is in no way an exaggerated picture of the disease; every physician recognizes the type and his inability in many cases to deal with it. Is it strange that such cases should be obstinate under ordinary treatment, and resist change after change in method, improving to a slight extent for a few days, it may be, to relapse as often? Is it surprising that such patients should be transferred from one physician to another and another until the fortunate last one of all is reached? It is strange, however, that there should be found many a physician advising parents that it is either useless to do anything for the cure of the disease or dangerous to attempt it. The writer has seen numerous cases of severest eczema in infants allowed to continue for months and months without local treatment under the advice of fashionable homeopathic practitioners, to the effect in one instance that an application even of oxide-of-zinc ointment would be sure to bring on convulsions and death. Such let-alone treatment is at least possibly consistent with some sectarian tenet and therefore pardonable; but what can be said in the more numerous cases where the so-called regular family physician pursues the same inhuman course and permits a child to suffer the torments of self-torture, and the health and happiness of a family to be destroyed through long periods of distressful days and endless nights in at least apparent subservience to the groundless popular fear that it is dangerous to cure or "drive in" an eruption? In too many such cases the plea of ignorance cannot certainly be offered in his justification. Every physician may, indeed, often have to say that he has tried this and that remedy advised by authority without result, and that finally he has let alone what apparently could not be controlled by treatment; such want of success forms too nearly the rule rather than the exception in infantile eczema.

It is, therefore, to present the claim of a method which offers a surer success in the treatment of so obstinate an affection that I venture to ask your attention. The method to be proposed has no element of novelty in it, introduces no new or specific drug to the overburdened materia medica of the disease; it is only a system of proper restraint which shall give the therapeutics of eczema in infants the same chances of success as in other

periods of life. For so long as any degree of eczematous inflammation of the skin exists this subjective symptom, itching, is necessarily present, and is as much a part of the disease as the hyperæmia or any of its manifold forms of surface lesions. So long as there is any itching, so long will the child rub and scratch, and so long will all direct treatment in the form of washes, powders, ointments and the like, or any form of internal medication, be of little or no avail, for a minute of unguarded scratching will more than undo all that has been gained by their use in twenty-four hours. They must be allowed to do their proper work, and this can only be made possible by making this counter-agent impotent. This cannot be accomplished by any number of nurses or attendants of the most conscientious vigilance, for two persons would have to hold the child simultaneously during every moment, day and night, to insure safety, and this is wholly impracticable. It can only be effected by a properly constructed harness or system of clothing adapted to the extent and position of the disease in every case.

Let us consider, first, its application to the most common condition, acute eczema of the head. A skull cap is to be made of firm old cotton or linen cloth so as to closely fit the calvarium; a mask of the same material is then shaped to the face, with exactly placed apertures for the eyes, nose, and mouth, and with slits for the ears. It is to be gathered in somewhat beneath the chin, and made long enough to lap some two inches at the back of the head. This in mild cases will prove to be a sufficient protection against the efforts of the infant to get at the irritated skin with its hands, and a shield against the damage inflicted by rubbing the inflamed parts against every opposing surface which offers. It is sometimes sufficient that such a mask and cap should be worn only while the child is sleeping, the only time when it is generally left unwatched, but such partial use is permissible only in the mildest grades of the disease. But the protection from without afforded by the mask is only one of its important duties; it may also be made to take a valuable part in the direct treatment of the disease. Of course its use will never interfere with the application of any other class of remedies to the skin, but it may be smeared with ointment, and, adjusted tightly, form an impermeable coating to the inflamed skin. It may be worn in this way for twenty-four hours without change, or removed at shorter intervals for the application of such other remedies as the case demands. The nose and ears should protrude through their appropriate openings to assist in retaining the mask in position, which should be tightly stitched or pinned with fine safety-pins at the back of the head. But generally additional means must be employed against mischief, as the hands of a strong infant are capable of doing injury both to the mask and the skin beneath during the paroxysms of itching, or of developing the disease upon the neck and other parts. It is generally best, therefore, in all but the mildest cases of the affection, even when confined to the head, to use a sort of strait-jacket in addition to the mask. A hole is to be cut in the closed end of a small pillow-case large enough to allow the child's head to pass through. This is to be drawn down over the body and arms. The back and front surfaces are then to be stitched together between the arms and body by a long darning-needle from the axilla down to the ends of the

fingers, thus confining the arms in closed sleeves to the sides. The same result may perhaps be more readily accomplished by the use of several safety-pins in place of the stitches, by which the jacket may be more readily taken off when necessary. The pillow-case is then to be fastened together by the pins between the legs from front to back, so that the arms cannot possibly be brought up to the head. This lower fastening can of course be removed without trouble as often as it is necessary to change the napkin. We have thus rendered the hands completely harmless. The mask and jacket are of course resisted by the little patient at first, but in a day or two are worn, when adjusted, without a struggle. The chief opposition to their use come always from the mother, to whose pride in her child's appearance they are often a sore affront. The jacket should be worn day and night, and while removed for the application of other dressings, or during the bath, the hands are not for a moment to be left unheld by an additional attendant. It is astonishing what results are often accomplished within twenty-four or forty-eight hours by the mask and jacket. The skin, having for the first time, it may be for months, a chance given it of expressing its desire or capability of improvement, loses rapidly its inflamed condition, and its nerve filaments, free from the constant insults they had received, quiet down and in turn give the patient the rest so long wanting. The demoralization of the household disappears with the same rapidity, and in a week, it may be, the disease is seen to be well on the road to recovery. Such is by no means an uncommon result. But not until the skin is completely restored to its normal condition, or at least until all signs of the inflammatory state and of pruritus have disappeared, are these mechanical means of restraint to be relaxed.

When, however, the disease is more extensively distributed, covering the arms and legs, or the whole surface as well as the head, the necessity of their employment is the more imperative, as the suffering is greatly intensified and the temptation to injure the skin increased in proportion to the greater area affected. In such cases it often becomes necessary to confine the feet and legs as well as the upper extremities, to prevent their constant friction against each other. The same method of pinning through the pillow-case from front to back should be employed, following the inner line of the legs from the crotch to the feet, while they are kept some distance apart. If the outer edge of such trousers be then fastened to the bed or cushion on which the child is seated, the legs can neither be drawn up or approximated to any dangerous contiguity. To any who think that such restraint, preventing as it does almost wholly the natural movements of the limbs, might be not only uncomfortable but injurious, the custom of many nations of tightly swathing their infants through the early periods of life without harm may be cited.

But with these preventive measures can we combine means also of hastening more directly the cure of the affection? It is not my intention to discuss here that important and difficult subject, the general therapeutics of infantile eczema; I will state how far only the former may be made to do additional service in the latter direction. As I have stated that the cap and mask may be smeared with ointments, so may the arms and legs be covered with bandages anointed with the same before being placed in confinement. A favor-

ite plan of managing this part of the treatment with myself is as follows: To the head and face or other parts affected there may be applied, morning and evening such washes as are thought advisable. The cap and mask, previously well smeared with some ointment, are then carefully adjusted, pressed firmly into the skin, and tightly fastened. Other parts are then similarly treated, the ointment being applied to the body and limbs if required, on thin old cotton or linen cloths. The pillow-case is then put on carefully and pinned into form. These dressings are left unchanged twelve or twenty-four hours, according to circumstances, and are then removed for a short time for the application of other needful remedies. The same cap and mask and other swathes are then to be respread and applied as before. In this way one set of cloths may be made to serve for three or four days, according to the amount of discharge from the skin. If they be changed daily the ointment is mainly wasted in saturating the texture of the cloth, leaving little free to act upon the skin. Of course in some cases ointments are not advisable, when the mask should be worn dry.

Such are the simple mechanical means, to be found in every household, which I regard as all-important in the treatment of one of the most distressing and rebellious diseases of infancy.

A PECULIAR CONDITION OF THE CERVIX UTERI WHICH IS FOUND IN CERTAIN CASES OF DYSTOCIA.¹

BY ALFRED HOSMER, M. D.

THAT extraordinary form of dystocia to which attention was directed in former communications² still retains much of the character of an interesting novelty; its importance, which is not unlikely to be underrated for the very reason that its occurrence is supposed to be rare, is not as yet generally appreciated. No allusion is made to it in the last edition of Leishman's Midwifery, published scarcely a twelvemonth since, and revised by the hand of the author. Nor is it mentioned in the second English edition of Playfair's Midwifery. Under date of June 18, 1878, Dr. Playfair writes to me as follows: "I have never seen, or at least recognized, a case of the kind; but I can quite understand the occurrence." However, in the second American edition of this writer's work, Dr. Harris has introduced the subject under the head of "tetanoid falciform constriction of the uterus."³ In many respects this designation is suggestive and significant, yet it lacks precision, intended as it is to provide for a certain mental reservation with which a topic new to text-books is discussed by the editor, who, at the time of writing, has not been convinced that the internal os is the seat of the anomalous constriction. The title under which we first introduced this subject had its origin in some early impressions which were received in connection with the imperfect investigation of a single case. I was not ready to abandon it until

¹ Read at the meeting of the Obstetrical Society of Boston, February 12, 1881.

² For the sake of uniformity the original title is still used, though the condition under consideration would more properly be designated as *tetanic spasm of the internal os*.

³ *JOB. LANCET*, vol. XXVIII., No. 12, p. 360, and No. 22, p. 683.

⁴ Playfair's System of Midwifery, second American Edition, page 350.

the testimony of clinical observation and anatomical study should have proved what relation exists between a preternatural elongation of the cervix and that strange tetanic contraction limited to a narrow segment of circular fibres of the uterine muscle; and to what extent the amount of this elongation would indicate the degree of dystocia to be encountered, and measure the danger to which the patient is to be exposed.

In the third American edition of his book Dr. Playfair respectfully admits the existence of this odd deformity of the uterus, and says: "I have no personal experience of this complication, which, fortunately, must be very rare." He does not attempt to treat or discuss a subject a knowledge of which he would be forced to derive mainly from sources which are neither indorsed by personal acquaintance nor certified by high professional reputation. Yet English writers, whose books teach classes of the largest possible size, must soon appreciate a new form and phase of difficult labor, and make it a visible, if not conspicuous, object in the obstetric field; otherwise their instructions in midwifery will be incomplete, and fail to provide for one of the most serious emergencies of practice.

It is not to be supposed that this Society will demand any additional proof of the possible existence of an *ante-partum* hour-glass contraction of the uterus. But there is a great diversity in cases which, for convenience and simplicity of classification, are designated by the same name, and the symptoms found in a single instance can rarely, if ever, suffice for a complete description of any morbid condition. I have therefore thought proper to place before you all the clinical material not included in my original collection which I have been able to obtain from the periodical literature of medicine. The several cases will be presented, as far as possible, in the chronological order of their occurrence.

In the *Medical and Surgical Reporter* of February 5, 1876, may be found the report of a case of hour-glass contraction. The patient was a married primipara aged thirty-one. Labor began in the afternoon of April 17, 1874,¹ upon what was, by calculation, the one hundred and sixtieth day of pregnancy. At the end of sixty hours a dead child was delivered, and without assistance, so far as the record enables us to judge. The womb not diminishing in size, its cavity was explored for the purpose of ascertaining if it contained another child. "The placenta was found attached at the fundus² of the uterus, and it was still quite impossible to make out the kind or condition of the body above." Twenty hours later a consultation was held, and upon removing a placenta there was found an hour-glass contraction, the degree of which was such that there was left an opening of only one inch in diameter, through which a second fetus could be felt. It was a slow process by which the operator reached and brought down a foot. Progress was slow, and only made by dint of persistent traction, and continued so until the constriction came to encircle the fetal neck. At this point all movement "seemed to be entirely arrested, when, as if something was giving way, the child made rapid advances by the woman's natural efforts, and was born headless." There were two separate placentas, both of which were duly expelled. "No flowing followed: patient slept some

from exhaustion, and with but little tympanites." "On the morning of April 22d the head was found, brought nearly down by the organ's own power." The amount of hemorrhage was not dangerous, yet the woman died on the afternoon of the eighth day, April 24th. This case occurred in the practice of Dr. M. D. Good-year, of Gorton, N. Y. It is to be regretted that his report is not made with more of fullness and detail. Such as it is, I offer it without comment.

In the *Pacific Medical and Surgical Journal*, January, 1879, Dr. W. A. Briggs, of Sacramento, Cal., relates the following facts: A married woman, aged thirty-one, whose four previous pregnancies had terminated normally, fell in labor, at term, August 3, 1876. A few hours later the right arm of the fetus was found to be protruding through the os. At six A. M. on the 6th Dr. B. was called in consultation. He found the patient in active labor, with no untoward symptoms and with "pelvic dimensions normal." He proceeded to turn, but upon the first search was unable to find the feet, which, together with the head, proved to be beyond easy reach, inclosed as they were in the superior uterine chamber. During a second attempt the hand came in contact with what was taken to be the fundus of the uterus, and very soon the cessation of a pain allowed the finger to pass beside the fetal neck "through an opening in the presumed uterine roof," and for an instant the alarming impression was conveyed that the peritoneal cavity had been entered. It is soon discovered that the edge of the supposed aperture is perfectly smooth, and to the touch suggests "that a silken cord has been run beneath the mucous membrane of the womb, and tightened about the child." During a pain "the 'cord' becomes more rigid, grasps the neck of the child with my finger and almost cuts them. Such are its wonderful power and tenacity." At the instant of uterine contraction the constriction embraced the fetus with such firmness that there seemed to be not simply contact but continuity of tissues belonging to different individuals, so that all trace of an opening disappeared. The patient was now etherized. At first the constriction was found to be as firm as ever, and the child was "held as by a vice." Force was required, yet by digital and manual dilatation the stricture was gradually overcome, and at the end of thirty minutes the hand was fairly within "the upper cavity." The passage of the fetal head having been provided for by securing a still farther relaxation of the annular contraction, the feet were seized and brought down, and delivery was accomplished without difficulty. The child was dead. The placenta followed naturally. The patient made a slow but complete recovery. To the report of this case the writer appends some thoughtful remarks, interesting to read, but not sufficiently brief for introduction here. He insists upon that difference of anatomical structure which makes the contrast between the uterine body and the cervix, and clearly points out the relations in which these two portions of the organ respectively stand to the parturient function. He states at length, and illustrates by diagram, his theory of the manner in which the innate forces of the womb lose their natural equilibrium, and thus produce deformity and dystocia.

In the *North Carolina Medical Journal*, March, 1878, A. H. Goelet, M. D., of New York, furnishes a very meagre and unsatisfactory account of a case of *ante-partum* hour-glass contraction, which came to his notice July 24, 1877. The patient was a married woman,

¹ My first and only observation was made in September, 1876.

² This statement may fairly be questioned. Those portions of the report which refer to the placenta are somewhat confused.

and this, her third labor, was premature, occurring in the middle of the seventh month. In due time "the uterus was discovered to be contracted in the centre, the fetus above the constriction and a finger projecting through." On account of a hemorrhage, which in amount was sufficient to compromise the safety of the woman, it was decided to deliver at once. "With great difficulty one finger was forced through the constriction, then another, and after considerable search a foot was found." The constriction opposed the passage successively of the breech, the shoulders, and the head, so that at each of these points there came a requisition for "all the force that could be exerted with both hands." The removal of the placenta was effected with considerable difficulty. Beyond this point the record does not go. But if the foregoing report is based upon observation that is accurate and authentic, the case is one of unusual interest and significance. For it would prove that the development of an ante-partum hour-glass contraction does not necessarily depend upon those influences which may be traced to the relations existing between either the maternal pelvis or the uterine cervix and some portion of the fetus.

Among the papers announced to be read before the Gynecological section of the American Medical Association, at the meeting held in Buffalo, in June, 1878, was one entitled "Hour-glass Contraction of the Uterus prior to the Expulsion of the Child, by T. A. Reamy, M. D., of Cincinnati, Ohio." What I take to be this paper is reprinted under date of May 10, 1879, in the *Cincinnati Lancet and Clinic*. It contains the report of three cases, one of them being referred to the *London Medical Gazette*, July, 1848, from *Schmidt's Jahrbücher*, vol. lxiv., p. 37, 1849. A foot-note alludes to a fourth case, "recently reported in the *American Journal of Medical Sciences*." The paper contains some facts that are extremely interesting. It proves that the patient in whom this formidable complication occurs for the first time is not necessarily a primipara, but that it may present itself in a woman who has passed through as many as seven normal labors. It also shows how the abdominal wall may be moulded to the shape of the deformed uterus, and how readily external palpation may often recognize the constriction. As the result of careful clinical observation, it certifies to the marked differences in the physiological condition and action of the two portions of the uterus which are respectively above and below the stricture. The supposed obliquity of the constriction in one instance, raises the question of the possibility of an unequal elongation of the opposite sides of the cervical cylinder. Case II. of this series forms a very valuable acquisition to the history of this subject, illustrating, as it does, the relation which may exist between tonic spasm of the internal os and the several stages of a multiple birth. According to the record, as the result of an eighth pregnancy, two living male children were born by a brief and easy process. They weighed, the first five and one half, the second five pounds. The uterus was found to contain a third child, and through the abdomen it was "easy to trace the rigid hour-glass contraction." "By persistent traction the hips passed through the constriction, and a dead female child of four and three quarter pounds was delivered." "Just below the umbilicus, at a point seized by the constriction, the body of the child was nearly cut in two." The placenta, with three cords adhering above the constriction, was reached and removed with the greatest diffi-

culty, and only by the successive efforts of three physicians, each of whom experienced in a painful degree the paralyzing and disabling effect of the severe pressure to which the hand was subjected in its vigorous and forcible efforts to overcome the occlusion, and obtain possession of the true uterine cavity. The woman speedily died.

The *Boston Medical and Surgical Journal*, in its issue of May 27, 1880, published the proceedings of the Society, at the regular meeting held in October, 1879. Therein is included the report of a case made by Dr. L. R. Stone, in which a firm constriction, encircling the fetal neck, seriously retarded the progress of labor, rendered instrumental interference necessary, and in some way determined a still birth. The mother recovered. It is worthy of note that a degree of relaxation in the stricture seemed to be produced by the use of ether.

On page 397 of the *British Obstetrical Journal*, September, 1879, may be found "Note of a case of spasmodic contraction of the lower uterine segment during the first stage of labor." It was under this title that Dr. Angus MacDonald made a communication to the Obstetrical Society of Edinburgh, at a meeting held February 12, 1879.¹ Mrs. C., a chronic epileptic, then advanced ten or twelve hours in her fifth labor, was visited in consultation by Dr. MacDonald at 9.30 p. m., December 16, 1875. Pains were severe. "Immediately above the cervical segment, which was half dilated and easily dilatable, the lower uterine segment was felt to project or bulge in a peculiarly rigid or shelving manner," and to be as "hard as a deal board." Such was the rigidity of the parts that the presentation could not be ascertained. "The perineal and levator ani muscles, as well as the lower uterine segment, were observed to be thrown into a condition of intense spasms by every attempt to perform a vaginal examination." The full impression of chloroform removed the spasm at once, and through the unbroken membranes a small head was found to be presenting at the time. During each pain the external os and cervical canal remained flaccid, but the inner os was closely shut, and the head, instead of being depressed by uterine action, was elevated very distinctly. In due time the need of artificial aid was obvious, and with the assistance of chloroform anesthesia, version was performed with ease, and the child was saved. "The placenta was expelled spontaneously about fifteen minutes after the birth of the child." The record contains no intimation that the maternal convalescence was not a rapid and prosperous one. The reporter alludes to a possible complication of version, which is sometimes fatal to the child, and which consists "of the trouble that is occasionally experienced in getting the after-coming head through the spasmodically contracted lower uterine segment."

The species of case which gives title to his communication, is in his experience unique. The conclusion must then be that it is only in an extremely mild and manageable form that he has witnessed ante-partum hour-glass contraction.

With one exception, the ideas which found expression in the discussion that followed were based upon the theory which located the spasm in the internal os and adjacent muscular tissue of the uterine body, and acquitted the cervix of all participation in the abnor-

¹ The Obstetrical Society of Boston had discussed this subject as early as February 9, 1878.

mal and perverted condition. The "why" of this thing did not escape attention, and the question receives a provisional answer, as follows: "It would, therefore, appear to me that the predisposing cause in this case was a neurosis affecting the vagina and the lower part of the uterine body, but not extending to the upper ranges of the body, or to the fundus uteri, and which seemed to act in such a manner, on slight stimulus, as to throw the parts within its reach into a condition of spasmodic contraction. The pressure of the head against the internal os during a pain would appear of itself to have been sufficient to start this spasmodic condition, or, in other words, to have probably acted as the proximate cause of the spasmodic condition." Science may gain something if future observers will bear in mind the hint here given as to the relation existing between individual temperament and tonic contraction of the internal os. In my first paper I distinctly stated the possible aggravation of such contraction through the reflex action of measures that were intended to be remedial.

In view of the terms of the title under which I now for the third time ask the attention of the Society to a dangerous and anomalous condition, which in November, 1876, was introduced under the name of ante-partum hour-glass contraction, I desire to quote Dr. J. Matthews Duncan. His article On Two Contrasted Forms of Weak Labor, copied from the *Obstetrical Journal*, February, 1878, page 705, may be found in Braithwaite's *Retrospect*, Part 67, July, 1878, page 184. In one case labor is weak because the uterus of the elderly multipara is feeble and inert, endowed with only a small remainder of its original energy, and incapable of vigorous and efficient action. In the other case, the subject is generally a primipara, or a young woman having a special nervous mobility. The labor is practically weak, not through any deficiency in the inherent muscular power of the womb, but for the reason that the contractile force of the organ, instead of undergoing the normal conversion into the propulsion and expulsion of the child, is expended in the production of deformity. In other words, the body of the womb acquires a permanent retraction; with each succeeding pain becomes a little shorter in its longitudinal dimension, always adding something to the thickness and strength of its wall; while the cervix is elongated and attenuated in a corresponding degree; the fetus becomes stationary, and the condition of labor loses its parturient character. The disproportion between the two portions of the womb may be so great that the lower margin of the uterine body is sometimes raised almost to the level of the umbilicus. In both these forms of weak labor, "the child is brought into the world by a very small expenditure of force." Dr. Duncan cites the case of an "excessively nervous" woman whose three labors were all, in a similar way, busy and painful, but tedious. "When the head reached the perinæum, while the pains continued severe, progress was arrested." It was only at the third confinement that the nature of the case was exactly ascertained. At that time "delivery by forceps was effected without any effort worthy the name of pulling; the child was little more than lifted out of the passages."

Without forgetting the allowance that is due to irregularity in pelvic size or shape, let us make a comparison, placing upon one side that case in which the uterus, by the retraction of its body and the elongation of its neck, loses the relation and proportion that nat-

urally exist between the two portions which in their combination constitute the organ; and in which, although spontaneous delivery is extremely improbable, the removal of the child is effected by artificial means with surprising facility, and with absolute safety. Upon the other side, we will place the case in which uterine deformity of the most aggravated kind is produced by the introduction of a third element; by the addition of a tetanic spasm of the whole circle of the internal os to the retracted body and elongated cervix, and in which not only is spontaneous delivery simply impossible, but the termination of labor is reached with a difficulty that is beyond all description, and can be appreciated by those alone who have met and overcome it, and have been eye-witnesses of the appalling danger to which it exposes both the lives that are involved in every case of child-birth, and which natural labor was never intended to put in jeopardy.

Trite and old is the saying that new things are not to be found on this side of the sun. Possibly the older obstetricians failed to appreciate all that passed before their eyes, or came in contact with their hands, just as the old physicians accepted identity when there existed a similarity only the most remote, and in diagnosis overlooked distinctions which now irresistibly force themselves upon the attention. But within seven years, that is, since April, 1874, by a coincidence that is not without precedent in the history of even important discoveries, ante-partum hour-glass contraction has been observed in so large a number of cases as to modify the impression of extreme rarity and extraordinary character which was conveyed by the first report of a case made to this Society. The wide geographical distribution of the instances here collected proves that this particular complication of labor does not take its origin in accident or influence of place, but that it forms a legitimate and indisputable part of universal midwifery, and is entitled to a high rank among those difficulties and obstacles to delivery which make the process of child-bearing in any degree unnatural. Different observers, in entire ignorance and independence of each other, have made their several descriptions in words and phrases so nearly identical that there can be no doubt that they have all been dealing with the same thing.

I will not attempt a careful analysis of the several cases which constitute the substance of this communication, but upon making a general review of them, I would draw the following conclusions, and ask their provisional acceptance:—

(1.) Simple elongation of the cervix, even though it be excessive, disables the uterus by perversion of its force, renders spontaneous expulsion improbable, but in connection with artificial delivery does not produce a condition of things to which the term dystocia can be applied with any propriety or significance.

(2.) Tonic spasm of the internal os may in single labor be developed so early as to imprison the whole fetus in the cavity of the uterine body, and in a multiple labor its production may be so postponed as to interfere only with the birth of the last child. Its existence cannot necessarily be referred either to pelvic deformity, to extreme elongation of the cervix, nor to the occupation of the cervical cavity by any portion of the unborn child.

Finally I would call attention to the facts that tonic spasm of the internal os has shown a marked tendency to recur in the successive labors of those who have

once or even twice survived the danger to which it exposed them, and that the patient in whom it occurs for the first time is not necessarily a primipara.

The form of difficult labor to which this article refers, has sometimes been spoken of as "Bandl's dystocia." That obstetrician published in 1875 *Rupture of the Uterus*, and in 1876 *Relation of the Uterus and Cervix in Pregnancy and during Labor*. But I am not aware that in either publication he describes tonic spasm of the internal os. A competent medical friend, recently a student in Vienna, and thoroughly familiar with the German language, having searched at my request, writes under date of February 24, 1881: "I have looked carefully through the two pamphlets, and find no mention at all of a spasmodic contraction of the internal os."

REPORT ON PROGRESS IN THE PATHOLOGY OF DISEASES OF THE NERVOUS SYSTEM.

BY JAMES J. PUTNAM.

CONGESTION OF THE BRAIN.¹

THE diagnosis, congestion of the brain, familiar as it is, can hardly lay claim to more than a conventional significance. Its rights are, to be sure, upheld by various writers, among them so conservative and intelligent an investigator as Nothnagel,² but on the other hand there are many who believe that it holds its place partly because the term is so convenient as a pass-word, and partly because its very obscurity of meaning renders it difficult of criticism. Some authors have used it, with manifest impropriety, to connote a condition of cerebral exhaustion, where if it exists at all it is as a result, not a cause; others have made it stand for various groups of cerebral symptoms of which the origin was obscure, the onset and disappearance rapid and complete. The whole subject has received an able overhauling in the papers by Dr. Moxon, and in the clinical arguments which he adduces to show that the conception of congestion as a primary source of disease rests on no solid basis, but is a sort of remnant of a humoral pathology, we entirely sympathize with him. We do not regard ourselves as fully able to judge of the value of the strictly anatomical and physiological parts of Dr. Moxon's work. Some of his suggestions indeed tax the imagination too strongly to be accepted without caviling, while others appear to be of great value. He says: "I wish to show that no quantity of blood that can be forced into the vessels of a brain whose veins are not closed by obvi-ous pressure, does as a matter of fact cause any such symptoms (as those met with in the several serious and even fatal diseases, which are described under the name of 'congestion of the brain,' or 'determination of blood to the head'). I believe this may be proved beyond dispute. I should like to make clear that in doing this I am proceeding in harmony with the great principles enunciated by the illustrious Professor Virchow, who . . . proved that the life of texture is in the texture itself, its pathologized as well as its natural life, and that the movements of the blood in what is called irritation or inflammatory congestion are secondary to a demand which is made by the proper power of the texture elements. . . . And when I say that the forcing of blood into the vessels of

the brain produces no symptoms, I do not mean that no symptoms will attend a fullness of the vessels when that fullness has been caused by disturbance of the brain's texture itself. There will be symptoms, but symptoms caused in the texture by the very irritation that drew the blood to the brain, and not to be ascribed to the blood that is drawn thither."

Dr. Moxon then proceeds to analyze the anatomical, experimental, clinical, and pathological evidence bearing on this question.

The *experimental* testimony in favor of the theory of congestion of the brain as a primary disease is of the most meagre, and in fact there is none at all, with regard to *arterial* congestion, the only form which is of much importance to us here, since it is to this form that familiar groups of symptoms are ascribed. *Venous* congestion, due to complete or partial closure of the cervical veins, is a complex condition, calling for consideration by itself.

Moxon has now appealed to an unnoticed piece of evidence which he believes to be of the greatest significance as showing that arterial congestion is in fact innocuous.

It is, namely, evident that when the body is exposed to high pressures of air the movable fluids must collect to a greater or less degree in the practically closed cavities of the skull and spinal canal.

In the building of bridges by means of caissons as at St. Louis³ the workmen may be for hours under a pressure of upwards of three atmospheres, so that, according to Moxon's calculation, the blood must be driven into the cranial cavity with a force several times greater than the action of the heart, as measured by arterial tension, is able even under pathological conditions to exert. Yet these workmen, and even visitors to the works, so far from feeling any ill effects from this tremendous pressure are, if anything, especially buoyant and comfortable. It is well known that on their return to the outer air these same workmen are liable to suffer from a variety of serious symptoms, for which several causes have been suggested, but these need not concern us further here, since it is with the effects of increased not of diminished pressure that we have now to deal.

The sense of buoyancy felt under this high pressure is ascribed by Moxon to the abundant supply of oxygen carried by the increased current of blood to the cerebral tissues.

If Dr. Moxon's reasoning is really correct its great value must be evident to all. It is, however, difficult to believe that this is the case; and for the simple reason that since blood cannot enter the skull without displacing cerebro-spinal fluid, and since this fluid is, in the experiment, exposed to the same atmospheric pressure with the blood itself it would seem that the amount of blood in the skull must remain the same in the caissons as upon the earth's surface.

As to the experimental evidence with regard to *venous* congestion, it is well known that complete or nearly complete (if sudden) closure of the veins returning the blood from the skull is able to cause serious symptoms, which are essentially the same with those of cerebral anæmia, together with slowing of the pulse, from excitation of the vagus. The attempt is rarely made to differentiate between the action of carbonic-acid poisoning and of the excess of blood in itself as factors in their causation, yet this is plainly of the greatest importance if we wish to deal fairly with this subject.

¹ On the Pathology of the Cerebrum, in the Nervous System, from the Lectures of Walter Moxon, M. D., etc. Lancet, March 26, at p. 178.

² *Zentralblatt*, Oct. 2, 1880.

³ Report by Capt. Eades.

"These symptoms are not, however, what is habitually indicated by "congestion of the brain," and it is, furthermore, but rarely that an interference with the venous circulation sufficient to produce them is clinically met with. A considerable degree of interference of this kind is in fact of far less consequence than may be generally believed.

Thus Moxon says, in speaking of the effects of impeded respiration during violent paroxysms of coughing, as in pertussis or emphysema, the cause of venous obstruction most frequently referred to, "When a person is in a seizure of either of the forms of protracted cough which I have mentioned, the evidences of venous obstruction and imperfect aeration of the blood become apparent, often painfully so, and yet cerebral disturbances but rarely show themselves. Twice only have I known persons affected with old bronchitis, and habitually almost cyanosed, to stagger and fall in the extreme height of their paroxysms of cough. Every one must have seen the veins rise on the forehead, and a dusky color suffuse the face of persons coughing violently, when meantime nothing noticeable happened to the comfort of the brain. . . . Also, I believe, that general experience will be with me in recalling how, in examples of tumors in the cervical region pressing on the jugular veins, and even involving and completely closing one of them, the comfort of the brain is surprisingly little invaded. One of the most intelligent and clear-headed patients I have seen had the neck enlarged so that shortly below the chin it exceeded the girth of the head and face, and these were livid with venous obstruction, yet she denied to my questions every sign of cerebral annoyance."

Another striking instance of this sort may be adduced. Athletes at the circus, namely, often hang with the head downwards during a long series of evolutions involving many muscular efforts, both delicate and powerful, in the course of which the chest walls must often be fixed, and the glottis closed, yet they show no sign of distress.

It is worth mentioning in this connection that Mosso, after his long experience as an experimenter, has recently declared himself convinced "that the amount of blood circulating in the brain may be materially increased without causing any disturbance of consequence in the cerebral functions."¹ He further goes on to say: "So far as the circulatory disturbances arising from *venous stasis* are concerned every one would be prepared to admit that their effect upon the nutrition of the brain might be but slight. It is, however, a matter of much greater significance—in view of the accepted theories as to the aetiology of cerebral symptoms and their relation to the circulation—to learn that even a very considerable degree of *arterial hyperæmia* of the brain may occur without disturbing the cerebral functions in the slightest degree. This fact is well illustrated by the experiment with nitrite of amyl, recorded in a previous chapter, where we saw the cerebral circulation become materially more rapid, the volume of the brain increase, and the arteries dilate without the subject of the experiment feeling anything wrong other than a sense of warmth in the face."

Mosso believes that the effects on the nutritive changes in the cerebral tissues of increased *quantity* of blood, due, as in the above-mentioned experiment, to dilatation of the vessels, are different from those of

increased *tension* of the blood, causing a more rapid circulation, and thinks that the latter condition is induced when the cerebral functions are called upon for increased activity. It is difficult to see how this increased tension or pressure could occur clinically unless as a result of the action of a hypertrophied and rapidly contracting heart, not forced to expend all its energy in driving its contents through a very narrow opening.

A striking case of this kind is analyzed by Moxon. The aortic valves were incompetent, but the heart was greatly hypertrophied and beating with great violence, apparently from a defect in its inhibitory innervation. The temporal arteries were tense and bent, and each heart-beat made them spring sharply. "Yet," he says, "this man said that his head was quite free from unpleasant sensations, and when I induced him to cough and otherwise to use strong pressure of his expiratory muscles so that the veins rose in his neck, the heart meantime beating still more strongly and quickly with his exertions, no ill effects occurred in the way of morbid sensations in the brain."

These various statements as to the slightness of the effects of the congestion of the healthy brain with healthy blood become the more striking when it is remembered that the action of even very moderate *diminution* of the amount of blood makes itself at once evident, showing that the reaction of the brain to real disturbances of nutrition of circulatory origin is quick and delicate. In the absence of any more direct means of appreciating the quantity of blood circulating in the brain and the relation of a possible excess to such symptoms as may be present, one naturally turns, first to the physiological or experimental, then to the *pathological* tests. The former we have just considered, the latter will now occupy our attention.

In stating the post-mortem appearances believed to indicate congestion of the brain, we will follow Moxon, though it is a matter with regard to which text-book repeats text-book with extraordinary exactness. Four such appearances are usually described:—

- (1.) A swollen state of the brain.
- (2.) Distention, tortuosity, and varicosity of the veins and capillaries, and dark color of the gray matter.
- (3.) L'état criblé.
- (4.) Minute collections of blood or hamatoidine about the capillaries.

With regard to the first sign, Moxon says that in the large number of autopsies which he has made he has never seen anything that could be called swelling of the brain (as evidenced by flattening of the convolution-) except in case of increase of the intraventricular fluid or of apoplectic bleeding, as of tumor. In so far as the swelling is an indication of the distention of the blood-vessels it will be subject to the remarks upon this condition, which is the one next to be considered.

It is remarkable that all the best modern teachers on pathological anatomy, as well as most of the writers of text-books upon cerebral diseases, lay great stress upon the difficulty of judging from the amount of blood found in the vessels of the brain and its membranes after death the amount which had been present during life. It is admitted on all sides that a dependent position of the head and respiratory obstruction during the act of dying may congest the veins to almost any extent. Furthermore, as Moxon—quoting Mr. Hilton—points out, if the cranium be opened before the jugular veins are cut, a brain may appear saturated with blood which would otherwise have looked rela-

¹ Ueber den Kreislauf des Blutes im menschlichen Gehirn, 1881, p. 207.

tively pale. Moxon's remarks on these points, and his use of kindred facts concerning the apparent congestion of other organs, as the liver and stomach, are highly instructive, but we have room for only one quotation:—

"Can we infer from the amount of blood in the brain after death the amount during life?"

Perhaps one could not find a more decisive answer to this question than the answer given by Kussmaul and Tenner.

These observers were investigating the effects of ligature of the cervical vessels, and it was most important for their purposes that they should be able to estimate the resulting anæmia of the brain by post-mortem examination. Their experiments were very numerous. They were testing the results of a simple mode of treatment of the brain: they had it in their power to place the bodies in any position they liked or in any circumstances of temperature, etc., and they knew accurately the conditions actually allowed. This is what they say as the result of their investigations:—

"We could never deduce any results from the post-mortem examinations undertaken with a view to determine the state of fullness before death of the most important parts of the vascular system, namely, the arteries and arterial capillaries, and even in the most favorable instances, when similar inquiries were directed towards the veins, our results could only be looked upon as approximate."

With regard to the signs of chronic or recurrent congestion—the presence of varicose and tortuous veins, the sieve-like appearance of the cut surface (*l'état criblé*), due to dilatation of the perivascular spaces, the presence of blood crystals, and the like, Moxon's criticisms seem to us equally pertinent. Real varicosity of veins, he says, he has never seen in a single one of the several thousand examinations which he has conducted. It cannot therefore be a very common condition. An appearance of temporary tortuosity and local overfilling is, to be sure, often enough observed, but its significance is neither greater nor less than that of the general overfilling which has just been commented upon. For the condition characterized by the sieve-like appearance of the cut surface (especially noticeable in the corpus striatum) Moxon offers an explanation which is at least as plausible as that commonly adopted, namely, that it is due to a shrinking of the brain as a result of degenerative changes, which may be natural (senile) or pathological, and which makes itself manifest in the neighborhood of the vessels for the same reason that it does so over the convexity, that is, because both are parts where the lymph can flow in to supply the place of the atrophied tissue.

As to the presence of hamatoidine and other signs of disease and rupture of capillary vessels, Moxon says that for years he was in the habit of cutting out a cubic inch of brain tissue from the neighborhood of the island of Reil in every brain which he examined and studying carefully the condition of the vessels in it, and that he found these changes to be far from uncommon, even in brains which there was every reason to consider normal. He refers them to such causes as slight injuries to the head, saying with justice that when a person over twenty-five years of age declares himself to be in good health his statement has only a relative value.

Large hemorrhages into the brain may destroy life, but small ones do not, and may, indeed, pass unno-

ticed, or cause temporary symptoms which are soon forgotten, though traces of the lesion that caused them remain behind.

To refer, then, slight lesions to past congestions is to make, in the present state of our knowledge, a gratuitous assumption, and one which would perhaps never have suggested itself had it not been that the admission of the clinical diagnosis seemed to require it. But, in fact, the clinical diagnosis is based upon the observation of *acute* symptoms, and in so far as without anatomical justification. If, as has been shown, acute congestion is impotent to provoke serious symptoms, its power to cause capillary hemorrhages, even if it exists, loses all clinical interest.

It is, in fact, quite true, as Moxon says, that if we read chapters on this subject in our best text-books we find that it "gathers groups of symptoms of a disease called 'congestion of the brain,' and collects signs of morbid anatomy of the disease so named, and this gathering of symptoms includes a sweeping together of all such things as are obscure, and associated with stupor, and have an acute course, and the collection of anatomical signs includes a sweeping up of all the marks of change in the texture and blood-vessels of the brain, however evidently chronic and ancient. And the collection of chronic and ancient changes stands there to the gathering of acute and obscure symptoms as the morbid anatomy of a definite and fatal disease, — congestion of the brain."

If, now, we examine more closely the *symptomatology* of the so-called congestion, we find (still following Moxon, who adopts the usual classification) four prominent forms described, namely: the convulsive or epileptiform, the apoplectiform, the febrile, and that characterized by delirium, and usually occurring in old persons. To these might be added the form described by Hammond and others, and characterized by cerebral exhaustion of greater or less degree.

With regard to the *two former*, for an account of which we would warmly recommend the reader to Moxon's analysis, we do not think it necessary to go into the differential diagnosis at length. Their names really contain all that is known about these conditions, and there is but little use in making out of them "an epilepsy which is not quite epilepsy, or sunstroke that is not quite sunstroke, and alcoholism which is now changed so that it is deserving to be called no longer alcoholism but congestion of the brain." As we really know almost nothing of the pathology of any of these states, it would seem to be an unnecessary piece of labor to attempt to divide them into pathologically different groups so long as the clinical distinctions are of secondary importance.

As to the *apoplectiform* variety, so good an observer as Trousseau is quoted as saying, "During the first years of my practice I saw a pretty large number of cases of apoplectiform congestion, but for a long time I have not seen any. Yet other medical men see as many as before. Let us therefore inquire on whose side the error lies."

With regard to the *febrile* form, if congestion be present, — for which view Moxon thinks there is not the slightest proof, — it is strange that the cold-water treatment, which contracts the vessels of the periphery and should therefore help to congest those of the brain, is often the one that gives the greatest relief. Of this he gives a striking instance in the case of a patient with rheumatic fever with cerebral symptoms, where

bleeding and other antiphlogistic treatment had previously been tried in vain.

The *fourth form*, that characterized by delirium. Moxon believes to be cerebral exhaustion due to degenerative (senile) changes, and probably associated with *impaired cerebral circulation*.

As for the variety with which Hammond's name is largely associated, and which often occurs as a chronic condition in persons well enough to go about the streets, and even to do more or less active business, his own arguments are so little marked by a spirit of scientific criticism that we feel justified in passing them by without comment. The mere fact that he claims that in persons suffering from these symptoms, which he has seen and cured by the hundred, the optic disk is often so congested as to deserve the name of "choked disk" or "congestion papilla," must throw a veil of discredit over his views in the minds of those accustomed to judge carefully of the value of ophthalmoscopic evidence.¹

"Choked disk" is now well recognized to indicate nothing more nor less than neuritis, and although neuritis may of course come and come and go without seriously interfering with sight, no reliable ophthalmoscopist of the present day would venture to refer it to simple increase of the cerebral circulation. Even if we grant that healthy intellectual activity increases the flow of blood to the brain, and that during sleep the brain is anemic (and the latter doctrine is probably not correct in the sense that cerebral anemia is necessary to or the cause of sleep), it is a bold leap to the conclusion that hyperemia attends excitement and wakefulness, to say nothing of its being the factor primarily responsible for these or similar states.

In like manner, to conclude from a "venous hyperemia" of the retina (ordinarily impossible to diagnose without familiarity with the usual appearance of the individual retina), or from a pinkish tympanic membrane, that the brain is surcharged with arterial blood, is, in the present state of our knowledge, an unwarrantable step.

Moxon concludes this part of his subject as follows: "I have thus far endeavored to establish these propositions: *First*, that atmospheric pressure so great as to force blood into the vessels of the brain more thoroughly than could be done by any intrinsic forces of the circulation does not produce cerebral symptoms. *Second*, that strangulation and carbonic-acid poisoning lend no support to a supposition of independent congestion of the brain. *Third*, that morbid anatomy is unable to show any evidence of general overfilling of the blood-vessels of the brain. *Fourth*, that in the diseases described as congestion of the brain clinical evidence of overfilling of the cerebral vessels is utterly wanting, and that the state of the circulation present in these disorders can be shown in typical instances to be the reverse of an overfullness. From all this it follows that there is no pathological justification for our setting up congestion of the brain as a distinct kind of disease, nor for our attempting to explain cerebral symptoms by the assumption of congestion of the

brain. For the forcing of blood into the brain while the blood is good and properly aerated, and is within its vessels, affects only favorably the functions of the brain as far as our evidence goes."

We regret not to have space to speak of Moxon's views as to the anatomical arrangements of the circulation in the brain, — though indeed they call for expert criticism, — but will refer briefly to his examination of the doctrine which regards *anæmia of the brain*, due to arterial spasm, as the cause of *epileptic paroxysms*. It is well known that this doctrine, in spite of the many arguments which have since then been adduced in its favor, is based essentially on the celebrated experiments of Kussmaul and Tenner, who found that ligation of the cervical vessels, if sudden and complete, is capable of exciting convulsion in certain animals.

These last words, "if sudden and complete," contain the key of Moxon's criticism. For he shows reason to believe that such contraction of arteries as is brought about through the agency of the vaso motor nerves is neither so complete as Kussmaul and Tenner found to be necessary in their experiments, nor nearly rapid enough to account for those epileptic attacks which come on like a flash, causing the patient to fall as if struck down by a blow, it may be into the fire or the water. On the contrary, such a vaso-motor contraction requires five to ten seconds for its development.

A more probable cause of the convulsions Moxon finds in cessation of the heart's action, which both he and others have observed to usher in the epileptic seizure.

Reports of Societies.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

FEBRUARY 12, 1881. DR. HOSMER read a paper on

TONIC SPASM OF THE INTERNAL OS,

which will be found on page 368 of this number of the JOURNAL.

Dr. Hosmer stated that in the first paper he had made reference to Bandl, who first reported excessive elongation of the cervix originating primarily in some pelvic deformity, one lip being caught between the head and the pelvis. In McDonald's case there was no relation of the condition to pelvic deformity.

Dr. RICHARDSON asked why pelvic deformity should be thrown out of McDonald's case, stating that it was difficult to detect a slight deformity.

Dr. HOSMER said that they were not, as Duncan's cases were, those of excessive elongation of the cervix without spasm of the internal os, and which were delivered without difficulty.

Dr. BLAKE questioned whether these were cases of pure spasm or to some extent the result of inflammatory action, such as might result from the combination of pressure and deformity.

Dr. SINCLAIR thought we had no more right to infer an inflammatory character in this than in other tetanic states of the uterus which do not yield.

Dr. RICHARDSON said that in Bandl's cases no local lesions were found, the only pathological condition noticed being that in many of the cases rupture of the uterus had taken place at the line of the constriction

¹ "Ophthalmoscopic examination shows the arteries of the retina to be increased in size and tortuosity, and vessels which in health are not visible are now clearly perceived. The optic disk is often more or less congested, exhibiting the appearances to which Allbutt has applied the name 'congestion papilla,' but which is perhaps more generally known as 'choked disk.' The tint of the choroid is deeper than it is when in a normal condition." (Cerebral Hyperemia, Hammond, 1878, page 40.)

from attenuation, aided, or perhaps induced, by the hand or attempts to introduce the forceps.

PRIMITIVE CANCER OF THE VAGINA.

The paper was read by DR. CURTIS, and will soon be published in the JOURNAL.

DR. LYMAN referred to a case of this disease reported by him at a previous meeting.

DR. BIXBY reported a case of primitive cancer of the vagina.

This was in the person of a lady in high life, a multipara aged fifty. The growth, the size of a half-dollar piece, was discovered a year previous. The local suffering was insignificant, but the general health was profoundly affected. The ulcer was confined to the mucous membrane, quite movable, and easily and apparently completely removed, leaving a clean wound, which was brought together with silver sutures. In the course of ten days the parts were firmly united, but there was no improvement in the general health. Three months later the disease reappeared in the cicatrix, infiltration of the vaginal wall and perimetrium soon followed, and the case terminated fatally six months after the operation. In another case Dr. Bixby would use the cauterizer instead of the knife.

DR. CURTIS remarked that in this case the progress was very rapid, the woman being confined to the house not over a month.

DR. SINCLAIR stated that on the other hand sessile polypoid growths from the vagina have not returned even when, as in a case in this city, they have been pronounced malignant by a gynecologist.

MASSACHUSETTS MEDICAL SOCIETY; COUNCILLORS' MEETING.

OCTOBER 5, 1881. The stated meeting of the Councillors was held at the Medical Library Hall at eleven A. M., October 5th, the President, DR. WILLIAMS, in the chair.

After the transaction of the usual routine business — the selection of delegates to the meetings of the New York and Vermont Medical Societies, the remission of certain assessment dues, and the direction to the treasurer to collect other dues by legal process — the Councillors listened to the report of a joint special committee appointed at the annual meeting "to consider the relative rights of the Council and Society to originate amendments to the by-laws," and to report "whether it is desirable to formulate a new code of by-laws." The report declared that "it is not necessary to formulate a new code of by-laws, it having been ascertained from the records of the Council and Society that the last edition contains and includes all the by-laws that are now in force." The committee recommended, with reference to the other matter before them, that the following be adopted as an amendment to the present rule governing such actions: "In all changes of the by-laws, requiring, as they do, a concurrent vote of the Councillors and Society, the action of the Councillors shall precede that of the Society; but it shall be competent for a Fellow at any meeting of the Society to propose any alteration of any by-laws and the said proposition shall at once be referred to the Councillors, and, in case of its adoption by the Councillors, it shall be submitted again to the Society for final action."

The presentation of this report initiated an animated discussion.

DR. HODGSON said the committee's plan proposed to substitute a clumsy method for accomplishing that which under the present rules was easy and plain. He saw no reason for any change.

DR. S. CABOT said that the only change proposed appeared to him to be that in amending by-laws the action of the Councillors should precede that of the Society, and he thought the committee might have said so in simple terms.

DR. G. C. SHATTUCK suggested that as doubt seemed to exist in some minds as to the questions presented in the committee's report, it would be proper to re-commit the subject if the Council were not ready to accept the proposition recommended.

DR. H. I. BOWDITCH said that by twenty years' usage the Councillors had assumed the right to originate action touching the by-laws, and as a member of the committee he had insisted on that part of the proposed amendment which permitted a Fellow at any meeting of the Society to offer an amendment.

DR. HODGSON claimed that the Society's charter gave the right to the Society to originate amendments and nowhere prohibited it. The effect (though, perhaps, not the intent) of the committee's proposition would be to postpone for a whole year the presentation of any measure for the admission of women to the Society; therefore he opposed the adoption of the report.

DR. G. C. SHATTUCK reminded the meeting that the Council was essentially a representative committee of the whole Society, designed to facilitate the Society's business and administration; and just as in other similar associations or assemblies, measures are first considered and reported upon by committees, so here the fairer way in disposing of business would be that the Council, the smaller body, should initiate action.

The president stated that for nearly forty years the rule that the Councillors should act first upon amendments to by-laws had been departed from on one occasion only, and then, as the record said, "amid great confusion." The committee's proposition was in effect simply a confirmation of this usage, establishing a convenient method of procedure.

DR. FRANCIS was well aware of the custom alluded to, but he condemned it as discriminating against the Councillors who resided at a distance from Boston, the place of meeting, and who really represented, in his opinion, the sentiment of the Society better than the Councillors of Suffolk district.

Finally, upon motion of DR. MORRILL WYMAN, the Council voted almost unanimously to indefinitely postpone the whole matter.

DR. H. I. BOWDITCH moved that a committee be appointed to obtain legal advice upon the question whether the censors of the Society could, in conformity with the charter, examine women as to their qualification to practice medicine, and, if such women were found to be qualified, to give them a diploma or certificate to that effect, without, however, admitting them to be members of the Massachusetts Medical Society.

The president explained that the charter explicitly declared that candidates who passed the examination of the censors became by that fact Fellows of the Society.

DR. BOWDITCH argued that the present policy of the Society was to drive women-physicians into quackery or to study medicine at small medical schools or

beyond the sea. He proposed his plan as a compromise measure whereby the community should know who are educated women and who are not; he would have the censors examine all candidates without regard to sex and certify concerning their qualifications. The power granted by the charter to the censors to admit candidates to fellowship certainly implied the lesser power to examine candidates and to give them a certificate of proficiency.

DR. LYMAN asked Dr. Bowditch to point out in the charter any clause which permitted the action which he proposed. As a matter of fact, there was no such half-way stage at which women physicians could stop; the censors must either make them, under the charter, members of the Society, or must reject them from membership.

DR. SHATTUCK was opposed to the motion to apply for legal advice, both because it is costly and because it is partisan and unsatisfactory. The only final method of securing the legal determination of the question involved is by a suit brought before the highest court. Anything short of this was simply assaulting the bulwarks; it did not meet the main issue.

DR. HODGSON deprecated expending any more money for legal opinions.

The question upon the adoption of Dr. Bowditch's motion being put, it was lost by a unanimous vote.

The corresponding secretary, DR. SWAN, read letters from Drs. Sampson Gamgee, and William Bowman, of London, accepting the honorary membership to which they had been elected.

THE NEW YORK ACADEMY OF MEDICINE.

THE RECENT PROGRESS OF PERITONEAL SURGERY: DOES IT LEAD TO A BETTER TREATMENT OF GUN- SHOT AND OTHER WOUNDS OF THE ABDOMINAL CAVITY.

At a stated meeting of the Academy, held October 6th, Dr. J. Marion Sims read a paper on the above subject. After alluding to the wonderful advances that had been made in this department of surgery during the past few years, especially as set forth in the papers and discussions at the recent International Medical Congress in London, he took up a number of the most important points and methods of procedure adopted by the best authorities in abdominal surgery, and dwelt particularly on the subject of drainage. Listerism and drainage, he said, were intimately associated, and had had their rise almost simultaneously; but in the brilliant achievements of Professor Lister the no less useful labors of Chassaignac, the originator of modern surgical drainage, had been to a great extent lost sight of. In all amputations, particularly, drainage was of the most vital importance, and if in any case he personally had to choose between Listerism and drainage he would undoubtedly select the latter, with a view to the best chances for the patient. If drainage was of so much importance in general surgery, then, why should it not be more frequently resorted to in abdominal surgery? It had been conclusively demonstrated that there was no great danger in introducing a glass tube into the peritoneal cavity. Yet Spencer Wells had discarded the use of the drainage tube entirely, on the theory that Listerism renders the peritoneal fluids entirely aseptic, and that their absorption is not, there-

fore, attended with danger. Dr. Sims feared, however, that this was not in reality the fact, and, in support of his position, mentioned a case in which he had himself seen Wells operate. It was a very bad one, with numerous and firm adhesions, and when the external wound was closed there was still some oozing. For thirty-six hours (as frequently occurred in such instances) the patient did perfectly well, but at the end of that time she began to grow rapidly worse, and her life was saved only with the greatest difficulty. There was seen to be some bloody oozing from the lower end of the wound, and, in consequence, Mr. Wells removed some of the sutures and thoroughly washed out the cavity, when the patient began to improve again, and finally made a good recovery. One unfortunate feature of drainage in ovariectomy was the tendency which it had to result ultimately in ventral hernia, and the prevention of this was an important problem that was yet to be worked out. Still, he believed it was better to risk the chance of ventral hernia than that the patient's life should be sacrificed for fear of its occurrence. In connection with the subject of ovariectomy he stated that the use of the clamp had now been given up by all the great operators in England, and remarked that the clamp and Listerism were antagonistic.

Dr. Sims then went on to speak of the other important operations which have grown out of that of ovariectomy. The first mentioned was extirpation of the uterus, which, he said, had first been successfully performed in this country by Kimball, of Lowell, and the late Dr. John T. Darby, formerly of South Carolina, but at the time of his death professor of surgery in the University of New York, and gave a detailed description of the method of Péan, who had met with the greatest number of successes. In his hands the operation was a very tedious one, as the peculiarity of his plan was the removing of the uterine tumor piecemeal, namely, by dissecting out successive segments of the mass, which had first been secured by a parallelogram of constricting wires. Finally, he made a pedicle of the cervix and broad ligaments. He also mentioned some modifications of Péan's method, which rendered it much less tedious, and stated that the late Dr. Wright, of Cincinnati, had met with greater success in the operation than any other American surgeon.

Dr. Sims spoke for some time of the extirpation of the kidney, as first practiced by Simon, and the later operation by abdominal section, which had now been done six times, and was first performed by Martin, of Berlin. He believed that there was a future for the last-named operation in the case of floating kidney, while the lumbar section was more available when the organ was fixed. Lawson Tait, whom he regarded as the most daring and successful operator in abdominal surgery of the present generation, had performed no less than six operations for pyo-nephritis, and they had all proved successful. He then described a case of dropsy of the gall-bladder in which he had himself operated, where the operation was performed with perfect success, but the patient had afterwards died from septicæmia in consequence of the procedure having been too long delayed. In a similar case, under the hands of Lawson Tait, the patient had made a good recovery, and the same surgeon had operated six times successfully in hydatids of the liver, the drainage-tube in these cases bearing an important part in the accomplishment of the good result. Wounds of the bladder, whether from a knife, a bayonet, or the horns of

a bull, could also be successfully treated by means of sutures and appropriate drainage.

Dr. Sims next took up the subject of Battey's operation, which he dwelt upon for some time. The fame of Battey, he said, would endure, because the procedure had now won for itself an established position in surgery. Its victory had been easier than that of ovariectomy, for the reason that the one was simply a corollary of the other. Its success was plainly indicated by the fact that Lawson Tait had already performed the operation seventy times. Twenty-six of these operations had been in cases of uterine myomata, and in this number five patients died. Of course, it was not to be undertaken in such cases unless there was serious danger to life. The operation had become perfectly legitimate in England, and Thomas Sawyer had performed it thirty times without a death. Battey had always insisted that every particle of the stroma of the ovary should be removed, but Tait went still further, and included the Fallopian tubes in the parts excised. Dr. Sims claimed that the difficulties of the operation were very materially diminished by the aid of his uterine retractor, by means of which the ovaries could be rendered much more accessible to the surgeon.

After alluding to the triumphs of gastrotomy and Billroth's excision of the pylorus, he remarked that the Cæsarean section was going out of vogue, and said that the want of success in the operation had been undoubtedly due (as any one reading the literature of the subject could see at a glance) to the entire absence of every precaution to prevent sepsis in the various cases reported. With the light that science now sheds on the subject, there was no reason why the skill of modern surgery should not give this old operation a well established position.

Then alluding briefly to the results obtained by Porro's operation, laparotomy, and lumbar colotomy, he took up the subject of Fallopian pregnancy. One of the deputy coroners of New York, in the course of his professional duties, had met with no less than seven cases of this during the past ten years. Some years ago he had seen a case with Dr. Henry D. Nicoll in which he did not doubt that the patient's life might have been saved if prompt interference had been made. When Dr. Nicoll was called in, soon after the rupture of the cyst, he recognized the condition of affairs, and correctly diagnosed the limited accumulation of blood that could be detected from the rectum, but when he himself arrived the blood had accumulated to such an extent in the pelvic cavity that the diagnosis was not so evident. Under the circumstances he hesitated to open the abdomen and secure the bleeding parts, and so the golden moment was lost, and the woman died of death. In a similar case now he would not hesitate for an instant to operate.

With the exception of the operation of ovariectomy all the great advances in peritoneal surgery had been made within the last ten years, but its principles and practice were already so fully recognized that the path was open to even more brilliant results in the future. In 1872 Dr. Sims published a paper in which he showed that after injuries and operations involving the peritoneal cavity septicæmia, and not peritonitis, was the usual cause of death. Some years since, while sojourning at Cooper's Well, the waters of which were so efficient in the treatment of the chronic diarrhoea which is so frequent and fatal in the South, he had

seen a number of patients suffering from this affection perish from perforation of the intestines, and he had found that they died from septicæmia and shock, and not from peritonitis. He then alluded to the well-known cases of Albert Richardson and James Fiske, in New York, both of whom perished from gun-shot wounds of the abdomen, and both of whom, he thought, might possibly have been saved if the peritoneal cavity had been opened by the surgeons in attendance. In the former case, although the liver, stomach, and ileum were injured, the patient lived for eight days, and after death thirty-two ounces of bloody serum were found in the abdomen. In the case of Fiske, the pistol-ball entered the body six inches above the umbilicus, and caused two perforations of the ileum, which he thought might have been reached and sutured, but he died of shock and septicæmia, and at the autopsy from four to six ounces of bloody serum were found in the abdominal cavity. Wounds of the peritonæum, however made, had a common course to run, and were all amenable to the same treatment. Peritonitis was the exception, rather than the rule, in such cases, and even if it did complicate a septicæmic case, it need make no difference whatever in the treatment pursued. This was plainly recognized in ovariectomy, but there was no reason why the triumphs achieved in consequence of this knowledge should be confined to a special branch of abdominal surgery. In every case of injury involving the peritonæum it was plainly the duty of the surgeon to open the abdomen, clear out the peritoneal cavity, secure the bleeding vessels, and suture the lacerated parts. In illustration of the importance of the subject, Dr. Sims narrated the case of the late distinguished Dr. George McClellan, of Philadelphia, who perished from intestinal perforation in the prime of manhood, and whose valuable life, he thought, might undoubtedly have been saved if the principles he was now endeavoring to inculcate had been understood at the time.

When in charge of the Franco-American ambulance train in the French-Prussian war, Dr. Sims hoped to have an opportunity of putting his views in regard to the treatment of gun-shot wounds into practical effect, but circumstances had conspired to prevent this. At Sedan he saw more cases of wounds of the abdomen, all of which proved fatal from shock and septicæmia, and in all of which an effusion of reddish serum was found after death. It might be stated as a general rule that in gun-shot wounds of the abdomen situated above the brim of the pelvis, the natural tendency was towards a fatal issue, while if the injury was at a lower point, the reverse of this was true. In the cases seen by him and his first assistant, MacCormac, at Sedan, there were seven patients shot through the pelvis, all of whom recovered, while the seven shot through the abdomen, as just stated, all died. Four similar cases had been reported by Major Gardner, of the United States medical service, who was present at the meeting. The statistics of the Crimean war showed that ninety-two per cent. of all gun-shot wounds of the abdomen proved fatal, and it would be interesting to inquire whether, in the eight per cent. of patients who recovered, the injury was not located below the brim of the pelvis. The reason for the difference in the two classes of cases was, that in the pelvis there was a natural drainage, while if the wound was higher up the bloody serum accumulated in the peritoneal cavity, and septicæmia resulted because there was no out-

let for it. Dr. M. A. Pallen, now of this city, had seen some frightful cases of abdominal injury during the war get well, for the reason that the wounds were of such a character that sufficient drainage was afforded. Dr. Newell of New Brunswick, who was also present, had had a most remarkable case thirty-four years ago, and had treated it in such an admirable manner that the patient was alive to-day to tell of his escape. The external wound, which was made by a fowling-piece, was situated just below the sternum, and after free purgation the man passed no less than twenty-nine shot by the rectum. Not long afterwards three shot were found just under the skin in the left lumbar region, and on making a free incision in this locality Dr. Newell succeeded in removing quite a large mass of foreign matter, which consisted of the wadding of the charge and pieces of the patient's clothing. The distinguished Clement L. Vallandigham, of Ohio, had perished from the accidental discharge of a pistol in his own hands, which resulted in fatal internal hemorrhage, but he did not doubt that if the abdomen had been opened, and the lacerated vessels secured, his life might have been saved. He did, in fact, telegraph to the surgeons in charge to adopt the procedure, but his advice was disregarded. Hunter McGuire, the well-known surgeon of Richmond, had had an immense experience in gun-shot wounds of the abdomen during the late war, and he was happy to state that he was now an advocate of his views on this subject.

Dr. Sims then took up the consideration of the case of President Garfield, which had attracted such universal attention to the subject of abdominal wounds, and stated that as he had been subjected to considerable criticism in some quarters on account of the cable dispatch which he sent to the surgeons in Washington, it was principally in vindication of the position that he had then taken that he had engaged in the preparation of the present paper. As the President did not die within three days after the reception of the injury, however, he said he knew that the abdominal cavity had not been entered, and that there was a good chance of his recovery. But if there was undoubted evidence that the ball had traversed the peritoneal cavity, and if he had recovered from shock, it was the correct thing to open the cavity and secure the patient against septicæmia. "This I said at the time, and this I say now," continued Dr. Sims, "and I stand ready to defend my position with all the ability at my command." He then went on to say that, fortunately, in the President's case the ball did not penetrate the peritoneal cavity, and this placed the case outside the present field of discussion entirely. The wound was a flesh and bone injury, and he had no criticisms whatever to make in regard to its management. When ninety-seven per cent. of cases of ovariectomy could be saved, he thought it was time that it should be understood that the same success could be obtained in gun-shot peritoneal wounds. It had been said that opportunity made the man, but the man must be prepared to seize the opportunity, and he was now eagerly on the watch for the man and the opportunity to demonstrate beyond a question the correctness of his position on this important subject.

The general conclusions of the paper were summed up as follows:—

(1.) Wounds of the peritoneal cavity, however produced, have to run a common course.

(2.) They have a common termination in death, and that death is by septicæmia.

(3.) This is the general law in deaths from ovariectomy.

(4.) This is the general law after gun-shot and other wounds of the abdomen.

(5.) The septicæmia is the result of the absorption of bloody serum remaining in the peritoneal cavity after wounds or operations.

(6.) In gun-shot wounds of the pelvic cavity the tendency is to recovery, on account of the natural drainage in this situation.

(7.) Gun-shot wounds of the abdominal cavity prove fatal from septicæmia, because there is no natural drainage, and the bloody serum poured out becomes absorbed.

(8.) In order to prevent this it is necessary to open the abdomen, clear out the peritoneal cavity, tie the bleeding vessels, suture the intestines or other tissues requiring it, and, possibly, insert a drainage tube.

(9.) If the operation is properly performed, it is rarely necessary to make use of a drainage tube.

Dr. Sayre being called upon by the chair to open the discussion when Dr. Sims concluded, remarked that it was, perhaps, the most able paper to which he had ever listened. The author of it had covered the whole ground, and there was but little left to be said upon the subject, but he could not refrain from endorsing Dr. Sims' position as to the vital importance of drainage. Why was it that patients recovered who received pelvic wounds? For the simple reason that they were through and through wounds, and an opportunity was thus afforded for successful drainage. If the wound of the President had only been a through and through one (as, indeed, it came in reality very near being), the history of the case would have been a different one from what it was. In the treatment of abdominal wounds there were two points that demanded special attention: first, accuracy of diagnosis, and second, proper procedures for the securing of drainage and the prevention of septicæmia.

Colonel McKee, of the United States Army medical service, related two cases which had occurred under his charge. The first was one of gun-shot wound of the abdomen, and was met with during the war. The patient one day, while at stool, passed the ball by the anus, and after that made an excellent recovery. In the second case, which occurred more recently, at Fort Whipple, Arizona, a man accidentally swallowed a piece of wire three inches long, and as after a time he felt it in the vicinity of the umbilicus, Dr. McKee cut down upon it and extracted it, thereby saving the patient's life.

Professor Mussey, of Cincinnati, then mentioned a case of remarkable recovery from abdominal injury caused by the horns of a bull. The patient, who was a woman, was gored twice, in each instance a gash five or six inches being made in the abdomen, and the intestines protruding to such an extent that she had to gather them up in her apron before going to the neighboring house.

Dr. Fordyce Barker, the president of the Academy, stated that the special aim of the paper was to show the importance of general surgeons availing themselves of the advances that had recently been made by gynecological surgeons, and called upon Professor James R. Wood to speak upon this subject.

Dr. Wood said that while he felt very grateful to Dr. Sims for his great paper, he believed that there were things in it which nobody else in the world would

dare to say, and he would therefore be loath to express an opinion indorsing all the points that had been maintained by the distinguished writer. In general surgery he considered it a very dangerous procedure to invade the abdomen unless an accurate diagnosis was possible in every case where it was attempted. He had now had a very extensive experience in regard to this subject, and he could not but confess that in his earlier days he had sometimes tried to find balls in the abdomen which he ought not to have looked for. He did not care to speak of the President's case; but he mentioned another somewhat similar one, in which the ball entered the left side and passed to the lumbar region of the opposite side, and the patient died from blood poisoning. At the autopsy the ball was found embedded in the glutei muscles. As to the bloody serum upon which so much stress had been laid, he was disposed to think that this was often a post-mortem phenomenon, and in many cases of autopsies after fatal septicemia he had failed to find it altogether. In wounds of the liver there was usually very free hemorrhage, and it would be impossible to control this, even if the abdomen were opened. In these cases the patients generally died within six or eight hours after the reception of the injury, and if the surgeon cut into the abdomen at all it had to be done before the patient had recovered from the shock. The chances were that death would take place while he was engaged in cleaning out the peritoneal cavity, and this would not be a very good thing for the operator's reputation. So, if in a case of laceration of the stomach the surgeon attempted to sew up the organ he would get into trouble, because, as a rule, such patients died of shock, and did not live long enough to get septicemia. In ovariectomy the case was very different, for there the surgeon could choose his own time for operating, and have his patient all prepared; but in abdominal wounds the trouble was that this terrible shock stared him constantly in the face. Dr. Wood was not willing that the gynecological surgeons should have all the glory, and finished his remarks by mentioning several cases of severe injury of the bladder and other organs in which the patients had recovered under his hands. He believed in drainage-tubes, he said, but not to the extent that Chassaignac did.

The discussion was also participated in by Major Gardner, of the United States Army medical service, and by Drs. Newell, of New Brunswick, N. J., Clinton Cushing, of San Francisco, Cal., and Leonard Weber, of New York.

Recent Literature.

A Treatise on the Continued Fevers. By JAMES C. WILSON, M. D., with an introduction by J. W. Da Costa, M. D. New York: William Wood & Co. 1881.

This book appears as a volume of Wood's Library of Standard Medical Authors. The diseases considered in its 360 pages under the head of Continued Fevers are: Simple Continued Fevers, Influenza, Cerebro Spinal, Enteric or Typhoid, Typhus, Relapsing Fevers, and Dengue. The variable and inconstant eruptions in the last named disease the writer does not regard as a sufficient reason for classifying it with the exanthemata.

The necessary retention of the old, but, as we all hope, provisional, title of this group of diseases is depicted in the preface.

Dr. Da Costa's introduction, covering a half dozen pages, is devoted to some remarks upon the management of fevers in general, remarks which are thoroughly sound though not an essential part of the book. This device of starting a younger man's book under the escort of an older man's introduction seems to be growing in favor with the parents and guardians of medical literature. In this connection it would not be amiss for them to bear in mind the old saying that good wine needs no bush.

The writer of the present volume states his object to have been the description of the diseases of which it treats with greater fullness than is usual in the textbooks, yet without the extreme elaboration that mars the usefulness of some of the special treatises. This object is attained quite well enough to make the book a useful addition to the working library of the busy practitioner, and to allow the book to stand upon its own merits.

In regard to typhoid fever, Dr. Wilson embraces unreservedly the theory that the fever-producing principle is an organized germ, a *contagium vivum*, and is disposed to reject the pythogenic or *de novo* origin of the disease. In the description of the spirilla of relapsing fever some reference to the investigations of Vandyke Carter and other recent observers would not have been amiss.

Manual for the Physiological Laboratory. By VINCENT HARRIS, M. D., and D'ARCY POWER, B. A. New York: William Wood & Co. 1881.

It has been the custom for some years at St. Bartholomew's Hospital to distribute short histological and chemical papers to the physiological students in order to facilitate their laboratory work. These papers have now been collected into a small manual and given to the public. A number of books of this character have been published, and no doubt serve a useful purpose as reference for those who are interested in microscopy, but have had no special laboratory training in the study of microscopic anatomy. This book seems to be carefully prepared, and is a fair sample of its class. Numerous blank pages are scattered throughout the book, which will be handy for notes and references.

Anatomical Studies Upon Brains of Criminals; a Contribution to Anthropology, Medicine, Jurisprudence, and Psychology. By PROFESSOR MORITZ BENEDIKT. Translated from the German by E. P. Fowler, M. D., New York: William Wood & Co. 1881.

Professor Benedikt describes the brains of twenty-two convicted criminals as studied by him post mortem. Many of the descriptions are accompanied by rather coarse wood cuts illustrating the peculiarities and deficiencies described. Professor Benedikt finds almost invariably deficient gyrus development and a consequent excess of fissures, both of them fundamental defects in cerebral constitution; in a large proportion of the cases examined the cerebellum was incompletely covered by the occipital lobes of the cerebrum.

Dr. Benedikt's observations are too few to base any positive laws upon. Moreover he was forced to pursue his study in parts of the Austrian Empire where there is no fixed race type. His observations, however, as far as they go, are very suggestive and point to a source of fruitful investigation in a not remote future.

Medical and Surgical Journal.

THURSDAY, OCTOBER 20, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.

HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

SANITARY SCIENCE JUSTIFIED BY ITS WORKS.

THOSE State legislatures and town governments which have not yet established boards of health, those which may be hesitating whether such notions pay, and certainly those politicians who may have persuaded themselves that a curtailment of the efficiency of such organizations already established, under the excuse of a little pretended economy, will in the long run be approved by the people at large, all such would do well to devote some study to the recent report of the Local Government Board, which contains, among other things, a statement of the progress of sanitary work in England and Wales. We have seen nothing of late more strikingly illustrative of the practical value of sanitary work when carried out under favorable auspices, and it offers precisely that kind of hard arithmetical testimony by which the politician who finds it ordinarily for his advantage to pose as a watchdog of the treasury may easily justify to his constituents the comparatively modest outlay of money which the suggestion and supervision of sanitary work demands of the State or the town. In fact the results are so positive, and the mere money returns are so readily deducible therefrom, that we believe the average constituent, who had not entirely neglected to secure the advantages of our common school education, would not only feel the expense justified but imperatively demanded were the figures once brought to his notice. We make the following extract from the report in question:—

"Before concluding the part of our report which relates to sanitary administration, it may be useful to draw attention to the annual death-rate for some years past as indicating the effect which recent sanitary measures would appear to have had upon the public health.

"The following table shows the death-rate for each of the four last decennial periods:—

ENGLAND AND WALES.

Annual death-rate per 1000.	1841-50.	1851-60.	1861-70.	1871-80.
All causes	22.4	22.2	22.5	21.5
Seven zymotic diseases	—	4.11	4.14	3.36
Fever	—	0.91	0.88	0.49

"From the above figures it will be seen that, speaking generally, the death-rate of the country remained stationary from 1840 to 1870, but that in the period 1871-80 it fell from 22.5 (of the previous decade) to 21.5, a reduction equivalent to nearly four and one half per cent. It may, therefore, be roughly estimated that about a quarter of a million of persons were saved from death in the ten years, 1871-80, who would have died if the death-rate had been the same as in the previous thirty years. If twelve cases of serious but non-fatal illness be reckoned for

every death, it follows that about three million persons, or over one ninth of the whole population, have been saved from a sick bed by some influences at work in the past decade which had not been in operation previously. The case, indeed, is still stronger than this. The death-rate of rural districts is habitually lower than that of urban districts; and as the population is steadily concentrating itself more and more into the towns, the death-rate of the whole country would tend to increase, if the other circumstances affecting it remained the same. When we find that this tendency has been so much more than merely counteracted, it becomes interesting to see where the gain has been, and to endeavor to trace some of the causes to which it may be due.

"Comparing, then, 1861-70 with 1871-80, it will be seen from the foregoing figures, that of the entire reduction of 1.0 in the death-rate, more than three quarters ($4.14-3.36=0.78$) comes under the head of "the seven zymotic diseases," of the diseases, that is, which are most influenced by sanitary improvements, and most amenable to control by the action of sanitary authorities. And of this three quarters, just half ($0.88-0.49=0.39$) or three eighths of the entire reduction, is in "fever," the disease which, more than any other, shows itself in connection with such faults of drainage, of water supply, and of filth accumulation, as it is within the province of good sanitary administration to remove.

"It is particularly significant that since the year 1870, when the fever death-rate was 0.80 per 1000, it has fallen pretty steadily, year by year, as follows, down to 0.32 in 1880:—

187170	187644
187261	187741
187358	187842
187459	187930
187555	188032

"Thus in the five years, 1871-75, the fever death-rate was 0.61; in the five years 1876-80 it was 0.38."

The Board in making this gratifying and honorable statement credits its efforts simply with the deaths and sickness avoided by the influences which have been quietly brought to bear largely through its agency. To some minds, however, escape from sickness, with a consequent increase of capacity for activity and happiness, appears only in its full beauty when placed upon a strictly cash basis. For the benefit of law makers and constituents of this class we repeat some of Mr. Edwin Chadwick's comments upon the above statement. Mr. Chadwick says:—

"During the decade from 1861 to 1870, there appeared to be no gain from the outlay on sanitary works or on sanitary service in England and Wales; but since then the service appears to have made an effective start, and the pecuniary gain may be thus stated: Under the inquiry as to interments, the cost of funerals—all round—was ascertained to be £5 pounds each. The gain under that head will, therefore, be about one million by the quarter of a million of funerals saved during the last decade. The direct cost of sickness has been estimated at about £1 per case. The gain under that head during the decade will therefore amount to about three millions; a gain, that is to say, of medical treatment and other expenses. But the gain to the wage classes, from the saving of lost labor, will have been far greater. Dr. James Watts, who has had great experience in friendly societies, states the average loss of working time at two and one half working weeks per member between twenty-one and seventy years of age, and he estimates the total loss to the wage classes, by the loss of work through sickness, at upwards of thirteen millions per annum. The gain derivable from sanitation may be further illustrated from its advance in military service. The first British army went out to the Crimea under the established curative or medical service, and it was lost. Sanitary Commissioners, trained in service under the first General Board of Health, were then sent out to reform the condition of hospitals and camp, and within three months reduced the sickness and mortality from a plague-rate down to an ordinary standard of health, and by the end of the summer of 1855 to a rate lower than that of the best hospitals at home; and the War Minister declared in Parliament that by the application of their science the second army had been saved. Since then, the Army Medical Department has applied extended sanitary operations. Their exercise under great difficulties is best shown in India. Formerly the death-rate in the Indian army was 69 per 1000 per annum. The aver-

age mortality from 1899 to 1878 was only 20.41. There was, therefore, a gain of 48.59 per 1000; or, on the present force out there, a gain of 2350 men. The death-rate of the army at home was formerly 18 per 1000. In the year 1879 it was 7.55, being a gain of 10.55 per 1000. As the strength of the army in 1879 was 80,700, the gain was 843 per annum. The total gain to the army in India and the army at home, and the rest of the army will be 3113 men, per annum. As each soldier is estimated at £100, this represents in money value £311,300, or more than a third of a million. It is not very easy to get at the real amount of the sickness; but the total gain, including the diminished death-rate, is considered to be underrated at half a million per annum. The deaths by steam explosions, in mines and on railways, amount to about five thousand annually, but the lives saved by the civil sanitary service in England and Wales are five-fold greater than the lives thus destroyed by civil accidental violence. A reduction of the death-rate by four and one half per cent. is only an instalment of sanitary progress. Thus, in the instance of Croydon, visited by the delegates of the Congress, the death-rate has been reduced from 25 to 16 per 1000, chiefly by the methods introduced by the first General Board of Health, by which spring supplies of pure water are carried into the houses, and the fouled water carried at once out of the houses and out of the town, by one Local Board authority, while all putrescible matter, instead of remaining for months and years in conditions of putrefaction, is undecomposed, and flows upon the land within two hours. So in Salisbury, Leamington, and a number of other places. At Croydon, it has been stated by Dr. Alfred Carpenter, that, by complete sanitation, the death-rate might be reduced to ten in a thousand. In the metropolis the death-rates amongst the wage classes in their common dwellings is upwards of thirty per thousand. In the model dwellings, in London, it is, however, about sixteen or seventeen, even with surrounding deteriorating conditions. On the demonstrations of various model instances, it may be held that the reduction of the general death-rate by one and one fourth per cent., as reported, satisfactory as this is, cannot be considered more than one third of the results obtainable by advanced sanitary administration and further sanitary works.

No science, no organization, and no individual can be subjected to a more searching test of efficiency than the character of the works it produces. Sanitary science, as exhibited in this statement of the Local Government Board, which is merely typical of work actually doing and work that may be done in many other parts of the world, is certainly justified of her children.

As he observes, the estimates given by Mr. Chadwick serve to show the money loss incurred by inattention to the continuance of preventible physical evils, but the pain and misery, and the social disorders, occasioned by excessive sickness and premature mortality are generally beyond pecuniary estimation. Hence, the civilized state of the present day cannot afford to have anything short of the most efficient attainable organization of its sanitary service, and any neglect to secure this, no matter from what motives, will be sure to revenge itself sooner rather than later. The more civilized the state the more imperative the demand upon it and the greater the responsibility incurred by its officers.

CHEAPNESS IN THE CARE OF THE PAUPER INSANE.

THE *Boston Daily Advertiser* of September 15th contains some facts with regard to the detention of insane people in almshouses which are well worth careful consideration while the spirit of "economy" is urging so many towns to return to the old method so long and successfully fought against in this State of treating the pauper insane and other paupers together. It seems that a man sixty years of age, who had been an inmate of the

New Bedford almshouse a number of years, being paralyzed on his left side, showed symptoms of insanity, so that it was necessary to confine him in the yard to prevent him from escaping, which he attempted several times. On one occasion being prevented from passing out by the doorkeeper he dealt him a severe blow upon the head with his cane, and presently made a second attempt, which was prevented by an officer, and his cane taken from him. The doorkeeper having charge at that time was seventy-five years of age, and was only occupying the position for a day or two, while the regular one was away. The offender next struck an inoffensive inmate a hard blow on the arm without the least provocation. One day as the boys stood in line preparatory to going to their breakfast, he struck one of them in the face so as to break the skin. The officer being present prevented any further trouble at that time. This was also without cause. He a second time attempted to escape, but was arrested by the doorkeeper and was found to have a stove-wrench secreted under his paralyzed arm and an old sheath-knife in his right hand. He was then placed in close confinement. About the same time an old man about eighty was standing in the doorway, when a "harmless" inmate discharged from the Taunton insane asylum eight years ago, but troublesome at times, came along and struck him an awful blow over the eye, which not only felled him to the floor, but across the door-step and hurt his back, from which he has not yet recovered, and perhaps never will. The blow was sufficient to break the skin on the eye. He next struck a man about seventy, but this time he found his match and was overpowered. He next made a pass at a boy, but the boy was too quick for him. He then struck one of those previously struck, and has since struck an idiotic inmate twice. The last time it was in the presence of an officer who had a plate of food in each hand, and was struck a stinging blow behind the ear. Within a few days of these occurrences, in the outskirts of Fall River, a man entered a blacksmith shop. On his ankles were a pair of shackles, to each of which were attached a few links of broken chain. The shackles were of iron, similar in shape to the iron thimbles used on the rigging of vessels. The ends of the shackles were joined by an iron bolt and screwed nut. The stranger uttered not a word and silently picked up a wrench with which he succeeded in taking off the bolt from one of the shackles, thus removing it from the ankle. He then attempted to take off the other shackle, but the bolt resisted his efforts, and throwing down the wrench, he went out without a word. He was afterwards picked up by the police, and proved to be one McAvoy, transferred to the Fall River almshouse from the Taunton asylum.

There could be no better illustration of the folly and inhumanity of the unwise and cruel treatment that is pretty certain to attend all efforts to treat the insane simply upon the basis of cheapness. A man apparently harmless under the restrictions of the life in an insane asylum may be and very often is, so different a person when placed entirely upon his own resources in ordinary life, or partly upon them in a charitable institu-

tion, that he becomes a dangerous, in place of a safe, member of the community in which he lives, and is treated with a degree of harshness commensurate with the fears of those by whom he is surrounded. If, as is required by Scotch law, all almshouses containing the incurable insane had entirely separate departments for them and were supervised by a competent lunacy commission, there could be no reasonable objection to that method of dealing with the quite harmless class. Every intelligent community, however, is naturally shocked at any attempt to treat men and women who are simply suffering from disease with more than the severity allotted to criminals, or to expose those who only have the misfortune to be poor to the violence and insane freaks of irresponsible lunatics.

MEDICAL NOTES.

NEW YORK.

—The various eminent lights of the profession having returned from abroad, and all the schools and societies having now resumed operations after the long vacation, the medical world in New York is once more full of life and activity. The College of Physicians and Surgeons, at which the introductory address was delivered by Prof. A. Jacobi, on the evening of October 3d, announces that the experiment, tried in 1880-81, of discontinuing the spring session and of lengthening the regular session of five months, attendance upon which is obligatory, to one of seven months, has resulted to the entire satisfaction of the faculty. The expectation that it would be for the advantage of the student to attend fewer didactic lectures a day, and thus have more time to devote to clinical study, laboratory work, and recitations, they say, has been completely filled, while the numbers of students in attendance and the material prosperity of the college have never been so great. Consequently the same plan will be pursued during the present season. Since his resignation Dr. T. Gaillard Thomas has been made emeritus professor of obstetrics and diseases of women and children, but during a portion of the session he will deliver a special course of lectures on uterine displacements.

—The first meeting of the County Medical Society this season was held on the 26th of September, when the nomination of officers for the ensuing year took place, and Dr. W. Gill Wylie read a paper on the causes of laceration of the cervix uteri.

—On Thursday evening, October 6th, the first meeting of the Academy of Medicine was held, and an immense audience, including a number of army surgeons and other distinguished visitors, assembled to listen to an elaborate paper by Dr. J. Marion Sims, entitled, *The Recent Progress of Peritoneal Surgery: Does it lead to a Better Treatment of Gun-Shot and other Wounds of the Abdominal Cavity.* A report of the proceedings on this occasion, which attracted more than usual attention, will be found on page 377 of this number of the JOURNAL.

—The Board of Health's statistics show that 28,567 persons died during the first nine months of the present year, or 4715 more than during the corresponding period of last year. The total number of deaths in 1880 was 31,866. The mortality for the last three months of the year was 8014, and if that for the last quarter of 1881 should be proportionately as great as in the first three quarters, the total number of deaths during the present year will be about 38,000, or 6000 more than in 1880. This would make the highest mortality yet recorded in the city, the next highest being in 1872, when there were 32,647 deaths. The high death-rate of that year was attributed to the prevalence of small-pox and the extreme heat of the summer.

—The Board of Health is pursuing its crusade against the fraudulent milk-dealers with great energy, and sometimes as much as two thousand quarts of condemned milk have been emptied into the street at once. In consequence of this "waste of milk," as they call it, as well as the long drought which has prevailed this year, the wholesale dealers say they will be obliged to raise the price of milk. The poor quality of much of the milk that comes to New York seems to be due to the fact that the cows in the vicinity of the city are fed to a greater or less extent on brewery grains, the use of which is said to be more extensive now than it has been for years. It is generally fed to the animals mixed with hay, oats, bran, and such articles, for if it were used exclusively the milk produced would yield no cream. Every day, it is stated, eight or ten car-loads of the stuff are sent away from the Harlem railroad depot consigned to farmers along the road. The milk produced from such materials cannot be good, and it is time that the Board of Health should adopt measures to prevent the practice.

—During the past summer 11,220 women and sick children were received at the parish sanitarium, which was kept open until the 1st of October.

—The death is announced, in his seventy-second year, of Dr. James P. White, first vice-president of the American Medical Association, and president of the medical department of the University of Buffalo, of which he was one of the founders. For many years he was professor of obstetrics in that institution, and his career was in every respect a most successful one.

PHILADELPHIA.

—The introductory lecture to the one hundred and sixteenth course of lectures in the Medical Department and to the fourth course in the Dental Department of the University of Pennsylvania was delivered by Dr. D. Hayes Agnew, J. Rhea Barton Professor of Surgery and of Clinical Surgery.

—At Jefferson College the general introductory for the fifty-seventh annual course of lectures was delivered by Professor Robert E. Rodgers, for Professor William H. Pancoast, who was prevented by a death in his family. His eldest son died of typhoid fever at Long Branch.

Miscellany.

ERASMUS DARWIN MILLER.

MR. EDITOR, — The Dorchester Medical Club cannot let pass the death of their friend and comrade, Dr. Miller, with a mere word of lament; and wishing that the profession may know more of him than his own love of quiet would ever have made known, the Club transmits this notice to the JOURNAL at the first opportunity.

Erasmus Darwin Miller was the youngest son of Dr. Nathaniel and Hannah (Boyd) Miller, of Franklin, in this State, and was born August 7, 1813. His father was one of those characters in his day and generation which a uniform education has banished from the present. He was the surgeon of Norfolk and Bristol Counties. He used, when business was dull, to drive from town to town, calling on the doctor in each place and asking there if there were any surgical cases in which he wanted "counsel;" if one were forthcoming, and one generally was, the doctor was ready at a moment's notice to cut for stone, tie an artery, or dissect a tumor from the neck. He had the degree of A. M. from Bowdoin College in 1814, and of M. D. in 1817 from both Brunswick and Cambridge; he was vice-president of the Massachusetts Medical Society. His surgical fame drew so many patients to Franklin that he had to put up a large house for a hospital. He specially prided himself on detecting "deep-seated matter," and published a treatise on the subject; his colleague was Dr. Leprellette, a French surgeon who left France during the reign of Napoleon I., and for this friend Dr. Nathaniel Miller's oldest son was named. Lewis Leprellette Miller became the well-known surgeon of Providence, and was for many years President of the Rhode Island Medical Society. Mrs. Nathaniel Miller was another of the characters of the time, whom old Dr. Emmons used to call "one of the three best women in town," — the strength of her affection for her sons being only equaled by that of her nerves. When one of them was expected home she had been seen standing at the door for hours — her cap-strings flying in the wind — watching for him. She made Leprellette remove a large cancerous growth from her breast, declining to submit to any other knife than his. She had been known, when her husband was away, to conduct operations of no small importance herself rather than keep the patient unrelieved till the doctors returned from their long drives. These particulars have been dwelt on to show the stock of which our friend came.

Dr. E. D. Miller was fitted for college at Day's Academy, in Wrentham, where he received a medal, which he maintained was bestowed to please his parents, and not from any merit of his. In 1828 he entered Brown University, where he was a great favorite, and bore the sobriquet of "the little doctor." Graduating in 1832, he studied medicine for a time with his father, attended lectures at Bowdoin, was at Pittsfield with the elder Dr. Child, taking his degree of M. D. at Brunswick in 1835, and returning to the home-stead in Franklin, where he had the advantage of his father's hospital for the perfection of his surgical studies. After practicing for a time in Franklin he married Miss Louise Clarke, daughter of the Hon. Truman Clarke, of Walspole, and established himself in Worcester for

a few months, after which he returned to Franklin, becoming a member of the Massachusetts Medical Society in 1838. In 1843 he removed to Dorchester, against the strongest counsels of his father, and upon the urgent advice of his life-long friend, the Hon. Marshall P. Wilder, who survives him at the age of eighty-three. He was soon finally settled in business in Dorchester, and having gained a special reputation for the successful practice of obstetrics early turned his attention to gynecology. It was not long before his office hours were fully occupied with patients seeking his advice in this specialty. He had a very large midwifery practice of the best kind in Dorchester and the adjoining towns, covering a great extent of territory; and although we hear of single practitioners attending two or three hundred labors in a year, — till we cannot understand when they sleep, or eat, or think, — Dr. Miller used to say that the largest number of confinements he conducted in one year was eighty-three. To most of us this conveys the notion of very hard work indeed; and when one adds to this a wide general practice and an exacting specialty, we wonder that Dr. Miller kept his health as long as he did.

We remember with admiration his consultations in midwifery; his confidence, his quickness in diagnosis, the abundance and readiness of his resources, and his indomitable courage; these qualities were doubly welcome when coupled with the cheerfulness and swift ness of his response to our call for aid.

Dr. Miller's abilities as a surgeon were less known to us, because of late years little of surgery is seen outside the hospitals; his insight into disease, mechanical tact, and sound judgment served him here as everywhere, and his surgical training was admirably adapted to secure excellence and success in his chosen work.

As a gynecologist he was less known than he deserved, because he had an unconquerable aversion to writing. The rules of our club, requiring once a year from each member some kind of written contribution, forced him to give us a paper now and then; what he wrote always taught some practical lesson in general practice, obstetrics, or gynecology, particularly the latter branches, and was made as short as possible. In the discussions his knowledge and great experience was largely drawn on for our instruction and entertainment. In 1867 he read to us, and afterwards to the Norfolk District Society, a paper on the Treatment of Endometritis by Uterine Scarification; this was published in the JOURNAL of March 21, 1867, with a cut of the modification of Lallemand's urethrotome which he devised, and which had long been known to his neighbors in consultation and conversation. This article was widely copied in the medical journals, and was noted by Dr. T. G. Thomas in his Centennial Memoir of American Gynecology. Had he chosen to write out the cases which he reported to our Club, with his comments, many additions would have been made to our medical literature of solid practical worth, and his reputation as a thinker and operator more widely spread. He was conservative, not going to extremes, nor taking up new schemes and operations because they were fresh. He had great method in conducting his business, which helped him to go through his great amount of work. Every morning at half past seven he drove out of his stable, and allowing three patients and eight miles of road to the hour, was always at home at a specified time, or was

to be found at certain given points. In 1851, when cholera prevailed, he passed a whole night in driving from one patient to another, only arriving at home to find a fresh message; he used to say he never heard of another doctor doing this.

Five years ago he began to contract his business, having suffered from supra-orbital neuralgia and sleeplessness, and excepting attendance upon the daughters of a few old friends withdrew altogether from obstetric practice. He would now and then attend an old patient, stipulating that he would make the engagement if he might set the day of labor, at full term, and induce it. Such a patient must be known to him by former confinements. He would arrive in the evening, pass a gum catheter between the membranes and the uterine walls, coil the free end in the vagina, and go to bed, to be called in a few hours to complete the labor. Such was his judgment in selecting cases, his strong confidence in himself, and his good fortune, that he was always successful when others would surely have fallen into trouble while thus giving a jog to waiting nature.

Sleeplessness was added to his neuralgic symptoms, and tired of tossing in a wakeful bed, wishing in vain for a call from some patient to occupy the hours, he would rise, have a horse harnessed, and drive twenty-five miles to Franklin, where he had a large cranberry meadow on which he had expended more than \$50,000 for flogage and other purposes, and from which he used to gather annually a large crop of cranberries. Two years ago he began to be troubled with pains which he called rheumatic, and which culminated in severe illness in 1880. Convalescence was greatly aided by a sojourn at Sharon Springs, and he returned home much refreshed, and attended somewhat to business. In the latter part of last June he went again to Sharon Springs, saying that as the first visit was for health this should be for enjoyment. On Saturday afternoon, the 2d of July, when he never felt or looked better, while chatting with friends in the shade, he was told of the President's assassination. He walked about awhile, and after retiring to his room said that the news had depressed him, and while talking about the crime he became powerless to walk; his mind was perfectly clear for three hours, and he said he knew he had paralysis. After vomiting a few times he became unconscious, and remained so till his death on Tuesday, the 5th. It had been suggested to him by one of our number that a stethoscopic exploration of the heart was advisable, but he rather evaded the examination. There was no autopsy, but cerebral hemorrhage was considered to be the cause of his death. His widow survives him, with a married daughter and two sons, one of whom, Dr. Winthrop Miller, practices medicine in Minneapolis.

Dr. Miller's personal appearance was striking. Of slender make and medium height, dressed with scrupulous nicety, his long, snow-white hair and beard, and full, keen blue eyes, made a figure not soon forgotten. A quick sense of the ludicrous, the shrewdest knowledge of human nature, a power of rapid observation, strong common sense, an unusual ability to adapt himself to any society in which he might find himself, rather than wide reading or scientific research, made him rare good company. Add to these traits the store of learning and fact gathered in forty-five years of his own practice and the home education in a professional atmosphere, and those who did not know him may

judge how much the Dorchester Medical Club will miss Dr. Miller.

Always having had a respect for religion, he joined the Second Parish Church of Dorchester in 1878. Into that church, filled with mourning friends, on the 8th of July, 1881, he was borne by the hands of members of this Club. The same hands lowered him into his grave. No one of us will have better earned his rest.

S.

A LETTER FROM KANE, A NEW MOUNTAIN RESORT IN PENNSYLVANIA.

MR. EDITOR, — The few but memorable superheated days at the beginning of September again brought forcibly before the attention the rival claims of seashore and the mountains as places of refuge, and your correspondent, strongly reminded of the quandary of Lucifer, so graphically portrayed by Milton, decided to fly to the mountains, the prospect of 100° in the shade at Long Branch with a land breeze having settled the question in favor of the highlands. Having converted the decision into action, he seizes this opportunity of justifying his course, and at the same time expressing his grateful sentiments for the physical benefits he has already enjoyed.

Among the many favorable and deservedly popular health resorts found in the course of the Alleghany Mountains, it is difficult to select any that would be universally accepted as superior to all the rest, therefore in bringing into notice a modest and little-known claimant for public favor it is not intended to institute any invidious comparison with others, but merely to call attention to advantages that it possesses in common with some of its neighbors, and at the same to set forth a few that are peculiar to it.

On the line of the Philadelphia and Erie Railroad the highest point attained in crossing the Alleghenies is known as Clarion Summit, which is more than two thousand feet above the sea-level. This is a stretch of table-land, said to be about twenty miles square, situated in Northwestern Pennsylvania, principally in McKean and Clarion Counties. From this elevation the waters of the Susquehanna, Clarion, and Allegheny rivers, respectively, flow mainly in three different directions. The summit is nearly level, and is covered with virgin forest, consisting principally of hemlock, beech, and maple except when the labors of the bark-cutter and lumberman have aided the farmer in making clearings where there are flourishing farms. At the highest elevation reached by the railroad is located Kane, which, almost unknown until within a few years, has been of late rapidly growing into favor as a health resort. This is a small town in McKean County, having several hotels and boarding-houses, where plain fare is furnished, but there is also in the place a large and superior hotel, the appointments of which are especially intended for summer visitors. Being conveniently located on the line of the railroad and near the station, the train usually stops in front of the house, an advantage appreciated by those who are unable to walk any distance. On the other hand it has the corresponding disadvantage of the noise of occasional passing trains, and the whistle of locomotives. Around the hotel is an enclosure forming a park, in whose well-shaded grounds of several acres in extent children play with perfect security. The altitude and the presence of vast numbers of forest trees, principally

hemlock, notably influence the atmosphere; it is very pure, dry, and is sensibly rarefied. Its physiological effects are very evident, it is decidedly invigorating, moderately accelerating the respiration and the pulse, and giving a sense of well-being. From personal experience we can speak of the elevation of spirits and the reviving effects of this beautifully clear mountain air; it certainly stimulates the nutrition, for an increase in weight is commonly observed; in some cases this is very decided; one gentleman who had just recovered from an acute illness gained fifteen pounds in eight days, but it is not unusual for visitors to gain two or three pounds in a week. The causes of this gain in weight are not far to seek. The pure air improves the appetite and digestion, there is an abundance of substantial, wholesome food, with plenty of rich milk from cows kept on the uplands, and finally, what is even more important from a hygienic point of view, there is an entire absence of temptation to dissipation and late hours so noticeable in many summer resorts.

As regards amusements, a good bowling alley is on the grounds, and it is surprising to see delicate persons rolling the balls, and entering into the game with considerable energy, although at home they had evidently been complete invalids, furnishing another convincing proof of the salubrity and invigorating character of the climate. The nights are always cool, and refreshing sleep is obtained. Walking in the woods is a favorite exercise in the middle of the day. The trees are of primeval forest, many of them three or four hundred years old. The ground is kept quite dry by the constant movement of the air; there is comparatively little undergrowth, and the ground is carpeted by dried leaves, the accumulation of centuries. There are in the neighborhood of the hotel no pools of water that children may fall into, but running through the woods are small mountain streams that furnish good trout-fishing for the sportsman. No poisonous plants exist in this vicinity, the smooth-leaved sumach is found, but poison ivy and similar varieties are said to be entirely absent. It is also important to note that there are no dangerous snakes whatever, occasionally a garter-snake may be encountered, but nothing larger or more formidable. Good dry roads and paths intersect the woods, and riding, driving, and walking are equally enjoyable. There are numerous springs about here, and an abundance of good water. In the spring wild pigeons fly through the woods in myriads, and afford sportsmen an abundance of shooting; in the winter deer are also killed in large numbers. Throughout the summer pheasants, woodpeckers, and other birds abound, while rabbits and squirrels are also seen from time to time crossing the path. The mountain views that unexpectedly appear through the forest well repay the tourist for a tramp, while those unable to walk far may command a fine prospect from the top of the hotel.

One of the great natural curiosities of this neighborhood and, indeed, it might be said of the world, is the burning, spouting well. Approaching the well through the virgin woods the roar of the flame can be distinctly heard for a considerable distance; soon the flame is seen pouring in huge volume, but without smoke, from an enclosure about eight feet high, built of heavy logs of wood. At first sight we marvel that the rude altar, as it appears to be, is not consumed by the fire, but while wondering a bubbling noise is heard, each instant growing louder, until water commences to be thrown

up, *per saltum*, in a large fountain, which gradually attains the height of about forty feet, and then in the same manner retires. The fountain plays up every three minutes, and attains its maximum height only every sixth time. Originally the water reached over a hundred feet, but malicious persons have endeavored to choke up the well by throwing in stones and even large branches of trees, and have to some extent succeeded. The well was originally drilled for oil about six years ago, but the gas was struck and caught fire, and has been burning ever since. The search for oil being abandoned the owners endeavored to withdraw the tubing, but were only partially successful, so that water from surface springs now pours into the well to be subsequently thrown out in this intermittent manner. At night the mingling of the fire and water, making a fountain of prismatic colors, is surprisingly beautiful, grand, and awe-inspiring; surrounded as it is by the primeval forest, dark, gloomy, and oppressive in its stillness, the spectacle approaches the sublime, and gives the visitor the feeling of intrusion upon some weird and sacred scene.

Situated, as it is, on what is known as the gas-belt, almost anywhere around Kane an unlimited quantity of good illuminating gas can be obtained by simply boring for it. The town of Sheffield, about fifteen miles distant by rail, is lighted and heated entirely by natural gas which is also used as fuel for manufacturing purposes, the gas being thus used to run three large tanneries, two saw-mills and other similar establishments. The streets are also lighted with the natural gas, the supply of which is so abundant that the large lamps are allowed to burn continuously day and night, as they have done for about five years.

There are several oil wells also to be seen at Sheffield, some of which are flowing, others are being sunk along the line of the railroad. Bradford, a short distance above, is similarly lighted by natural gas, it is the centre of the new oil-field, and to those interested in the subject well repays a visit. There are no oil-wells directly in Kane but in its vicinity is the First Station of the United Pipe Line, which, with its large Worthington pumps, and large tanks, is an object of general interest. The large tanneries at Wilcox, eight and one half miles from Kane, are also worth seeing; while the numerous saw-mills and dams filled with logs, and the great piles of hemlock-bark are equally suggestive of mountain scenes and lumber-camps. Kane is south of Chatauqua Lake, and can be reached either from Maysville or Jamestown via Corry or Warren; it is about four hours distant from Erie by railroad, and about six from Niagara Falls. Visitors from the east come via the Philadelphia and Erie Railroad. This country is as yet not fully developed, the people are still civil to strangers, and the hotel charges moderate. The many advantages of Kane as a sanitarium have been appreciated by Professor Da Costa, who has been sending patients here with great benefit, for several years. Lately Dr. Weir Mitchell and others have become acquainted with its advantages and speak highly of it. There is an entire absence of malaria, and hay fever is unknown. Kane, as a place of mountain resort, has unquestionably a future before it, for it possesses advantages which are permanent and positive, and needs only to be better known in order to become widely popular. It possesses many of the merits of Colorado, and is much more accessible and convenient. W.

SEPTEMBER 15, 1881.

— Professor Frankland, of London, is reported to have lately analyzed a specimen of water taken from the sacred well of Mecca. This water is transported to all Mohammedan countries, and is greatly sought for by the faithful. The sample examined was

found extremely filthy and much infected by sewage, and is forcibly described as bottled cholera. It requires no effort of the imagination to realize the virtues of this water as a disseminator of disease, whatever its other merits may be.

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 8, 1881.

Deaths reported 2711 (no report from New Orleans): 1153 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 899, consumption 368, diarrhoeal diseases 353, diphtheria and croup 182, lung diseases 160, typhoid fever 134, small-pox 71, malarial fevers 63, scarlet fever 54, whooping-cough 16, measles nine, cerebro-spinal meningitis eight, puerperal fever six, erysipelas three. From *small-pox*, Chicago 41, Pittsburgh 18, Philadelphia seven, New York three, St. Louis and Cincinnati one. From *malarial fevers*, New York 16, Brooklyn 12, St. Louis eight, Baltimore six, Philadelphia five, Chicago and District of Columbia four, Cincinnati, New Haven, Charleston, and Nashville two. From *scarlet fever*, New York 25, Pittsburgh seven, Brooklyn six, Philadelphia, Baltimore, and Buffalo four, St. Louis three, Cincinnati one. From *whooping-cough*, New York seven, Chicago and Boston three, St. Louis two, Baltimore one. From *measles*, New York four, Boston two, Brooklyn and Chicago one. From *cerebro-spinal meningitis*, New York four, Chicago, Baltimore, New Bedford, and Haverhill one. From *puerperal fever*, New York, Philadelphia, Buffalo, Milwaukee, New Haven, and Lynn one. From *erysipelas*, New York two, Brooklyn one.

Two cases of small-pox were reported in Brooklyn, one in Boston, two in St. Louis, three in Cincinnati, 82 (of small-pox and varioloid) in Pittsburgh; typhoid fever 57, diphtheria 35, scarlet fever four in Boston; diphtheria eight, scarlet fever five, in Milwaukee. The epidemic of dysentery is subsiding in Buffalo.

In 39 cities and towns of Massachusetts, with a population of 1,039,961 (population of the State 1,783,086), the total death-rate

for the week was 21.01 against 21.98 and 22.99 for the previous two weeks.

For the week ending September 17th in 149 German cities and towns, with estimated populations of 7,806,793, the death-rate was 21.8. Deaths reported 3269; under five 1693: pulmonary consumption 368, diarrhoeal diseases 254, acute diseases of the respiratory organs 170, diphtheria and croup 135, scarlet fever 111, typhoid fever 74, whooping-cough 39, puerperal fever 18, measles and *rötheln* 14, small-pox (Benthen two, Aachen three), typhus fever (Königsberg, Grandenz) two. The death-rates ranged from 13.7 in Darmstadt to 34.8 in Posen; Königsberg 26.2; Breslau 27.1; Munich 33.5; Dresden 17.9; Berlin 22.4; Leipzig 17.8; Hamburg 19.2; Hanover 16.1; Bremen 17.8; Cologne 18.7; Frankfurt 17.9; Strasburg 23.1.

For the week ending September 24th in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 18.2. Deaths reported 2655: scarlet fever 110, diarrhoea 103, fever 73, whooping-cough 53, measles 39, small-pox (London 26) 28, diphtheria 21. The death-rates ranged from 15 in Bradford to 25.2 in Manchester; Leeds 15.1; Birmingham 15.2; Bristol 15.4; Sheffield 17.2; London 17.4; Liverpool 23.2; Manchester 25.2; Edinburgh 20.1; Glasgow 19.5; Dublin 22.8.

For the week ending September 24th in the 21 chief towns of Switzerland, population 479,934, there were 18 deaths from diarrhoeal diseases; acute diseases of respiratory organs 11, diphtheria and croup eight, typhoid fever seven, whooping-cough three, scarlet fever, measles one, small-pox one. The death-rates were, Geneva 10.6; Zurich 26.4; Basle 15.1; Berne 15.2.

The meteorological record for the two weeks ending October 8th, in Boston, was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM OCTOBER 1, 1881, TO OCTOBER 14, 1881.

EWES, CLARENCE, captain and assistant surgeon. Granted leave of absence for one year on surgeon's certificate of disability, with permission to go beyond sea. S. O. 220, C. S., A. G. O.

O'REILLY, R. M., captain and assistant surgeon. Granted leave of absence for six months from December 1, 1881, on surgeon's certificate of disability. S. O. 225, A. G. O., October 5, 1881.

HALL, JOHN D., captain and assistant surgeon. The leave of absence granted him in S. O. 141, August 4, 1881, Department of Dakota, is extended three months. S. O. 220, C. S., A. G. O.

MAYS, L. M., captain and assistant surgeon. Granted leave of absence for four months. S. O. 222, C. S., A. G. O.

CUNNINGHAM, T. A., captain and assistant surgeon. Granted leave of absence for one month on surgeon's certificate of disability. S. O. 102, Department of the South, September 29, 1881.

MURRAY, ROBERT, colonel and surgeon, medical director, Military Division of the Missouri. Granted leave of absence for two months. S. O. 100, Military Division of the Missouri, October 5, 1881.

JUGLIET, major and surgeon. Granted leave of absence for one month. S. O. 231, A. G. O., October 12, 1881.

WOODHULL, A. A., major and surgeon. Granted leave of absence for four months. S. O. 227, A. G. O., October 7, 1881.

KOLBORN, E. A., captain and assistant surgeon. Assigned to duty at Plattsburg Barracks, N. Y., as post surgeon. S. O. 180, Department of the East, October 7, 1881.

HARVEY, P. F., captain and assistant surgeon. Granted leave of absence for twenty-five days, to take effect on adjournment of the G. C. M., of which he is a member. S. O. 182, Department of Dakota, October 5, 1881.

COWDREY, S. G., captain and assistant surgeon. Granted leave of absence for four months. S. O. 228, A. G. O., October 8, 1881.

ARTEL, D. M., captain and assistant surgeon. Relieved from duty at Fort Supply, I. T., and assigned to duty at Fort Elliott, Texas. S. O. 201, Department of the Missouri, October 4, 1881.

ROBINSON, S. Q., first lieutenant and assistant surgeon. Granted leave of absence for four months. S. O. 228, C. S., A. G. O.

STRONG, N., first lieutenant and assistant surgeon. When relieved by Assistant Surgeon Shannon from duty at Fort Thornburgh, U. T., assigned to temporary duty with troops repairing road between Park City and Fort Thornburgh, U. T. S. O. 102, Department of the Platte, October 4, 1881.

MEMBERS of the profession will oblige Dr. Horatio R. Bigelow, 1502 Fourteenth Street, Washington, D. C., by reports of their cases of ovariotomy, on which subject he is preparing a paper.

BOOKS AND PAMPHLETS RECEIVED. — Report to the Illinois State Medical Society on Laryngeal Tumors. By E. Fletcher Ingalls, M. D. (Reprint.)

Quarterly Report of Medical Officers, United States Army, with their Stations and Duties. October 1, 1881.

Report of Section on Ophthalmology and Otology. By Samuel Theobald, M. D. (Reprint.)

Original Articles.

SAFEGUARDS IN PRIVATE OBSTETRICS.¹

BY J. P. REYNOLDS, M. D.

CHILD-BIRTH, viewed in its relation to the whole community, necessarily involves a certain percentage of death and disaster. The causes of danger are always at hand: overwork, starvation, sorrow, desertion, and anæmia come before, and hæmorrhage, convulsions, and insanity follow after. Disease, deformity, disproportion, malposition, and malpresentation put the child in peril. Careless or criminal neglect in the period immediately following delivery adds another element of danger. And no ordinary attention can save from these risks the class of pregnant women who supply and always will supply the material for hospital and dispensary practice.

Fortunately, results very much happier may legitimately be claimed for the private exercise of obstetrics. In cases of the latter class the profession enjoys and the community, from year to year, increasingly exacts, watchful oversight. Illustrations of this fact meet us on all sides. The prophylactic management of women approaching confinement has several times, within two or three years past, been exhaustively treated by English-speaking accoucheurs. We are weighing together the pros and the cons of a proposal that Listerism, so-called, be applied even to cases of labor. That time-honored practitioner whose refinement of modesty forbids him to look at a bulging perineum is fast disappearing from our ranks with his colleague, who in the practice of a lifetime never encountered anything wrong in obstetrics. The modern attendant is beginning to be held almost responsible for a lacerated cervix. He is expected to know, not to guess, the measure of the involution that takes place. He is held to blame if fetid lochia are not watched, or if creeping inflammation of the connective tissue escapes his notice.

Upon this subject, in its full extent, I do not propose to enter. I ask your attention to three unpretentious details in the duty of an accoucheur, upon which the safe conduct of his cases will, in my judgment, largely depend. These are, first, that he take an intelligent care of each patient during the six or eight weeks before delivery; that as a matter of obligation he make her during this period visits sufficiently frequent to render him familiar with the details of her bodily and mental condition. Next, that he *make sure, by extreme care and peremptory order* of being summoned to the patient when she has the first warning of approaching labor, go promptly to her, and from that moment take the full charge of her case. And lastly, when delivery is completed that he watch the management of the sick woman during two hours or an hour and a half, remaining in most instances at her side.

Not only are these points commonplace, they are even trivial. I am addressing honorable and upright professional men, who give every needed attention to obstetrics as to other parts of their work, who, if summoned to labor, avoid delay, and when the birth is completed do not leave their patients till they have all reasonable assurance that the time of danger has passed. And yet my effort is to emphasize more strongly these very habits, and to point out their extreme importance

and value in the care of women confined. For I suspect that medical men, in not a few instances, fail to recognize any duty to a case of obstetrics till notice of labor is given. To many practitioners the attendance upon births is an annoyance, a vexation, an interruption to their work, an interference with comfort, sleep, and eating, comparable to the worries of teething, vaccination, and nursery croup, except only that this is a trial immeasurably worse. The nurse "should know when not to send for them;" "ought to be capable of superintending the first stage of labor;" "must not summon the doctor till he can be of some use." The child born, the placenta delivered, no hæmorrhage showing itself, and the general condition of the patient being cheerful, the physician's duty to others presses upon him. The nurse is at hand to apply the bandage and to put the bed in order, as well as to wash the baby and dress it. He has endured most burdensome and fatiguing attendance, — he has a right to relief.

And yet, commonplace though these suggestions are, a conviction of their important bearing upon the safe conduct of obstetrics, which deepens with every year of my professional work, must be my excuse for bringing them very briefly before you to-night.

I need hardly justify my first recommendation by any elaborate arguments. It has been lately said with great force that the preparation of woman for labor exacts the use of very much the same methods which a man adopts in training for a foot race or a rowing match. Her strength is to be gotten up in every way for the great trial, and towards this end the positive efforts of her adviser may greatly help. He is not to judge his principal duty performed because he has searched the urine for albumen and casts; pallor, exhaustion, depression, mental worry, above all sleeplessness, ought to arouse his interest and command his most earnest and watchful care. In obstetrical communications the risk which attaches itself in labor to the woman seduced and abandoned has become classical, but such a statement still leaves unnoticed other cases of precisely similar import. The clergyman's wife who, in the eighth and ninth months, must sit up till the small hours to hear the reading of his sermons, the woman whose husband has been for weeks sleepless with the agony of impending bankruptcy, she whose daily life is made wretched with that thorn in the side, a merciless mother-in-law, or that other whose wrongs have robbed her home of all peace, these are equally the cases that invite puerperal insanity, eclampsia, and fatal hæmorrhage. By watchful, persistent tact to gain the clue to the unrest which his eye detects, to force home upon the mind and heart of thoughtless bystanders the knowledge that the woman who is on the eve of labor is doing a great work, that all those about her are in duty held to bow down to her, help her, and comfort her, that she is by the mere fact of her pregnancy made unfit either to edit an encyclopædia or to keep a hotel, becomes then a physician's obligation. Sleep must be made possible, and, in case of need, must be secured, week after week, by the steady, unremitting employment of suitable drugs. Let me say, in passing, that in many cases marked by persistent wakefulness, the good effects of a judicious use of chloral and the bromides are not limited to the production of sleep at night, but are felt throughout the nervous system and in the mental condition.

Nor is this all. To many a mother of troops of children, from whom the details of housekeeping, dress,

¹ Read before the Boston Obstetrical Society.

meals, discipline, steal all repose, the service of a physician who patiently, perseveringly, remorselessly, by daily visits, it may be, gets her under his thumb, and by degrees gains for her two weeks of bed and feeding before her confinement, is worth more for the avoidance of accidents in labor and for the prevention of puerperal disease than cart-loads of tonics and oceans of antiseptic injections. I do not forget that there exists, on the other hand, a class of self-indulgent, indolent women who need, even up to the moment of labor, to be roused to moderate though continued exercise and occupation, but these form among us an inconsiderable minority.

Of food during these weeks not much need in most instances be said. Excessive appetite sometimes needs restraint. Articles of diet outrageously difficult of digestion are never to be allowed just before the onset of labor. In cases in which there is good ground to expect eclampsia an exclusive milk diet not only affords a great guarantee of safety, but frequently extorts from the patient the warmest acknowledgment of comfort and relief.

Care of the rectum and bladder, truisms in all obstetrics, must never be forgotten. And I pay willing tribute to direct tonics, and especially to iron. The number of pregnant women who find help in it is very large.

My second point is that the patient, the husband, the nurse should be alike instructed that it is of the first importance for the best conduct of labor that the attendant be notified at the very earliest moment, so soon as the recurrence of two or three pains make the mother convinced that her labor is beginning. Promises to this end are readily given. It is no easy task to have them faithfully kept. Not only does the nurse ordinarily consult the doctor's case, or the husband hope that the accoucheur is not required till daylight, but the very woman herself shrinks from a hinting that the hour has come. And yet the physician's selfish interests, as well as his real comfort in his work, demand this quite as truly as does the welfare of the patient. If promptly called, after being made sure that everything that he may need is already in the room, and having convinced himself by a reasonable delay that there is no probable urgency, he may with the greatest peace of mind again and again absent himself for periods which he fixes definitely in advance during which all other important obligations are cleared away, his own personal preparations are made, and everything is arranged for the entire appropriation of his time to the new duty. Nowhere in life is it so true as in this work that the early bird gathers the grain. The breaking of a dam may sweep away every house in the valley, and sacrifice hundreds of lives, but there is always a moment when the whole risk lies in a trickle that a boy might check. Run through the whole gamut of obstetric emergencies, from a swollen anterior lip to a cranium hopelessly wedged in the bones of the pelvis, where can we find one that will not be found easy or difficult, just in proportion as the physician undertakes it in season or comes too late?

With what ease in the majority of cases will palpation at the beginning of labor detect the head in a pelvic presentation or in a transverse. With what comfort, at that moment, or even external version be accomplished providing the presenting part be still high in the pelvis and the membranes unbroken. In the simple

matter of diagnosis of position by vaginal examination contrast the confident assurance of the man who has steadily watched from the beginning the progress of the mechanism with the worry and uncertainty of him who finds under his hand a tumid and swollen scalp, and bones distorted and overriding. None of us receive without anxiety the summons to a woman in paroxysms of eclampsia, but were the habit which I am urging established in the profession, how much oftener would timely warnings come from localized headaches during labor, from unusual restlessness and agitation, from pains aimless and ineffective, putting an observant physician on the alert long before the slightest choreic twitching of an eyelid proclaims that danger is at hand. The same necessity, that the case be watched from its very outset, applies with the greatest significance to the timely use of forceps, of which so much has lately been said, and said, too, with such wonderful force. It is largely to delayed attendance that the worst dangers are due. With many a funis long prolapsed, an arm or foot precident by the side of the head, a breach hopelessly wedged, early watching would have substituted for all the difficulty and peril the chance of easy relief. And without such neglect who would know the fearful picture of a uterus, after redoubled hopeless, overpowering efforts, helplessly bound down in tetanic rigidity over some impossible presentation.

Lastly, there are few occasions in which the personal presence and control of a physician are of greater value than in the lying-in room during the period following delivery. Women are in some occasional instances apparently confined with little or no nervous shock. Parturition deserves with these patients little more serious regard than defecation. They approach it with something of the unconcern with which the commercial traveler enters upon his fifty-second Atlantic passage. But these are rare exceptions. Under all the cheerfulness and even gayety of the newly-delivered mother, amidst the hurry and bustle of the surroundings, how many times has one occasion to hear at last the sigh of relief and watch the comfortable settling down to rest, when noise and light have gone, when the nurse and the baby have been dismissed, and the physician, his hand watching patiently the uterine contraction, mounts guard till the hour of imminent risks has gone by. The shock of labor, the exhaustion of nervous power which that process brings, is only too familiar to us in severe cases. But the fact that similar symptoms, less only in degree, accompany nearly every labor, is not always recognized. And yet, attentively watched, there are few patients who do not betray it. The real restorative for this effect of labor is rest, and, if possible, sleep. In extreme cases we acknowledge this in our resort to opium, used not infrequently as the best of stimulants, but ordinarily bringing with that first effect the readiness to sleep. Even in ordinary childbirth every one of nature's processes is helped by sleep. It is surprising to observe how little many advisers appreciate this. I have known a primipara, exhausted by hard confinement, to be conscientiously roused by her nurse during every time that she dropped asleep during twenty-four hours because "sleep after confinement is so dangerous," severe puerperal insanity supervening three weeks later; and Cazeaux, though hesitatingly authorizing a nap after delivery, is careful to add that it is nevertheless of the utmost moment that throughout all this sleep the condition of the uterus should be constantly watched by an experienced attendant. The

repose enjoined should be absolute. Nothing so favors the safe contraction of a well-emptied uterus as deep and tranquil sleep. In not a few instances, when the uterus has remained for some considerable time of small size and well contracted during the period of enforced quiet, the preparation of the bed, the application of a bandage, some change of position, however carefully conducted, will cause it suddenly to double its size and to attain a marked elevation and prominence. So that in cases of hemorrhage I have heartily approved that advice, which has neglected for hours every one of these important attentions, lest the mere fact of disturbing the patient should involve the loss of all that has thus far been gained.

Obviously what has been said is open to the criticism that life is short, and that care that is not ordinarily essential should not be required. Shall a man always stay at home because in any walk out a coping stone may fall on his head and kill him? No, indeed! and yet in the matter under consideration this argument may be pressed too far. The few additional hours which careful preliminary watching, acceptance of responsibility and attendance from the first warning of labor, waiting a somewhat longer period after the birth, take from the time of the general practitioner are few in number with most of us, and ought to be little weighed, in view of the great additional safety of the patient. However we may dream of overwhelming obstetric engagements the physicians are surprisingly few in any country who attend two hundred labors a year. Few men in middle life count as a rule thirty cases in a twelvemonth. No words of mine are needed to portray the stake which families under our care have in the prevention of danger in childbirth. To see taken away from hearth and home the one being in whose safety more than in that of any other the happiness of all rests, to be responsible in any degree for a breach that is never filled, is bitter work. Gladly should we bend all our energies, spare no time, count trouble light to prevent that.

A CASE OF PYLEPHLEBITIS.¹

BY J. L. HILDRETH, M. D.

MRS. P., age forty-four, tall, large, and fleshy, was first seen by me January 26th, after having had a severe chill. Three days before she had been to Boston in a snow-storm, and got very tired and cold. For three weeks before she had not been well, having frequently, after taking food, nausea and sometimes vomiting; she also had spoken of chilly sensations and of some pain in the bowels; her friends had remarked that she did not look well; her sleep had been poor, and in the morning she was not rested; headache and loss of appetite she had complained of. The exposure in the snow-storm seemed to hasten the sickness that was coming upon her. At the time of my first visit I obtained the following history:—

She was born in Massachusetts, always had been strong and robust, and generally during the past three years had weighed about one hundred and ninety-five pounds. She was married at twenty, had borne two children, both boys, the youngest twenty-one. Since her last confinement had scarcely been sick. Among

her friends she had been a wonder, never complaining of aches or pains, and in every way had seemed so well and strong. When first seen the chill had passed off, and she was vomiting, having severe pain at the pit of the stomach, and loose discharges from the bowels, with intense headache; pulse 121, temperature 103.2° F. She was so fleshy that any critical examination of the abdomen was impossible; pressure over the epigastric region was painful, and over the whole bowels there was some tenderness. Morphia and mint-water was given, and hot fomentations applied over the stomach and bowels. In the evening pulse 136, temperature 101° F.; headache severe; vomiting only partly controlled; pain at pit of stomach had not been relieved; the general appearance was of a person suffering from some severe malady. The morphia was ordered to be increased, and twelve grains quinine to be given in divided doses as soon as the stomach would retain it.

January 27th, second day of her sickness, recovered from the first chill; passed a comfortable night by taking two grains morphia; quinine had been given and retained; slept four hours, and had only one loose discharge; headache better; pulse 126, temperature 104.4° F.; pain at pit of the stomach and in the head, the only pain or discomfort complained of. In the evening was more comfortable; less pain; had slept some, and there had been no vomiting or passages from the bowels; pulse 118, temperature 104.8° F.

January 28th, third day. About midnight had a chill, but not severe; slept but little; after the chill great thirst; some vomiting, and one large, loose discharge from the bowels; pulse 136, temperature 104.6° F.; still complains of the pain at the pit of the stomach, and says it has extended to either side. In the evening pulse 140, temperature 105° F.; very restless; great pain; some nausea; takes little but hot brandy and soda water, milk and lime-water, and pounded ice; quinine and morphia continued.

January 29th, fourth day. More comfortable in the morning; pulse 130, temperature 103.1° F.; slept about three hours; takes the milk and brandy freely; no vomiting or diarrhea; no headache, but is conscious of a pain at the pit of the stomach, and flinches at slightest pressure over any part of abdomen; bowels considerably distended; skin and conjunctiva slightly tinged with yellow. In the evening less pain; pulse 116, temperature 102.2° F.; taken less morphia by one half.

January 30th, fifth day. Very comfortable in the morning; decidedly jaundiced; no nausea or vomiting, and is able to change her position considerable; pulse 108, temperature 101.4° F. In the evening pulse 102, temperature 101.2° F.

January 31st, sixth day. In the morning pulse 108, temperature 101.1° F.; slept poorly; great deal of headache and pain at pit of stomach; about eleven in forenoon had another severe chill, followed by profuse perspiration and weakness, so that brandy and soda water were given in large quantities. In the evening pulse 106, temperature 104.6° F.; intense thirst with considerable nausea and occasional vomiting.

During the three days following this third chill she remained about the same, pulse varying from 120 to 130, and temperature from 103° to 104.5° F.; there was but little nausea, and large quantities of milk and brandy and soda water were taken, with morphia enough to control the pain; quinine was given, about sixteen grains a day, in anticipation of another chill; jaundice nearly disappeared.

¹ Read before the Boston Society for Medical Observation, May 16, 1881.

February 4th, tenth day. In the morning another chill, but less severe than either of the three that had preceded. In the evening comfortable; pulse 122, temperature 104.1° F.; complains of pain extending all across the body from right to left hypochondrium, thinks it is worse in right side; unable to make any careful examination of the part on account of the pain and great tenderness upon pressure; decubitus that upon back, and can scarcely be moved except to be raised straight up.

February 5th, eleventh day. Passed a comfortable night; pulse 102, temperature 100.1° F. She says it is the most comfortable day since the sickness began. The tenderness in right side and across the stomach to left side nearly gone; has some appetite, and wants to be dressed and sitting up, and to have the same food as the family.

For the three days following there was little change in her symptoms; some pain and tenderness remained at the pit of the stomach and in either side, but she ate well, slept a good deal, and took ordinary food with considerable relish. The pulse and temperature remained about the same; quinine and opiates given in much smaller doses.

February 9th, fifteenth day. Another slight chill in the evening; two hours afterwards pulse 128, temperature 103° F.

February 10th, sixteenth day. Another chill, but not severe.

February 11th, seventeenth day. Chilly sensations, not amounting to a decided rigor; at this time she began to complain of pain through the whole of the left chest; had a slight cough, and said a full breath gave distress from the armpit to crest of ileum; decubitus was altogether up left side, and she complained of so much soreness and tenderness that for three days she was hardly moved; there was considerable dry cough and shortness of breath with slightest exertion; temperature was nearly normal in the morning, but generally 102° to 103° F. in the evening, with profuse sweating whenever she fell asleep.

February 11th, twentieth day. Was able to raise her up sufficiently to examine the chest; the lower left back was dull, respiration absent, and vocal fremitus marked.

From this time till February 20th the cough and dyspnoea increased; there was increased soreness over the whole of the left side; appetite poor; some vomiting, and profuse perspiration when asleep.

February 20th, twenty-sixth day. The dyspnoea increased so much that, with the assistance of Dr. Stevens, I aspirated from the left chest twenty ounces of bloody pus, with an odor intensely fetid. The removal of this fluid from the chest gave great relief. Dyspnoea afterwards was slight, and cough nearly absent. The appetite returned, and she was able to be dressed and sit up nearly an hour each day, but this temporary improvement lasted only a few days, the dyspnoea and cough soon came back, sweating was profuse, sleep fitful and disturbed, pain and soreness over whole chest greatly increased, and March 5th I again aspirated, removing only about twelve ounces of the same fetid pus mixed with blood. During the interval of time between the first and second aspiration there was a great deal of sweating, so much at times that the nurse was obliged to be occupied nearly the whole time wiping the face and hands and arms and limbs. Whenever she slept the perspiration would run down

the face so as to wake her up. The pulse varied from 90 to 108, but the temperature was generally at normal or a half or one and a half degrees below. She took nourishment well, bowels fairly regular, and nearly every day was sitting up from fifteen minutes to an hour.

From this time to March 10th, which was the forty-third day of her sickness, there was little change except an increase in the dyspnoea.

Dr. Ellis saw her then, and a permanent opening was made in the left side below and about a hand's breadth behind the nipple; twenty ounces of pus of the same general character as that obtained by the first aspiration was removed. Following this there was no particular change in the symptoms except that she grew weaker, and death took place March 19th, the fifty-second day from the first chill.

Autopsy. Body that of a woman about forty-five years of age, rather large and fat. The skin has a slightly yellowish tinge. Right side of heart moderately full of blood, left side contains less blood; valves everywhere perfect; interior of this organ smooth, and everywhere of the same color; muscular substance is softer than usual, and pale. Right lung fills the cavity of its side of the chest, and is nowhere adherent, dependent portions of a dark-red color; it is everywhere crepitant, and apparently healthy. The left lung is bound to the side by a fibrous band running from front to back, about in the centre of the lung, dividing the pleural cavity in two nearly equal parts; the upper cavity is smooth and glistening; the part of the lung in the cavity is healthy; the lower cavity is lined with a rough, ragged, and dirty deposit, it contains about a pint of dirty pus which is inodorous. There is an opening into the cavity through the walls of the chest, between the eight and ninth ribs, that readily admits the finger.

Spleen a little larger than usual, and quite firm.

Kidneys larger than usual, and have a swollen look, capsule slightly adherent, cortical portion thicker than usual and much paler, the medullary, the whole organ is a little soft.

Intestines, stomach, and mesentery glands healthy.

Liver enlarged, pale, and soft. The acini can be readily made out, the cut surface is generally of a grayish color, with darker spots about the central vein, giving it a finely marbled appearance; on the upper surface a rounded elevation, about the size of a filbert; this opened is seen to be a collection of pus; the base of this cavity, about a half inch below the surface of the liver; there is no hardness about this point. The portal vein is apparently of a normal size and thickness, the part of it below the liver contains a mixture of pus and blood, the part in the liver in all its branches contains nothing but a creamy-yellow pus.

IMPORTANT POINTS.

The important points in the case seem to be these:—

A woman, apparently in perfect health, is about three weeks suffering from nausea after taking food, with occasional vomiting, and seems generally unwell. Three days after exposure has a severe chill with severe pain at the pit of the stomach, nausea, vomiting, and diarrhoea, followed by severe fever and great prostration. In a few days another chill with the pain extending to right side, in a few days more it extends to left side, and during the whole of the remaining sickness, pain, soreness, and tenderness upon pressure is

never absent, extending from the right to the left hypochondrium. About the sixth day jaundice makes its appearance, but gradually disappears, and is nearly gone at the end of the fifteenth day. Pain in the left side came on about the twenty-fourth day, after a severe chill; fluid was present so as to cause dyspnea and require aspiration in seven days, a permanent opening about the forty-third. Sweating was marked during the fourth and fifth weeks with a temperature, as indicated by the thermometer, from one half to one and a half degrees below normal considerable of the time. The last two weeks there were chilly sensations most of the day, but not a distinct chill.

The autopsy showed no trouble in the abdominal cavity which could have been the starting-point of the inflammation in the portal veins. The use of quinine had no effect in controlling the chills.

Urine. The urine was examined several times by Professor Wood, each time with nearly the same result. It always contained some albumen, a few granular and blood casts, urates in great quantity, its color was of a deep red, evidently concentrated, and generally had a peculiar odor, perhaps it might be called strongly urinous. I thought the fetid pus from the side resembled it somewhat. Professor Wood suggested acute parenchymatous nephritis similar to that dependent upon blood-poisoning.

RECENT PROGRESS IN MENTAL DISEASE.

BY CHARLES F. FOLSOM, M. D.

Lecturer on Mental Diseases, Harvard Medical School.

IN the pathology of mental disease, although careful investigations are yearly adding new facts and confirming previous observations that there are always well-marked and definite changes in the brain in insanity of which paralysis is one of the symptoms and in chronic dementia, and that generally mental disease is associated with recognizable morbid conditions, which become more manifest the longer the duration of the disease, it must still be said that, except in dementia and paralysis, we know very little of the pathological conditions of the brain *giving rise to* insanity beyond the fact that they probably are chiefly cortical and diffuse rather than local.¹ In doubtful cases, therefore, there are no purely physical symptoms (pulse, temperature, etc.), which furnish strong presumptive proof of that loss of self-control which constitutes the chief distinguishing feature of insanity.

In the classification of mental diseases, the disposition to place etiology, symptomatology, and metaphysical distinctions on a lower footing than pathology and clinical history is more and more manifest—a subject which is considered at some length, with a comparison of the systems of classification, in the JOURNAL of July 22, 1880.

In the medical jurisprudence of insanity recent cases indicate that the strictly medical-expert theory is gaining strength, especially in this country, to the manifest benefit of the criminal class, but with a more than possible danger to society, whose interest naturally lies in the direction of maintaining the highest standard of responsibility consistent with justice, safety, and humanity.

¹ For a fuller discussion of this point see the JOURNAL, July 15, 1880.

The chief advances of late years have been due primarily to efforts for better treatment—in this country directed toward following the Scotch and English methods of less restriction, and in acceding to the popular demand for more elegant hospitals, and to the wishes of the superintendents for greater ease in administration. It we may judge by the last edition of Dr. Kirkbride's book,² our changes in asylum construction during the last twenty-five years, from the patients' point of view, consist in better ventilation, heating, and opportunity for classification, and more room, air, light, cheerfulness, and means for amusement. The same statements hold good, to a less degree, however, of France.

There is great misapprehension in the United States as to what has actually been done elsewhere in giving excessive liberty to the insane, arising from the fact that people who have had very few opportunities for observation and experience, and who generalize somewhat hastily from scanty knowledge, give their conclusions to the public through the daily press with a self-confidence that begets in the minds of the community unjust condemnation of institutions, in regard to which they hear little but disparagement, and because exceptional authorities, somewhat dogmatic even if of advanced views, who advise very wide departures from the common practice, are quoted (not always correctly) as if they so fully represented all the intelligent medical opinion on insanity that those disagreeing with them were simply ignorant or knaves. As a matter of course the friends of other asylums, here and abroad, in self-defense, go to the opposite extreme and exaggerate correspondingly the comparative merits of their own systems, while the community, having no government lunacy commission to which it can refer for impartial information, being naturally distrustful of public officers, and having no means of testing for itself the truth or falsity of charges against them, believes what is asserted the most loudly.

After some careful study of this matter in Europe in 1873, 1874, 1875, 1878, and 1880, I think I am safe in saying that the public asylums of Massachusetts, with which I am most familiar in this country, are in all ways superior to the vast majority of those in France except in the matter of scientific study and experiment, while mechanical restraint is so generally adhered to throughout the new republic by the best authorities, with only here and there a rare exception, that at a recent meeting of the leading psychological society in Paris, after full discussion of the subject during four sessions, all but one of the members present were strongly in favor of mechanical restraint in the treatment of the insane. The Germans do not provide their patients so many personal comforts nor such pleasant hospitals as we give ours, but surpass all other nations in scientific research, while they are rapidly developing the non-restraint system, in some places even more absolutely than is done anywhere in England or Scotland.

The readers of the JOURNAL are already, in a general way, acquainted with the vast advances which have been made in some European asylums, more particularly in Scotland, but it is only fair to say that our attention has been drawn chiefly to hospitals which are landmarks even in their own country, and that it

² On the Construction, Organization, and Management of Hospitals for the Insane. By Thomas S. Kirkbride, M. D., LL. D. Philadelphia. 1880.

is still possible to pass a long time visiting many asylums, even in much-praised England, without any feeling but disappointment that they are not better than they are, nor so good as ours,—for our patients at least. I feel quite sure, as did Griesinger, after a most painstaking investigation, personally, in various countries, that there are decided peculiarities of climate and race, and social differences that will always prevent the adoption of any universal plan of treating insanity everywhere by a uniform rule, although I believe that Americans, Germans, Irish, French, Scotch, and English are none so perfect in this matter that they cannot study to advantage the work of the others.

In Germany an asylum for two hundred patients was finished a few years ago at Marburg in accordance with Dr. Meyer's plan¹ of several (eight in this case) entirely disconnected buildings, containing from ten to forty patients each, with open grounds, out-of-door occupation, no high-fenced airing courts nor mechanical restraint, and with the light portion of the window-sashes made of wrought iron in all but the quiet wards so as to avoid the appearance of bars. At my latest information two other asylums were building upon the same plan, and in about a dozen there was absolute disuse of mechanical restraint. Professor Westphal's wards in Berlin, with which ours have been invidiously compared, having one attendant to each three patients, or about three times as many as in our State institutions. In Belgium the vast majority of the insane are treated in asylums similar to those of other countries with a rather liberal use of restraint, several hundred being let out to peasants in Ghel to work about the farms, with now and then an ankle-chain, until very lately at least, to prevent running away or active violence, and being sent to an ordinary asylum so soon as they become unmanageable under the peasant's discipline, a method not yet followed in any other country.

Recent Scotch and English advances have been so fully described in the JOURNAL² and in the Seventh³ and Tenth⁴ Annual Reports of the State Board of Health of Massachusetts, that it is not necessary to more than briefly allude to them here. Conolly never took the position that mechanical restraint should *never* be used in the treatment of the insane, but maintained that the very rare cases where its use is desirable occur so seldom that it is possible to manage large asylums for years without once resorting to it. With very few exceptions, this was the position of English superintendents twenty-five years ago⁵ and remains the same now, as it is also in Scotland, the only real change that has taken place being, according to my observation, the abandonment on both sides of the extreme views that were advocated by a few persons in the heat of the debate on Conolly's reform, and a gradual decrease in practice of the cases in which mechanical restraint would be considered the best means of treatment. Neither Dr. Bucknill's utter discarding of mechanical

restraint under all circumstances nor, at the other extreme, Dr. Shepard's use of it in eight individuals at Colney Hatch in the course of a year, with an average daily number of a little over one thousand patients, represents any considerable body of English or Scotch medical superintendents. In the best asylums in England and Scotland not far from three fourths of the inmates are occupied, many of them profitably, some hardly being able to do more than trundle a wheel-barrow under direction: in others very few patients work, and there are all possible intermediate degrees of practice. Those amusements are encouraged, and to a greater or less extent carried out, in which the insane can themselves take part. Mechanical restraint is so rarely resorted to that it has been said, and I have no doubt with truth, that it is possible to go the whole round of English or Scotch asylums without seeing any more of it than occasionally soft mittens, or long sleeves closed at the ends which simply prevent the free use of the fingers, leaving the arms free. I have never seen any other forms in frequent visits to many of their institutions. The large panes of plate glass, and the unbarred wooden sashes first used at Rainhill, now not uncommon in England and Scotland, have the great advantage that each ward, or even room, can be managed to suit the needs of its occupants, the windows may be precisely like those of an ordinary house, they may be arranged so as to open just wide enough not to allow the passage out of the human body, or they may be protected in cases of violence by a shutter which is so concealed as ordinarily to hardly indicate its presence. It is seldom used, however, and I found on the day of my visit to Woodilee, last year, that with about five hundred patients, only sixteen had their windows protected during the previous night, and none at the time of my inspection. These shutters, although so little used, are less unsightly and prison-like than those, some of which are quite generally found closed even in the daytime, in our own State. Dr. Tuke's open-door system⁶ has been maintained at Cupar by his successors, Dr. Fraser and Dr. Brown; it has been adopted in his own private asylum, and Dr. Rutherford has extended it to every ward in his new asylum for the insane of one half the City of Glasgow, the following description of which, in his own words, seems to me quite just. Some of the attendants even have no keys, but the doors of course are always locked at night.

"A year has again passed without the occurrence of any serious accident to patients or attendants; indeed, no untoward event of any kind has occurred to disturb the harmony of the institution. . . . With three hundred and eighty-two acres of land surrounding the asylum, there can be no lack of means of employment for the patients, and of such a kind as cannot fail to still further develop those principles of treatment in which this asylum has taken a decided lead. . . .

"The nature of the work necessarily varies with the season of the year. It consists of the cultivation of the farm and garden, together with ordinary estate work, such as road-making, planting, fencing, draining, quarrying, building, etc. In quarrying, building, and conveying the materials, about forty men and their attendants have been regularly employed during the past two years. . . .

"Besides the one hundred and fifty men who work out of doors under the care of ordinary attendants, and the twelve able-bodied men who act as house cleaners

⁵ The Tenth Annual Report of the Lunacy Commission of England, pp. 123 to 209, in which the opening of one hundred and eighty-nine new, or altered, or enlarged, or public and private asylums, are given, and the present state of the question is fully discussed before the British Medical Association, as reported by Dr. T. L. Rogers in the *Journal of Mental Science*, October, 1874.

⁶ See the JOURNAL, August 12, 1875.

about thirty are employed as tailors, upholsterers, store-keepers, shoemakers, bakers, plumbers, blacksmiths, painters, joiners, engineers, and stokers, under skilled artisans, who are required primarily for necessary tradesmen's work in connection with the institution, and are attendants only in the sense that they employ the patients of their respective trades. . . .

"This full employment of the patients renders it possible to give greatly extended liberty, and to do away with all remaining forms of mechanical or chemical restraint, such as walled courts, locked doors, stimulants, narcotics, and sedatives. No airing court or inclosed space of a like nature has ever existed at this asylum. The doors of the wards open directly into the grounds, and the whole estate is the patients' exercising ground. From fuller employment and increased liberty, with their accompanying diminished manifestation of insane acts, there proceeds a greater capacity for self-control. On this principle, all the doors of this asylum were originally constructed to open with ordinary handles and without a key. An unfortunate accident occurred shortly after the opening, due to a patient escaping, not through a door, but through a window, and it was considered prudent to alter those doors opening to the grounds by removing the inside handle. Two years ago these locks were restored to their original condition, and the asylum has, as your committee are aware, since been conducted with open doors, with fewer accidents, a smaller proportion of attendants, and with fewer attempts at escape than formerly. It is with pleasure that I am able to say, that many Scotch asylums are now conducted largely on the open-door system, and some of them very largely; but Woodilee is, so far as I am aware, the only public asylum which is conducted *entirely* on the open-door system, for in it there is not even a closed ward, where so-called refractory patients are confined."

Of course it is necessary, under Dr. Rutherford's method, to have the patients kept — in herds, I was inclined to say — under the direct eye and control of the attendants, perhaps more than would be generally tolerated among Americans, who, sane or insane, are so sensitive to constant supervision as to be almost intolerant of it, and who have not all yet fully learned the difference between self-will and independence or license and liberty. As a matter of fact, the open doors of the "open-door system" mean freedom to go in and out to one fourth, or at most one third, of the patients. The others are under such close watch and direction of attendants that even in Scotland most of the superintendents consider their liberty to be quite as much restricted as by the locked doors, and regard the open doors as more useful for certain selected patients than as a system for all. The enlarged liberty now given to the insane in many asylums of Great Britain consists in substituting the watchfulness of trained attendants, with the educated self-control of the patients, for high fences and indoor seclusion, and contrary to what seems the prevalent opinion here, not in allowing irresponsible lunatics to wander about the country on parole. Dr. Sibbald's abandonment of high-fenced airing courts has been followed in Scotland universally, and to a less extent in England. In both countries fences five or six feet high are usually considered quite necessary. The fifteen hundred pauper insane boarded out in families¹ under the Lunacy Commission are

in the main well cared for, and with constant supervision the plan is a thorough success, now that the difficulties of securing good attention and of preventing a certain amount of illegitimate births have been obviated. Under the advice of Mr. Mould,² of Cheadle, the medical superintendent of one of the asylums near Birmingham, the trustees have recently purchased or hired several dwelling-houses within an area of two miles of the main building, by which means it is practicable to classify and treat the patients under much more favorable conditions than formerly. To a less degree also elsewhere in England and in Scotland, pleasant houses are used, especially in the summer, for the entertainment, or as a seaside resort, of parties of patients one after another.

That an enormous improvement has taken place in the condition and behavior of the insane from these steps goes without saying. The change from 1874 to 1880 in Dr. Clouston's wards at Morningside, for example, would have seemed to me almost incredible if I had not myself seen it. The great change in Scotland is due largely to the wisdom of Sir James Coxe and Dr. Arthur Mitchell, as shown in the policy³ they inaugurated in the lunacy commission of working with the utmost harmony and courtesy *with* the asylum officers rather than against them; but I fancy that still more has come from the genius of such medical superintendents as Clouston, Sibbald, Tuke, and Rutherford, even if their example has not always been followed, from the wide experience of the medical staff generally, and from the confidence of the community that the asylums will keep ahead of its just demands rather than behind them.

As already intimated, the men whose asylums are held up to us for immediate imitation are leaders in their own countries, and it is still doubtful how far their examples will be followed even at home, but Marburg, Gheel, Rainhill, Morningside, Cnpar, Woodilee, and Cheadle have important lessons, that the usual restrictions upon the lives of the insane can be very much reduced to their great benefit and with perfect safety, — a matter which is of no small importance to those who have known the misery of needlessly rigid confinement. In our country, where employment is as a rule abundant, attendants leave the asylums and seek less confining work if required to give as close attention to patients as the open system demands, and still it is almost impossible in most of our asylums to secure attendants enough, even without raising our standard of requirements. Where, too, patients require so many attentions in the way of serving food, care of clothing, etc., as ours, we need a larger proportion of attendants than in European pauper asylums, where a shirt is a shirt if only of the right size. Our rigid winters and intensely hot summers absolutely forbid for a considerable portion of the year that out-door exercise and employment which are thought in England essential to the success of the non-restraint system, and the demoralization created by confinement in-doors during January, February, and March is not easily counteracted before the burning heat of July and August excites it again. Our patients are of so many social grades

² See the Presidential Address delivered at the annual meeting of the British Medico-Psychological Society, by George W. Mould, M. R. C. S., in the *Journal of Medical Sciences*, October, 1880.

³ There is no better description of the workings of the Scotch Lunacy Commission than Dr. Arthur Mitchell's testimony, pages 461-490 of the Report from the Select Committee on Lunacy Law, London, 1877.

¹ See the recent Annual Reports of the Lunacy Commission of Scotland, especially Dr. Fraser's and Dr. Lawson's Reports.

that classification to avoid want of harmony is extremely difficult; they demand more than in Great Britain that the noisy and violent be secured from annoying or injuring the quiet; they are far less willing to be obedient to authority of physicians, and especially of attendants; they require better food, nicer clothing, more little attentions; fewer of them are accustomed to manual labor or willing to "lower themselves" to it, or to "work for the State," to which their relatives and friends also often object, and a *larger proportion* of them are of the worst type of insanity, although our worst type is no worse than the worst of Scotland and England.

When I first visited Europe, in 1873, I had seen in this country from six to eight per cent. of patients in mechanical restraint; I knew cases where the camisole had been continued months or even years after its use had ceased to be necessary or best, even on the ground of its original adoption. In Professor Westphal's wards in Berlin, where mechanical restraint is never used, I saw a vigorous, well-developed young girl of about twenty held in bed by three strong young students, during a maniacal paroxysm, in a manner which seemed to me indelicate and on other grounds objectionable, but with the merit that it was discontinued immediately it was not needed. Coming back to the United States I found in one hospital six women wearing strong camisoles and bound in chairs, the feet of three not resting upon the floor or anything else; in another, out of three hundred patients, six were in iron handcuffs, and three were fastened by a few iron links to the wall or to chairs in which they were put. Visiting England again, I found that what seemed to me dangerous doses of morphine, hyoseyamine, and digitalis were not seldom used in place of mechanical restraint, although with many of their best men that I could mention such was not the case, less drugs, if anything, being used than here. I thought there was in some asylums indication of violence which might have been easily prevented by mechanical restraint. Certainly, an occasional patient running about half-naked and shivering in a temperature of 60° F., or exhausted to the point of inability to fairly stand, or clothed by day and covered at night with thick duck quilted almost to virtual indestructibility, or kept several hours together in a cold bath, would suggest to advocates of the judicious use of mechanical restraint some justification of their method of treatment. After my return I found an insane man who had worn iron handcuffs day and night for several years, and another with iron handcuffs fastened to an iron chain around his waist, which were removed twice a week for a change of the clothing that he wore day and night. All these cases of exercise of mechanical restraint which I have mentioned are, in my experience, common enough in the treatment of the troublesome insane in almshouses, and very exceptional in the asylums of this country, as extreme drugging is said to be in England; but still it seemed to me that a system capable of such abuse, and indicating what, from my stand-point, was an entirely wrong conception of insanity, to say nothing of those institutions where mechanical restraint is habitually used by the attendants and not by the medical officers, should be abandoned; and yet I remember that when in Germany and England there appeared to be so many serious objections to the dogmatic adherence to "non-restraint" that the *judicious use* as a *medical prescription* in rare cases of the least objec-

tionable forms of mechanical restraint seemed on the whole best. After all, such matters depend more upon the manner of the observance of the rule than upon the rule itself to an extent which is not always indicated in printed reports or revealed to any other than expert visitors. The advocates of non-restraint admit that there are cases where individual patients might have been better treated with mechanical restraint, but maintain that the moral effect on the others is better for its absolute, or nearly absolute, disuse. They show, too, that the system of non-restraint has been an educational one upon the medical staff and attendants, by requiring them to devise substitutes for mechanical restraint in occupation, diversion, and careful medical treatment. So far they are certainly right, and with all the faults of their system it seems to me clearly better than that generally, but not universally, practiced in the United States.

We have passed the time when theory and speculation are most useful in treating this whole question, and must now await the teachings of experience. The asylums of this country and France and, to a less extent, those of Germany and parts of England can do much more than they are now doing in enlarging the freedom of the insane; we all can add to their means of comfort and happiness, and possibly raise the percentage of recoveries. In such climates as ours we should be obliged to exercise our utmost ingenuity to devise in-door occupation for the worst parts of the year, and with our people we would require more attendants. Those of our hospitals needing more and better-trained physicians will supply that want with the general elevation of the standard of medical education in our colleges and universities.

Whether or not we go as far as Dr. Clouston or Dr. Rutherford would advise, we cannot proceed far in increasing the liberties of our insane without educating the community to look upon mental disorder as a disease which is to be treated upon the principles of medical science and common sense, and to regard insane persons as pretty much like other people, with narrower powers of self-guidance and self-control, as they now persistently refuse to do. People must learn that it is wrong, as well as unwise, to lie to them, and the abominably wicked deception pretty uniformly practiced towards them outside of asylums must be given up for fair dealing. The insane must believe that they will be treated at least honestly, and when sent to an asylum committed in an honorable, straightforward manner, and not entrapped by underhand devices. Attendants must become accustomed to the new order of things. The doctors have before them the long, tedious work of overcoming the natural suspicion of those patients who feel that they have been cheated by their friends and caught in the hospital trap, of organizing a vast work with insufficient means in the face of unjust popular distrust, and of attempting to educate into some sort of habits of self-help the old asylum boarders, in whom years of mental and physical inactivity have produced corresponding helplessness and loss of power of self-restraint, to the demoralization of those newly committed, — all this, beside living and working among people many of whom have lost comparatively little in intellectual capacity while so given over to the violence of evil passions and impulses as to make them, not seldom, in the highest degree dangerous and even homicidal unless under proper control, and all of whom have been sent to the

asylum because they were beyond the capacity of treatment outside. It lies in the power of the community and of the State to either help or hinder the solution of this difficult problem.

The duty of the State in this matter is one which is engaging more and more the public attention each year, and the more any country has already done for the protection of its insane, the higher is its standard raised for future work. In England, during the past few years, there has been a strong movement for better safeguards against improper commitments to insane asylums, and for "an efficient and sufficient inspection of asylums such as this country has never yet enjoyed."¹ An intense opposition has arisen, too, in the medical profession and outside of it, to the asylums which are not directly controlled by the State, on the ground that "the business of the boarding-house" conflicts with the best interests of the patients,² a danger far less in the United States than in Europe, but one which can be fully provided for in either country by efficient State inspection. The feeling in this country, at least, is very decided that private asylums are not only useful but very much needed, and certainly there is no more danger that the superintendents of them will not adopt the best methods for the early cure of their patients than that other professional men will fail to see that their true interest lies in doing well and speedily whatever they undertake to do.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

CASES UNDER THE CARE OF DR. R. T. EDES.

PROBABLE SECONDARY DEGENERATION OF LATERAL COLUMNS OF CORD. EXAGGERATED REFLEXES.

CASE I. Alexander D., aged sixty-one, laborer. During the last year has had pain in left hip, knee, and outer side of foot. Slight headache referred to right frontal and right occipital region.

Refers to some previous occasion when he had a sudden attack of pain but says he was not paralyzed. (It is difficult to disentangle this story from that about the cataracts which were operated upon four years ago.) The want of clearness is, however, so far as one can judge from continued conversation, rather a congenital trait than a symptom connected with his present trouble.

Patella reflex is exaggerated on both sides, but rather more upon the left. The ankle clonus is very well marked; ordinary reflex is exaggerated; he walks with the assistance of a cane, but with the "clinging" gait of spastic paralysis; the left leg weaker than the right; a very distinct reflex can be obtained from the tendon of the triceps extensor cubiti. Discharged relieved.

SUDDEN ATTACK OF HEMI-ANÆSTHESIA WITH SLIGHT MOTOR PARALYSIS: INCREASED TENDON REFLEX ON THE AFFECTED SIDE; DIMINISHED SWEATING ON THE AFFECTED SIDE; IMPROVEMENT WITHOUT ACTIVE TREATMENT.

CASE II. Peter O., aged forty-one. March 17th. Ten years ago had a chancre. Is a drinking man. Last January, the next day after shoveling snow, when he

was exposed to cold, began to notice numbness in right arm and leg, which has continued to the present time; diminution of power in same limbs; no pain.

March 18th. Tactile anæsthesia in right hand is very decided, two points being felt as one at one and one half inches apart; sensibility in right foot is diminished; ordinary sensation seems the same on both sides of the face, but says he does not feel any sensation in shaving on right side of face; sensibility to pain diminished on that side; the same condition of hemianæsthesia exists on the trunk; power of coördination diminished in right hand.

On the anæsthetic side, patella tendon reflex is much increased and ankle clonus is very decided; sensibility to Faradism not materially changed.

March 19th. Says he has more pain on right side than on left, and has a pricking sensation like pins and needles.

March 21st. Temperature of surface on both sides is the same as measured on thorax and on face.

Says that he does not sweat on paralyzed side; one quarter of a grain of pilocarpin was given subcutaneously causing profuse sweating; there was, however, a decided difference between the two sides, the anæsthetic (right) being very moist, while on the other the perspiration ran off in drops and streams; the temperature was at this time a little higher on the left side of thorax.

March 28th. Thinks he uses his leg better and that it has more feeling in it; the hand is also better; sensation, however, is still obscure.

April 11th. Discharged relieved, thinking that he is able to go to work.

Returned to the hospital about October 1st. Has been at work as a gardener through the summer. Now has a return of about the same symptoms.

GENERAL PARALYSIS; HEMIPARESIS; TENDON REFLEX NORMAL ON THE PARETIC SIDE, ABSENT UPON THE (COMPARATIVELY) NORMAL SIDE.

CASE III. Eben R., aged forty-six, was "dumped" at the hospital without a history. He answers questions well enough but it is difficult to get a very connected story from him. He has been employed in a hotel, but it is not clear in what capacity, whether as engineer or cook.

He complains only of weakness; says he was well up to a few days ago when he vomited, which he attributes to the irregular habits and abundant opportunities for eating incident to his occupation.

His manner is peculiar; expresses himself as satisfied with everything about him, including his own condition, although he is weak and passes his urine in bed; is at times delirious; a little slurring of some of his words.

A few days after entering there was apparent a decided weakness of the right hand, which he could not put on top of his head, and the movement of the facial muscles about the mouth was a little less marked on the right side.

In the absence of history of previous disease it was remarked at a clinical lecture that although it was possible that his mental and bodily condition might be the result of a slight hemiplegia, or rather a localized lesion giving rise to a hemiplegia, yet the probability was strongly in favor of "general paralysis." It was then found that friends had recently visited him who stated that he had not been in his right mind for some years,

¹ The Lancet, December 4, 1880.

² Ibid.

that he had been careless about his money, and his wife had not considered him capable of taking care of himself for some time.

A curious condition of tendon reflex was noticed. Upon the right (paretic) side the patella reflex was about normal. A certain amount of ankle clonus could also be developed in the corresponding foot, though not very persistent. With a slight degree of pressure there could be got five or six movements with about the usual rapidity and diminishing intensity. On the left side there was neither patella reflex nor ankle clonus.

This condition was supposed to be due to (1) the absence of tendon reflex found in a certain though not very large proportion of cases of general paralysis,¹ and (2) the exaggeration of tendon reflex and development of ankle clonus supposed to be connected with degeneration of the lateral columns of the cord either independently (when it is usually bilateral), or secondarily to cerebral lesion as probably happened in all three of the cases reported here.

If he had had no hemiplegia he would probably have had no tendon reflex, but the local cerebral lesion was able to produce an excitant effect on the lateral columns of the cord upon the right side sufficient to neutralize the effect of the general paralysis.

The following two cases illustrate a not very uncommon class, where the diagnosis remains doubtful on account of the favorable termination. It would not be at all difficult to think of them as incipient myelitis, both from the character of the exciting cause, usually exposure to cold, and from the symptoms pointing to an affection of the lower part of the spinal cord. If they afterwards passed into the classical transverse myelitis the initial symptoms would appear characteristic, but recovery leaves us in doubt as to just how far the lesions have advanced, whether to some slight organic changes, such as may readily be repaired, or merely to a disturbance of the circulation (congestion or anaemia?).²

CONGESTION? OF SPINAL CORD.

CASE IV. John Hogan, forty-two, boiler maker. Was in hospital last January with chronic bronchitis.

April 28th. Four months ago began to have cold feet; numbness and feeling of pins and needles; pain in calves; legs drawn up at night; can walk but cannot stand very long on account of weakness; no feeling of constriction about body; no pain in back; bowels constipated; has some cough and pain in chest.

Attributes his trouble chiefly to lying on his back on the cold iron when riveting boilers from the inside.

April 29th. Peculiar sensation in legs below knees; on touching legs with point of a knife apparently some hyperaesthesia; says he can feel the touch of the knife all over the leg; tendon reflex present but not very marked. Caps. Hot bath to feet and legs.

May 2d. Discharged well.

CONGESTION? OF SPINAL CORD; UNILATERAL FACIAL PARALYSIS.

CASE V. Edward B., aged forty six, long-boreman. Has had a cough with expectoration for which there are no physical signs to account.

¹ See paper by Dr. J. C. Shaw, *Arch. of Med.*, 1879, vol. ii., pp. 16-50.

² Those who feel entirely free from the doubt above expressed as to the precise condition of the cord may wish to consult many recent textbooks with special reference to the anatomy of anatomical e. A. J. G. and the anatomy of Dr. M. S. in the *London Lancet*, March 26th, April 21st, 1881, Feb. on the Influence of the Circulation on the Nervous System.

On March 7th he had severe pain across small of back and in both hips; later in both knees and elbows; joints were swollen, slightly tender; no reddening; frontal headache.

On the 13th a facial paralysis made its appearance on the left side for which he was transferred to the nervous and renal service. The facial paralysis was then complete. The movements and sensations in his hands normal; sensation and perception of pain in feet much diminished; complains of pain between the shoulder blades and in the calves of the legs and feet; walks with a staggering gait, but nearly as well with eyes shut as with them open; cannot, however, stand with eyes closed; falls backward.

A few days afterwards it was found that tendon reflex sufficed to produce some twitching of the rectus femoris, but not enough to lift the foot. It seemed clear that there was no necessary connection between the facial paralysis and the paraparesis.

The treatment for the paresis of the lower portion of the body consisted of rest in bed, to which the patient somewhat objected as he was by no means unable to walk, and in cups near the painful spot in the back. The Faradic current at first produced little, if any, reaction in the facial muscles, while the galvanic did so. On April 24th it is noted that the facial muscles reacted to Faradism.

He was discharged relieved, being able to walk quite well, free from pain, and with the facial paralysis much improved.

ANOMALOUS FEVER ACCOMPANYING AND SUCCEEDING MEASLES; ERUPTION PERSISTENT AND DUSKY; DEATH; NO SPECIAL LESIONS EXCEPT A RENAL THROMBUS OF TOLERABLY RECENT FORMATION.

CASE VI. Lydia M. A., aged twenty-four, dressmaker, Myrtle Street, Boston. Apparently strong and well developed. Is said to have been insane several times, once after some acute disease, last time two years ago. Was taken sick on April 14th with an eruption appearing first on face. Continued to work until April 16th, when she "took cold;" was then seen by Dr. J. B. Ayer. There was then an eruption in crescentic patches on face and body. On the 20th this had faded on the body, but had run together on the face. Temperature 102° F. That night she was very much excited, and the next day could not be managed. The eruption on face was then quite diffuse, on the body fading; eyes had been sensitive to light and had watered some but not as much as usual in measles.

April 22d. Tried to get out of the window. Temperature 98.2° F. Entered hospital.

April 23d. Dark-red, patchy eruption, with a somewhat petechial appearance. p. m. Not so delirious; tells a connected story. Has had (she says) no catarrhal symptoms, no cough, or sore eyes. Bowels constipated; temperature 101.5° F.

April 24th. Eruption fading from body, distinct on abdomen; hands lighter color; tongue red and dry; temperature, morning, 101°, evening 103° F.

April 25th. At time of visit patient lying in bed delirious, cheerful, and singing a song of which the words were mostly incoherent, but into which she incorporated, with tolerably correct rhythm, remarks in reply to those made by bystanders or to questions. Her hearing and mental perception seemed very acute. Measle-like eruption persists on lower part of abdomen chiefly, but also on chest, arms, and legs; face flushed

and of a dusky red; tongue dry but not black; lips dry and red; temperature from 103° to 104° F.; urine, color normal, acid, specific gravity 1027, albumen trace, abundant deposit of amorphous urates.

April 26th. Eruption fading; delirium about same; temperature from 101° to 102.5° F.

April 27th. Much quieter; eruption faded, but still perceptible; flush nearly gone from face; pulse 140, regular and feeble; expression is rather one of indifference and weakness than of stupor; respiration not hurried; temperature from 101.5° to 102° F. (bath and quinia).

April 28th. Almost unconscious; flush nearly gone from face; eruption on body dusky but distinctly visible; pulse 148; temperature from 102° to 104° F.

April 29th. Died.

Autopsy by Dr. E. G. Cutler. (Only the more essential points given.)

Lungs containing many hemorrhages. A dense organized thrombus, light and yellowish, which plugged the primary branch of the pulmonary artery on the left side. Left lung filled with small hemorrhages.

Spleen two and one fourth ounces. Rather light, with here and there punctate hemorrhages.

Intestines normal. Stomach with punctiform hemorrhages.

Kidneys. Left, four and one half ounces; tubules rather cloudy; artery healthy; vein contained a thrombus, which was quite adherent to the wall, it continued only into ascending vena cava, and was lighter colored and older in that portion. Right, three and three fourths ounces; vessels healthy.

Brain. Membranes were considerably injected, chiefly on the left side. On section, aside from tolerable amount of injection, nothing was found in the great centres.

Uterus and ovaries not abnormal.

TYPHUS; MEASLES.

CASE VII. Fanny B., aged twenty-five, entered the City Hospital, April 2, 1881. Her case was diagnosed as incipient phthisis, there being some slight râles below the clavicles. She was discharged April 28th. During her stay she had occupied for two or three days a bed next to one of the cases of typhus reported in the JOURNAL of September 8th. This was probably about April 14th to 16th. On the evening of the day of her discharge, April 28th, she was restless and thirsty at night. When first seen on May 2d she was feverish with a quick pulse and general pains. As her history pointed to pulmonary trouble, although no cough or expectoration was then present, her lungs were examined with negative results. On the next day a slight dusky eruption appeared on the face. On the body and arms an eruption of small pink spots, much like rose spots. There had been one loose defecation. The next day, May 5th, the eruption a little more copious; the face with a dusky flush, a little swollen; on the body the eruption is still papular. On May 6th eruption dusky and run together in dark-red patches mingled with spots more or less resembling rose spots. It covered the whole body and limbs. On the 7th and 8th it had begun slightly to fade. During this time she complained first of severe frontal headache, then became stupid with some mild delirium. The bowels, with the one exception already noted, were much constipated. At no time were there any pulmonary symptoms whatever. On the 10th of May the temperature

began to fall rapidly and steadily to the normal point, which it reached on the morning of the 15th, and there remained. As her strength was somewhat slowly re-established she reentered the hospital on May 21st.

The interest of this case lies solely in the diagnosis. She was seen two or three times by gentlemen connected with the Board of Health, one of whom pronounced it a case of "measly typhoid," another "typhoid measles."

To take the two parts of this diagnosis separately it is obviously much more difficult to eliminate the typhoid than the measles, but it seems to have differed from the former in the length of the disease, since a typhoid so severe as this does not usually terminate in so short a time, nor with so abrupt and definite a defervescence; in the absence of diarrhoea, not, to be sure, very conclusive; and especially in the character of the eruption, which although described as *like* rose spots at first, was most decidedly *not* rose spots at a later stage, and which involved very thickly the *whole* body. None of the several gentlemen who saw the case considered it a *typhoid* eruption, although some of them were equally sure it was not *typhus*. It certainly resembled very closely the eruption in one of the cases reported in the JOURNAL of September 8th. The period of its appearance was also earlier than is usual in typhoid.

As to the measles, the disease was, to be sure, present in the house where she lived, but if this attack originated there we must assume an incubation of either twenty-six days or twelve hours. When she was in the hospital the first time she was not in the ward where contagious diseases are placed. It is very doubtful whether the eruption of measles can be so modified by a debilitated constitution as to assume any such form as in this case. There were no catarrhal symptoms. And, lastly, when in the hospital the second time, in another ward, she was attacked with febrile symptoms on May 28th, succeeded by a (slight) loose cough and a highly characteristic eruption of measles on the 30th.

The slight physical signs at the apices of the lungs noticed when she first entered the hospital completely disappeared, and there have been up to the present time (September) no further symptoms of pulmonary trouble.

TYPHUS?

The following case was seen with Dr. Clement, of Roxbury. I regret that neither of us preserved any more complete notes.

CASE VIII. A man, English by birth, but having resided in this country for some years, had recently returned from a visit to the old country. He was first seen in Dr. Clement's office on April 7th, having worked the day before. His temperature was then 103° F. From the 12th to the 15th his temperature was from 104° to 106° F.; he had much active delirium; there was no diarrhoea; the eruption somewhat resembled rose spots, more thickly crowded than I have ever seen them, and covered the body.

On the 21st he was fairly convalescent, and advanced very rapidly to complete recovery.

No other cases occurred in the neighborhood.

—Virchow will soon be sixty years of age, and preparations are being made in Germany for a suitable celebration of the occasion.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY.

D. R. OLIVER, M. D., SECRETARY.

PROCEEDINGS OF SECTION OF CLINICAL MEDICINE AND MEDICAL PATHOLOGY.

MAY, 1881. DR. H. I. BOWDITCH presiding.
DR. F. C. SHATTUCK read a paper entitled

A CURIOUS ENDEMIC.

of which the following is a brief abstract:—

Early in October, 1880, M. D., a vigorous seaman, twenty-five years of age, consulted me at the outpatient department of the Massachusetts General Hospital. He came up from Provincetown for advice, and related the following interesting facts.

June 5, 1880, he sailed on the schooner *Nellie* Swift from Provincetown for the Grand Banks on a fishing voyage. The crew consisted, he says, of seventeen men and the captain. About August 1st one of the crew, a Portuguese, began to complain of soreness in the calves of his legs and a "dead" feeling in his ankles, which was soon followed by swelling of these parts. No headache or vomiting. This man was sent home. Soon after others of the crew began to be similarly affected, and, according to my informant, every single one of the ship's company has been thus affected since then in varying degrees of severity. The faces and bellies of some of the men swelled, and the captain "took water out of the privates" of some of them. One man is now at Provincetown so ill that he is not expected to recover. My patient complains chiefly of pain in his feet and legs, which have been considerably swollen. The swelling is now confined to his ankles and feet, and is less marked in the morning than in the evening. He is rather weak, and sweats easily, the sweat having a peculiar sour smell, he thinks.

Very careful physical examination failed to reveal any change in the viscera of the chest or abdomen. The urine was examined by Professor Wood himself, and found normal in every way.

He was given some simple remedy and told to come back in a week, which he readily promised, but failed to do. A week later, however, a friend and ship-mate of his came to me and told me that the first man was doing well. This man had also been affected in the same way as the other, — pain, numbness, and swelling of the legs, with general *malaise*, — but considered himself as about well when I saw him. Physical exploration and examination of the urine were negative in his case also.

Both men were carefully questioned as to the cause of this curious outbreak of disease, but no clue to it was obtained.

The schooner — as is the custom with many of the Provincetown fishing vessels — passed the previous winter in the fruit trade with the West Indies, visiting Nassau among other places.

They knew of nothing peculiar or unusual about the ship in any way. Other vessels from Provincetown started about the same time for the same fishing grounds, laying in supplies of water and provisions from the same source as the ship which single and alone had any sickness aboard unusual either in character or amount. Both of the men whom I saw were positive that the water was to taste and appearance

good, fully as good as they had been accustomed to on other voyages and other vessels. Their testimony on this point is at variance with that of the steward.

Learning that a number of the cases had been under the care of Dr. J. M. Crocker, of Provincetown, I wrote to that gentleman, of whose kind reply the following is an abstract:—

"PROVINCETOWN, October 15, 1880. Some five or six of the crew of the *Nellie* Swift have been under my care. Fifteen of the nineteen men belonging to the schooner have been attacked in precisely the same manner, though in different degrees of severity. The last case proved fatal last Tuesday. The feet, legs, and thighs were badly swollen; the penis and scrotum immensely so. There was dyspnea and the physical signs of effusion in the chest. The urine was scanty, high colored, free from albumen, but contained a few granular casts and was filled with fungi. At the autopsy serum was found in the pleural, pericardial, and peritoneal cavities; the heart was flabby, but otherwise normal; the kidneys were normal in appearance and size; the spleen was unusually small. There have been to my knowledge no hemorrhages, and no symptoms pointing to scurvy, save oedema of the ankles. The steward says that the drinking-water first used was thick and ropy, but none of this is now left."

The questions now arise as to the nature and cause of this outbreak of disease. There can be no doubt that it was due to a poison of some kind connected with the vessel, possibly with the water casks; for, it must be remembered, the water and other supplies of all kinds were drawn from precisely the same sources as were those of other vessels the crews of which remained perfectly healthy. But farther than this the facts at our disposal do not permit us to go.

While fully conscious of the meagreness of my report it still seemed to me worthy of being put on record, and the hope is indulged that some reader may be able, either from his experience or his reading, to throw light upon the source and nature of the disease.

DR. GARRETT suggesting trichinosis as a possible explanation, DR. ARBOTHNOT asked if it was usual for pain to begin in the calves, and if oedema was an early symptom. The reader thought not.

DR. CUSHING asked whether the solution might not be found in a peculiar weather condition existing at the time.

DR. SHATTUCK replied that this and apparently every other possible factor had been excluded, except what existed in the ship itself.

DR. BLODGETT said that the symptoms as narrated in the paper presented very little similarity to those of acute trichinosis. There was a notable absence of fever, no great pain, the swelling was of the nature of a serous transudation appearing in the form of anasarca, followed later by effusion into the serous cavities; and, more than all, the upper extremities were not reported to have been seriously affected. Two cases of trichinosis came to autopsy in Berlin, and were the subject of microscopic investigation by Dr. Blodgett. In one the parasites had been recently introduced into the system, and caused the death of the patient by the excruciating pain, the high fever, and consequent exhaustion attending their dissemination through the muscular system. In the second case the parasites had been taken into the system thirty years before, and were inclosed in regular envelopes which were often the seat of subsequent calcification, so that they appeared

as fine white points which were visible to the naked eye in the mass of the muscles. In this case there was the history of a sudden and acutely febrile attack, accompanied by great pain throughout the body at the time of the infection by the parasites, with a subsequent slow recovery, and ultimately death from another cause. In both these cases the trichinae were found abundantly in the muscles of the upper extremity as well as in those of the lower, seeming to be pretty evenly scattered throughout the body, of course being absolutely more abundant where the greatest masses of muscular tissue are found.

Everything seemed to point to the vessel itself as the source of infection in these interesting cases, though there was very little in the history of the vessel or of the patients which pointed to any recognized disease.

Dr. E. W. CUSHING asked if hamorrhages always occurred in scurvy; if the vessel might not have been infected, so to speak, so as to bring about a depraved condition of the blood in those on board, thus inducing the effusions which were the most prominent symptoms.

In relation to the remarks of Dr. Cushing respecting scurvy, Dr. BLODGETT said that the tongue and mucous membranes are usually affected in this disease, often to a very marked degree, while on this vessel there was no abnormal condition of these structures.

The chairman, in closing the discussion, said that the cases were certainly of unusual interest, and the report clearly showed that the cause must have been resident in the vessel itself or the supplies. He did not see how any diagnosis could be established without a complete report of the microscopic pathological appearances, the absence of which he deeply regretted.

Dr. E. G. CUTLER reported a case of

MEASLES FOLLOWED BY PLEURISY.

Mary McCree, a domestic in a family where several children had had the measles, was brought to the Carney Hospital, December 25th, with a well-marked case of the eruption. She had considerable fever, coryza, and photophobia, and the throat was somewhat sore. The 28th the eruption was disappearing, she felt quite bright, and the temperature was nearly down to the normal. She progressed fairly well, still remaining in bed, however, till January 3d, when she had a cough and pain in the right side, preceded by a slightly chilly sensation.

The temperature ran up to 102.6° F.; pulse 108. On the 5th the temperature was 103.2° F.; pulse 96.

There was found to be flatness on the right side from the base of the chest to just below the angle of the scapula, with absence of vocal fremitus and respiratory murmur behind. In front the respiration was exaggerated and at the side from the sixth to the eighth rib there was absence of respiration. Decubitus was on the right side.

For the next few days the effusion slowly increased till it reached the lower angle of the scapula behind, and in the axillary line ran up a hand's breadth further.

Four ounces of whiskey daily, quinine, five grains, three times a day, and iodine ointment were the remedies made use of. For the next few days sweating at night was a source of considerable annoyance, when, on the 20th, the effusion was found to be decreasing. On the 31st quinine diminished to two grains three

times a day, and iodide of potassium, one grain, given three times a day in bitter infusion.

February 3d, the effusion having come to a standstill, she was painted with cantharidal collodion, which raised several large blisters. This was continued for several days in the shape of flying blisters.

February 17th, cod-liver oil, a teaspoonful thrice daily, given in addition. Continued improvement. On March 6th the respiration was found to be normal over whole of chest, perhaps a little feebler over base behind. On percussion, resonance diminished over back below scapula over space as large as an orange. Painted with iodine ointment.

March 22d. Left hospital feeling well, and ready to resume work. Scarcely any difference detected in two sides.

In the ensuing discussion the subject of German measles was introduced, Dr. Blodgett reporting several cases, said to be röteln, terminating fatally. The chairman called for the opinion of the section on the question of its non-identity with measles, and if not as to any reliable diagnostic signs. The views held by most of the members speaking seemed to be strongly in favor of their identity, judging from their personal experience and from the lack of any generally accepted diagnostic points.

AN ACCIDENT WITH HYDROFLUORIC ACID.

[The subject of this distressing accident was Mr. Robbins, assistant in the chemical laboratory of the Institute of Technology. The patient is a man of very acute observation as well as a considerable degree of medical information, and I urged him to prepare an account of his experience with this acid, as it was the first case of injury of this kind I had ever seen. He acceded to my request, and the following paper, with a few unimportant changes, is his own account of this rare occurrence. ALBERT N. BLODGETT.]

"Fluorine as an element, is as yet unknown, it never having been isolated. The reason of this is that it is so destructive to all apparatus used for the purpose. It has been studied in its compounds and reactions, and its atomic weight has been determined indirectly. It is the only element which has no known compound with oxygen. It unites with many other elements as a monatomic acid radical and forms fluorides and also forms quite a number of double salts. Nearly all these compounds affect glass in the presence of moisture. Its hydride is a strong acid like that of chlorine and is a gas. It dissolves many of the metals to form fluorides, is easily absorbed by water, and hence the liquid acid is obtained by saturating distilled water with the gas. It has little effect upon platinum or lead, and is transported in gutta-percha bottles as it affects neither this nor wax nor paraffine, but its action upon other organic substances is often very energetic. I once attempted to redistill some of this acid as it is formed in these bottles, but neglected to dilute it one half as is usually done when it is wished to condense it without a freezing mixture. When heated, the gas began to come over without condensing. It charred the wooden box which surrounded the receiver and dissolved and volatilized a piece of writing paper which was exposed to it, leaving only a slight film of a gelatinous substance, probably the gum from the sizing of the paper. Concerning the action of this acid upon animal tissues little is known. Wurtz's dictionary gives the fullest account of it which I have been able to find. He says in sub-

stance that it corrodes the skin, giving rise to insufferable pain, and produces a deep ulcer which is very difficult to heal; small drops of it being sufficient to produce white and painful blisters. I had not read this, and was not aware of the great severity of the action of this acid, and I carelessly used the stump of a match, the wood of which was saturated with the acid above referred to, to remove the lime, etc., from the surface of a piece of porcelain so as to obtain the freest action on the part where I desired to catch a hole through it. When I first noticed that it was getting upon my fingers I washed them and greased them with tallow, and thinking they were sufficiently protected I went on with my work. For about an hour and a half I had the match in my fingers the greatest part of the time. Just before I got the hole through I noticed that the ends of my forefinger and thumb were beginning to be unresponsive, and I felt a curious sort of dull pain that perhaps might best be described by saying that my fingers "hurt" a little. When through, I washed them well, applied dilute ammonia water and washed that off, and then applied bicarbonate of soda, but these measures did not relieve the pain from soon becoming very uncomfortable, and I dressed the fingers in a mixture of linseed oil and lime water, as it felt more like a burn than anything else. This was done between eleven and twelve A. M. That afternoon I made an organic combustion, and the pain gradually increased till toward the last it seemed a question whether the furnace or my fingers were hotter. In the evening I began to feel alarmed and consulted Dr. Blodgett.

"At this time the ends of the fingers were white and very hard, so hard indeed as to dull the scalpel with which he endeavored to cut away some of the skin. The action was still going on, and as the depth to which it had penetrated could not be determined a dressing of cold cream was applied, and later vaseline was used, but neither seemed to allay the steady increase of the pain which now most nearly resembled the sensation of a burn when held near the fire. The only relief obtained was by the application of cold and this was only partial, and the only variation in it was from bad to worse, and at last it became the most severe pain I can imagine, and it was not till four o'clock the next morning, and with the aid of one hundred and ten drops of laudanum, that I was enabled to obtain sufficient relief for a broken nap. The next day the pain had subsided and the acid had penetrated quite a distance below the skin, rendering the flesh totally insensible and hard, having abstracted all the water from it. The other fingers were only slightly swollen, and the swelling did not extend back as far as the hand, showing that the blood was not poisoned at all. My usual good health was only temporarily and slightly impaired by the laudanum, but no other medicine was given. The course of treatment was to remove the destroyed tissue. This it was thought best not to do with the knife but with polishes alternating with frequent soakings in very hot water were constantly employed, which proved effectual, although slow, in its operation, it being fully twenty days from the time of injury till the slough was all removed. It was very dry and tough, and by no means inclined to separate from the surrounding tissues. In ten weeks I abandoned all dressings to the fingers and was able to use them a little. Only a small permanent loss of tissue has resulted, but now, after three months the parts are tender and the sensation is perhaps permanently destroyed. This agrees with the action of

this acid as stated by Wurtz, especially as regards the pain, but he does not mention the very important fact that no pain is felt for some time after contact with the acid, which in my case was between one and one and a half hours, and by this time the surface has become so hard that it is difficult if not impossible to check the action underneath, so that the damage is for the most part done before one finds it out.

"The difficulty in healing appears to consist in removing the slough, as it heals very quickly when this is out of the way, and after the first siege of pain, which is a long and severe one, the sore is no more painful than any other of equal size. I think that should I meet with the same accident again I should lose no time in washing it off as thoroughly as possible and then apply water-glass if this were accessible; if not I should use an alkali, and if possible soak the part in water as hot as could be borne, and then apply cold cream or some other dressing which will keep the part soft and also exclude the air.

"I have also heard of two other persons who have had misfortune with this acid; they were Dr. C. F. Folsom and a Mr. Lodge. The latter had the end of his thumb badly burned. It was three months in healing and quite a loss of substance resulted. I think that books on chemistry and teachers of the science should give greater precautions as to the use of this dangerous reagent. From the fact that this acid so effectually hardens animal tissue without distorting it I think it might perhaps be employed by the histologists as a hardening agent for the soft tissues, especially of the nervous system, as a means of preparing them for microscopical study. I have never known this experiment to be tried, and it would be necessary to use it in very dilute form, but as far as my own observation extends, the action on the tissues would be exactly what is desired."

Dr. E. G. CUTLER reported a fatal case of

CEREBRO-SPINAL MENINGITIS.

and demonstrated the brain and cord, which were typical specimens. (Reserved for publication.)

Dr. BLODGETT said he had recently treated a case in which the symptoms were confined to the back part of the head and the upper part of the spinal column, and were accompanied by wild delirium, and some retraction of the posterior cervical muscles, so that the patient was digging the head into the pillow. The case strongly resembled commencing "typhus fever" but recovered without further symptoms. There have been several threatened relapses, but these have always been averted.

A vote being taken as to the advisability of the meetings of this Section being continued during the coming year, it was unanimously decided to do so.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. W. SWAN, M. D., SECRETARY.

MARCH 12, 1881. Dr. REYNOLDS read a paper on

SAFEGUARDS IN PRIVATE OBSTETRICS.

which will be found on page 389 of this number of the JOURNAL.

Dr. MINOT said he agreed with Dr. Reynolds as to the importance of preliminary treatment in cases in

which the patient was not in a perfectly healthy condition, and he thought the physician should devote himself exclusively to the patient, both during the whole of labor and for a reasonable length of time afterwards. But with most general practitioners this is very difficult, if not impossible, in some cases, owing to the multiplicity of other engagements. He thought that, in cities at least, obstetrics should be in the hands of specialists, who should do no other work, and even refuse gynecological practice. Patients would be much better treated, and general practitioners would be relieved of a great burden.

DR. ABBOT said that while he agreed with Dr. Reynolds in his view of the importance of watching the condition of pregnant women before confinement, and treating any symptoms which might call for interference, he felt that such supervision should be exercised with a good deal of caution and tact to avoid exciting apprehension on the part of the patient and the friends. It was of the first importance that they should be kept in as cheerful a mood as possible, in view of the expected event. He cited two instances in his own practice where he apprehended the existence of albuminuria in the patient before labor, in which he refrained from asking for a specimen of the urine for examination on account of the peculiar timidity of the patients and those interested in them, and their knowledge of the significance of albuminuria. He was none the less prepared for symptoms which might arise from such a cause. In one there was a single convulsion after forceps delivery; in the other marked albuminuria occurring for the second time in the patient, leading to miscarriage. Both patients recovered.

DR. RICHARDSON remarked that in Dr. Abbot's first case preliminary attention might have averted the symptoms, and stated further, in reply to questions, that he thought that with due preparation convulsions may be very frequently — not with absolute certainty — avoided.

DR. MINOT stated that one of the duties of the physician was to point out danger, — at least to the friends. Under the circumstances detailed he thought it was his duty to procure and examine the urine.

DR. WELLINGTON said that it was practically difficult to attend minutely to the patient some time before her labor, and where he lived such attention would be considered a piece of impertinence, and the physician would risk being told to wait until he was called. Of course, if a patient were threatened with convulsions, or were otherwise in a bad way, there was no question of the propriety of prompt interference. He would ask if it were the custom in Boston, as it was not in Cambridgeport, to give such special preliminary attention to the expectant woman without summons.

DR. FIFIELD remarked that one may judge of the future by the past, and if the care of which Dr. Reynolds spoke were in a large degree required the number of orphans should be vastly larger than it is in fact. He had certainly understood that Dr. Reynolds would make this a universal law. He agreed with Dr. Wellington that such attention would generally be considered a piece of impertinence, and thought that the nurse would be able to give to the physician sufficiently early announcement of bad symptoms. In the matter of the care of the patient after labor, Dr. Fifield said that the exhibition of calmants, opiates, etc., was carried vastly to excess, and quoted Mr. Humphrey, sur-

geon, as having said that he seldom prescribed opiates in his wards, as they produced, in his opinion, only a *quasi* delirium, a mockery of sleep. Dr. Ramsbotham had remarked that no word was more abused in the lying-in room than "exhaustion." Dr. Fifield, in his experience as surgeon, had never yet seen after an operation attended by considerable loss of blood that the patient was in any degree benefitted by opiates. In fact, many patients had slept their last sleep from a conviction on the part of the medical attendant of the necessity of sleep. Then, again, there was a bugbear as to the moving of patients after labor. His father, who had had a large midwifery practice for sixty years, and was familiar with the practice of the fat and sagacious Dr. Rand, — who caused his patients to *stand* whilst sheets and clothes were changed, — was likewise in the habit of requiring his patients to rise and sit on a chair immediately after the placenta was delivered, while the bed was being made. He had never been called back to a case of flowing. Goodale, of Philadelphia, in his *Lessons on Gynecology*, page 350, has said: "Since labor in general is a strictly physiological process there can be no sound reason why a woman should not sit up in bed, or even slip into a chair whenever she feels so disposed. Such movements incite the womb to contraction, and empty it and the vagina of putrid lochia. When these are offensive upright positions are to be insisted on, being, in fact, better deodorants than detergent vaginal injections. 'Roman women took baths on the fifth day after labor.' Bed-pans are pernicious."

DR. LYMAN said that some had misapprehended Dr. Reynolds's position, but as he understood the paper he was very much inclined to coincide with the reader. The difficulties of sufficient attention to the patient had been very much exaggerated. Under ordinary circumstances there was no difficulty in obtaining a sample of the urine, for example, or in notifying the friends of any apprehended danger. The patient and her friends, or even the nurse, are not the proper judges of the amount of attention due to the patient, and in case of suspicion of danger of convulsions it is the bounden duty of the physician to examine the urine. Dr. Lyman expressed his belief in the "puerperal month" following confinement, the dangers of subinvolution, displacements, etc., many of which may be obviated with perfect ease. Those women who are able to take their rest escape these troubles in a large measure. If the patient don't choose to pay for what she may consider unnecessary devotion on the part of the physician he can give up the case. The raising up of a patient immediately after a delivery was fraught with very great danger, as from thrombosis, rendered more liable by the state of hyperinosis which exists with the puerperal state. Time must be given for the equilibrium to become established. For his own part, Dr. Lyman said, he would be glad never to see another case of midwifery, but it would be very difficult to exclude such cases from one's practice without excluding the practice itself. In conclusion, he would venture a statement, namely, that in a practice of thirty-five years he had never, to his knowledge, had a patient return to him, or go elsewhere, with any of these unfortunate sequelæ of confinement. This he felt bound to ascribe to excessive care for the few weeks after confinement, and not to pure luck. The vast majority of cases of subinvolution of the uterus arise from just this want of care — too early rising after labor.

RHODE ISLAND MEDICAL SOCIETY.

A QUARTERLY meeting of the Rhode Island Medical Society was held in Providence, September 15th, the president, Dr. O'Leary, in the chair.

Dr. A. Remick presented a report of the Richmond meeting of the American Medical Association, with special reference to the work in the section on diseases of children.

Dr. W. R. White read an account of the centennial meeting of the Massachusetts Medical Society.

A discussion on the relative value of bovine and humanized vaccine virus was opened by Dr. W. J. Burge with a paper defending the use of humanized virus.

Dr. E. M. Snow said that humanized virus only is used in public vaccinations in Providence. This virus has been perpetuated since the time of Jenner, and now produces a vesicle on the eighth day exactly like the original. Carefully kept records in Dr. Snow's office attest the efficacy of this virus, and show no bad effects from its use. Dr. Snow reported the following case as evidence that this virus now gives absolute protection: A mother suffering from small-pox was removed with two children to the pest-house, where the mother died. The children were successfully vaccinated, and neither of them had variola. Dr. Snow agreed with other speakers that bovine virus produces more effect on the arm, but was not satisfied that it affords surer protection.

Dr. O. C. Wiggin has always used the bovine virus, and following vaccination often sees a diffused erythema resembling erysipels. He remarked that many practitioners are too indifferent to the cleanliness of the child's arm and clothing, and too often neglect children after vaccination.

Dr. F. W. Palmer presented the subject of antiseptic surgery, exhibiting the Lister spray and antiseptic dressings, and explaining in detail the precautions to be observed before and during an operation and at subsequent dressings. This method faithfully followed has recently yielded surprisingly good results in a crowded surgical ward in Rhode Island Hospital.

Dr. Caswell said that for three years he had used the antiseptic system universally in hospital practice, and was convinced of its immense value. The discussions in London this year and last show an unsettled opinion regarding some of the details. He had used the various substances proposed as substitutes for carbolic acid, — thymol, boracic acid, etc., but though more agreeable they had proved unsatisfactory. He had tried Callender's dressing also, but instead of one to twelve, the proportion of carbolic acid to oil recommended by the author, he had used one to thirty or more. He had seen blisters follow Callender's dressing of one to twelve.

Several gentlemen presented facts relating to the spread of malaria in Rhode Island.

Dr. S. Hunt, of East Providence, saw intermittent fever last year in Barrington, and this summer it appears farther up the river in Watchemoket and Rumford.

Dr. Garvin said that the malarial wave had extended up the Blackstone River as far as Lonsdale, and presented a report of eight cases observed by him there this season.

Dr. Remick reported malaria very prevalent this summer in the southern part of the city of Providence, in the neighborhood of Mashapaug and Spectacle

ponds, and gave a tabular report of twenty-seven cases observed in that locality this summer.

Dr. Lawton, of Cranston, reported that he had attended thirty cases of intermittent fever in the same region during the past two months.

Drs. William W. Hibbard, of Providence, and Herbert J. Pomroy, of Westerly, both Harvard graduates, were elected Fellows.

Recent Literature.

Bovine Tuberculosis in Man. An account of the Pathology of suspected cases. By CHARLES CREIGHTON, M. D., Cantab. 8vo. Pp. 119. London: Macmillan & Co. 1881.

In this book the author hopes to show that certain cases of tuberculosis in man present characters sufficiently distinctive to establish a relationship with the form of tuberculosis which occurs in cattle.

The most marked peculiarity of this disease is the tendency to localization in the form of flat or pedunculated excrescences on the serous surfaces, and which has given rise to many of the popular names: Perlseucht, German (pearly disease); Meerlinsigkeit, German (duckweed disease); Pommelière, French (potatoe-like disease); angle berries, Scotland; grapes, England. The glands are usually greatly affected, and hence, also, "gland disease."

Tubercles are found in all the organs, but especially in the lungs, where, in the later stages, they become confluent, soften in the centre, and form cavities, irregular in outline, with smooth and slightly thickened walls not communicating with the bronchi. The section of a lung thus affected gives roughly the same appearance that is seen upon cutting open a "crumpet."

The microscopic examination of these tubercles shows that they are composed of cells, varying in size. The largest and most characteristic of these, called giant cells, contain numerous nuclei, usually arranged parallel with and close to the wall. Grouped about these giant cells are others more closely resembling epithelium, and called epithelioid. Finally a third class are to be distinguished, which do not vary materially in size from the white blood corpuscles. These different classes of cells are supported by a reticulum, which, from its prominence, has caused certain of these little bodies to be called fibrous tubercles.

The author considers that there is always a tendency on the part of an infectious disease to the reproduction both of its gross appearances and its histological details, and he thinks this "mimicry of infection" for bovine tuberculosis to have been seen in the cases which he records. These are twelve in number, and occurred in rapid succession at Addenbrooke's Hospital, in Cambridge, England. They have not been so carefully analyzed as could be wished, acute and chronic cases being thrown together. (The disease in cattle is always essentially a chronic one.) Some of them (take Case IV. for example) are based simply on the gross appearances, and there is no record of a microscopic examination which would remove the doubt, at once raised in the mind of every pathologist, whether the cases were not cheesy and miliary pneumonia. Although he gives the similarity in appearance with bovine tuberculosis he fails to make clear how his cases differ from the ordinary form, the existence of which he admits, however; and the curious coincidence

of the non-occurrence of any such cases since he commenced to recognize the identity makes him appear a prejudiced observer.

He goes outside of his own observation to point out that many recorded cases of anomalous forms of tuberculosis are probably bovine, and endeavors to show that an outbreak in a work-house school in Bristol, which was considered as one of typhoid fever, associated, in four fatal cases, with tubercles, was probably due to this disease acquired from infected milk. He is unable to prove that the milk was infected, while it was shown that the sanitary condition of the school was very defective.

Many points in the pathology of tuberculosis are not exact enough to establish the identity of various forms on such coarse anatomical appearances as have been given by Dr. Creighton, and it must be left to the future to decide the questions embodied in this attractive book.

The Microscope and its Revelations. By WILLIAM B. CARPENTER, C. B., M. D., L.L. D., F. R. S., F. G. S., F. L. S., Corresponding member of the Institute of France, and of the American Philosophical Society, etc. Sixth Edition. Illustrated by twenty-six plates and five hundred wood engravings. Philadelphia: Presley Blakiston. 1881. All rights reserved.

In presenting the sixth edition of this voluminous work to the public the author excuses the limitation of the various subjects on the ground that the book is intended as a guide to amateur microscopists. The present edition is considerably enlarged, containing fifty additional wood-cuts and several fine colored plates.

The book opens with a lengthy chapter on the Optical Principles of Microscopes, which gives a superficial and unsatisfactory idea of the laws of optics as applied to the microscope, and is unaccompanied by a single mathematical demonstration or illustration. To this follows more than fifty pages descriptive of the various English microscopes, illustrated by such a profusion of wood-cuts as to resemble the catalogue of a microscope dealer more than a text-book. This section contains little or nothing of value to the student and might profitably be omitted, as it is essentially an advertisement for certain manufacturers. One thing is quite noticeable in this book: none but English microscopes and English manufacturers are considered, no mention being made of Hartnack or other celebrated continental makers if we except M. Nachet. To an American student such an omission flavors either of ignorance of continental work, or of an unwarrantable egotism in regard to British microscopes, both of which are out of place in a treatise purporting to be cosmopolitan. More than fifty pages are occupied in a description of "accessories," and here some foreign workers, such as Professor Wayland, Professor Rogers, and R. B. Tolles, are mentioned, though no notice is taken of many valuable appliances for microscopic study which have originated outside of Great Britain within the last ten years.

The chapter on the Management of the Microscope contains much really valuable information in regard to the technique of the instrument, but is burdened with matter which is useless in a work designed for an amateur. But few "amateurs" are interested to know the extreme variations in the markings of *amphypleura pella-*

cida or *pleurosigma angulatum*, or the opinions of various observers concerning the scale of a gnat under a power of 1350 diameters.

The formulæ for preservative fluids, coloring solutions, etc., are copied from well-known hand-books, and are destitute of directions applicable to the various tissues and structures. There is really but little instruction concerning actual practical work with the microscope in this huge volume. One gets the impression that the author is a collaborator rather than a laborer in this field of research.

The chapters on the various forms of vegetable and animal life exhibit the same incomplete and superficial treatment of these subjects. The facts have apparently been gleaned from the labors of others, and are often incomplete and faulty. Thus, in describing the exhibition of the circulation of the blood in the frog, the author directs that the frog be rendered insensible by chloroform, apparently never having heard of curare, an agent vastly superior to chloroform for all the purposes of such a demonstration.

The subject of microscopical geology and crystallography is disposed of in less than thirty pages, but contains the inevitable wood-cuts and lengthy speculations of the author upon the natural history of certain fossil shells.

As a work of reference this book is valuable in the way of alluding to a great number of subjects, and often referring to authorities from which more extensive information may be acquired. As a guide in the laboratory or as an aid in any particular line of research it is well nigh useless.

The book is clumsy and unwieldy in form, but is printed in clear, bold type on good paper, and gives evidence of great care on the part of the publishers. It is supplied with a very full and complete index, and its general appearance is exceptionally good.

Clinical Lectures on the Diseases of Old Age. By J. W. CHARCOT, M. D. Translated by Leigh H. Hunt, B. Sc., M. D. With additional lectures by Alfred L. Loomis, M. D. New York: William Wood & Co. 1881.

This volume of Wood's Library of Standard Medical Authors contains twenty-one lectures on senile diseases delivered by Professor Charcot, some of them before his class at the Salpêtrière in Paris, and translated into English, with ten lectures by Professor Loomis on the same class of diseases and embodying his teaching at his clinics in Bellevue Hospital.

Charcot's lectures are too well known in the original to require any better recommendation, alike to those who are familiar with them and to those who are not, than the medium of a good translation.

Dr. Loomis' lectures add considerable to the value of the book, especially to the American student.

— Sir William McCormac's energy and executive ability are still finding an outlet in the affairs of the late International Medical Congress, of which, it will be remembered, he was the honorary secretary. The Transactions of the Congress, in three large volumes, will, it is said, be ready for delivery to members before the close of the present year.

Medical and Surgical Journal.

THURSDAY OCTOBER 27, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.

HOUGHTON, MIFFLIN AND COMPANY,
NO. 4 PARK STREET, BOSTON, MASS.

AMERICAN GOUT.

ALTHOUGH modern medicine has materially advanced our knowledge of the clinical history and morbid anatomy of gout,—that highly respectable and venerable disease which has been handed down as a precious heir-loom from our ancestors,—yet its pathology still remains pretty much in the same state as it was sixteen centuries ago, when Aretæus was prompted to declare that “its nature was known only to the gods.” One of the last strongholds of humoral pathology, it still defies the scalpel of the medical examiner to lay bare its essential lesion. Within a comparatively short period, however, we have observed that renewed interest has been attracted to this subject (which, owing to its antiquity and persistence, already boasts a formidable literature), and papers, not only upon unequivocal gout, but also upon its latent and undeveloped forms and the isolated manifestations of the arthritic diathesis have appeared in current medical literature, and have led to renewed discussions upon the pathology of gout and its rational treatment.

One of the latest contributions to this department of clinical medicine is from the pen of Professor Da Costa, entitled *The Nervous Symptoms of Lithæmia*.¹ In this instructive and practical paper, Da Costa calls attention pointedly to a morbid state which he considers as coming properly under the head of lithæmia,—a state closely allied to gout,—“that does not bring with it the inflammation, pain, and obvious swellings of the gouty paroxysm, but which works more silently, is characterized by the abundance of lithic acid or lithates in the urine, frequently coexists with signs of mal-assimilation of food, and with aches and pains unaccompanied by any perceptible changes of the aching part. Hepatic derangement is also often found; and from this end of the chain the links are stretched through many vague, almost nameless, symptoms to outbreaks of true gout or to structural change in heart, vessels, and kidneys.” This imperfect gout Da Costa considers as preeminently the American form of gout, and as explaining a host of obscure symptoms whose relations have been and still are often misconstrued. It is evident, however, that America, though offering a favorable soil for this manifestation of the gouty diathesis, is not its sole producer. It seems to be attendant upon the “*sturm und drang*” of modern life, and even Englishmen are exchanging the old-fashioned art rheumatism for the lithæmic forms. In the first volume of a book, which has just appeared, on Indiges-

tion, Biliousness, and Gout in its Protean Aspects, Dr. Fothergill, of London, has much to say on this subject and promises more in the second volume. The peculiar nervous symptoms of this state—the vertigo, intermittent headache or neuralgia, muscular cramps and twitches, perverted sensation or anæsthesia, the sleeplessness, nervous irritability which passes for “nervousness” or “hysteria,” and excessive mental irritability or unaccountable lassitude—may very readily be mistaken for signs of organic disease of the central nervous system, but attention to the clinical history, and above all examination of the urine, will reveal the source of the symptoms to be a blood charged with excess of lithates, and so guide the attending physician to a successful course of treatment. Hygienic and dietetic methods, of course, occupy a high place, and diuretic mineral waters, with occasional purgatives, are of great service in the therapeutic management of such cases, while the pharmaceutical remedies are the citrate of lithium, and perhaps the iodide of potassium, or colchicum. A warning is given against the free use of nervous sedatives and anodynes, which, Da Costa says, should be reserved for especial occasions and used sparingly.

A number of illustrative original cases reported in the article appear to fully sustain the views set forth in this interesting and suggestive essay, which, coming from one so well qualified to speak upon clinical medicine, must attract considerable attention, not only to the disease itself, but to the special manifestations of gout on this side of the Atlantic. Whether or not gout, like cancer, is on the increase among civilized nations, as a sort of penalty for artificial conditions of existence, is a question which has scarcely passed the stage of speculation, but it is one which already has attracted considerable attention, and is well worth further study.

THE SANITARY INSPECTION OF SCHOOLS.

DURING the past year 2074 persons died in the State of Massachusetts over five years of age and up to fifteen, or during the school years. In the next fifteen years 2213 died of pulmonary consumption out of a total of 5191 for all ages,—a disease the chief causes of which are innutrition and rebreathing over and over again air which has been vitiated, or, in other words, taking into the lungs what has been very properly called the sewage of the atmosphere. There can be no question that our public schools propagate contagious diseases to a certain extent among the very young, and that their insufficient ventilation or bad sanitary condition often deteriorates the constitution to the point of establishing diseases which sometimes produce death, sometimes a lasting invalidism, making the individuals wretched, and sometimes simply enfeebled health, which imparts weakened constitutions to children and children's children. As the “child is father to the man,” and the man is the father of the race, no better nor more important matter in preventive medicine can be urged upon the public at the present time than the proper medical inspection of our schools.

¹ *American Journal of the Medical Sciences* for October, 1881, page 416, et seq.

While the matter is still in debate in Boston, it may be worth while to consider what has already been done in another city about three fifths the size of ours in the sanitary inspection of schools, with reference to which the last report states that the importance of this part of the public health service increases from year to year.¹ It appears that the medical inspection of schools² began in Brussels in 1874. Previous to that time the schools were briefly visited by the physicians appointed to attend the poor, the inspections consisting chiefly in exchanging compliments with the head master, and signing their names to the register with the remark, "nothing to note," or in removing children suffering from parasitic diseases. When the Bureau of Public Health was established in 1874, five physicians were delegated to the sole work of medical inspection of the schools. They give their attention (1) to faults in construction, heating, ventilating, size of class-rooms, seats, desks, windows, etc.; (2) to the temperature and daily condition of the air and all the causes tending to vitiate it; (3) to all the circumstances affecting the health of the well child: gymnastics, care of eyes, ears, teeth, skin, body, length of lessons, time of study, light, heat, ventilation, books, swimming lessons, instructive excursions, immediate closing of the schools when the temperature exceeds 82° F., accurate anthropometric records as means of constantly learning the conditions as to health of all pupils, and investigations into the best methods of intellectual development; (4) to rigid regulations regarding infectious diseases, including vaccination and revaccination, and to careful directions for the training of children below the normal standard of health. The result has been that *no one of the infectious diseases has reached the height of an epidemic* in Brussels since the establishment of their inspection of schools, although other cities of Belgium and Europe generally have suffered severely; that the general health of the pupils has improved; that the scholars have much more nearly than before that training which is suited to them individually, and that the public charitable and penal institutions are thought to be less resorted to.

The mere mention of these facts should stimulate every city in the United States to similar work. Probably no measure of public hygiene or education would bring in larger returns for the labor and capital expended. We shall shortly publish some interesting statistics in regard to the health of school-girls in the city of Cleveland. We are glad to learn that the New York State Board of Health has already begun a partial medical inspection of some of their schools, preparatory to more general work in that di-

rection, and sorry to intimate that no board or municipality has yet undertaken such an important step in Massachusetts.

MR. WARING'S REPORT UPON THE CONDITION OF THE WHITE HOUSE.

THE report of the results of the examination by Mr. George E. Waring, Jr., of the plumbing and drainage of the White House at Washington has been made public in the columns of the *Sanitary Engineer*. The examination was made before President Garfield's removal to Long Branch and was, therefore, in some respects, less thorough than would otherwise have been thought proper. Mr. Waring reports that his observations indicate a very much less unsafe condition than current reports would lead one to expect. So far as exposed to view the workmanship of the plumbing within the house seems to be reasonably good. The arrangement of the various soil pipes and waste pipes is such as is usual where the construction has been added to from time to time, as occasion requires, and as different plumbers suggested. Much of it is defective, not a little of it radically so. Considered as a whole, while they are free from some defects often found in the better class of houses in our cities, the plumbing appliances of the Executive Mansion do not conform to what are now accepted as the necessary sanitary requirements of a safe dwelling.

Without stopping to describe in this brief preliminary report the details of the work examined, it may be useful to say that not one of the soil pipes has anything like proper ventilation, and more than one of them has no attempt at ventilation whatever; that the tank from which the upper part of the house is supplied with water is subject to direct contamination from the main soil pipe and from the ventilator of an interior water-closet; that one of the most important water-closets in the house is a pan-closet; and that two of the water-closet compartments, one of which contains a urinal, are practically without ventilation.

The rest of the report is occupied with a detailed description of the defects summarized in the above paragraph, with recommendation for their removal and for alterations required in other less flagrantly obnoxious parts of the plumbing and internal drainage. The external drainage is not considered at all in the present investigation, which from the circumstances of the case is necessarily to be regarded as preliminary.

We understand that the temporary changes suggested by Mr. Waring are being executed. It is probably unnecessary, after the experiences of the past summer, to urge upon Congress the propriety of making suitable appropriations for putting the residence of the executive head of the government in the best possible sanitary condition which its construction, its situation, and the present knowledge of sanitary science, admit of. The continuance of the present defects, long since recognized as dangerous to the health of the occupants of the White House, is to be attributed to a want of means for their correction, and not to the neglect of those entrusted with the supervision of the internal arrangements of the building.

MEDICAL NOTES.

— Dr. J. S. Billings sails for home from Liverpool October 29th. The very appreciative reception accorded to him and to his address before the Congress in England was as little surprising as it was gratifying to his friends, who are many, at home.

— In the report of the city registrar of Providence for the month of September we notice that there is very much less typhoid fever in the city than usual at this season; there is very little scarlatina; there is no epidemic of diphtheria; the mortality from diarrhoeal diseases will cease with the coming cold weather, and on the whole, therefore, an unusually healthy autumn may be expected.

Intermittent fever, or fever and ague, is prevalent in some portions of the city. It is specially prevalent in that section of the city north of Mashapaug pond, between Fenner Avenue and Potter's Avenue, and in the neighboring portions of the town of Cranston. There is also some of the disease in the vicinity of Allen's Print Works and Branch Avenue. Cases have also been reported in other portions of the city, but not in any great numbers. There are probably more than one hundred cases of fever and ague in the city at this time. A more particular report upon the subject will be presented soon.

— Dr. Charles Pope, of South Shields, England, communicates to the *Lancet* a case of recovery after long immersion, in regard to which he says:—

"The interesting feature of this case is that the man was entirely under water, with the exception of his left hand and part of the forearm, twelve to fifteen minutes, and held in this position, his head and chest being tightly jammed against a wall by the weights which had fallen upon him and capsized his boat. His recovery can only be attributed to the mechanical pressure on his chest and the concussion interfering with respiration, and thus preventing his lungs being filled with water. There is no fallacy about the time of his immersion, as I have carefully investigated the matter; and the machinery necessary for removing the weights and extricating him from his perilous position required this length of time to be got in order.

NEW YORK.

— According to the official report prepared by Dr. John T. Nagle, Register of Vital Statistics, the mortality in the city from zymotic diseases during the quarter ending September 30th amounted to 1910, 338 of the deaths occurring in public institutions. The deaths from the various diseases were as follows:—

	Total.	In Institutions.
Small-Pox	73	62
Measles	79	7
Scarlet Fever	355	4
Diphtheria	443	7
Croup	117	2
Whooping Cough	95	—
Typhoid Fever	147	60
Typhus Fever	15	40
Malarial Fevers	185	15
Pharyngeal Fevers	7	—
CerebroSpinal Meningitis	80	5
Other Zymotic Diseases	284	136

During the quarter there were 3009 deaths from diarrhoeal diseases, of which 243 occurred in public institutions.

— At ten o'clock on the evening of October 16th, a wing of the homoeopathic hospital on Ward's Island was destroyed by fire. It contained the laundry and kitchen of the institution, and also the sleeping apartments of the laundresses and other servants, all of whom were gotten out in safety. The patients from the other portions of the building were removed without injury, and were kept in the open air until the conflagration was over, when they were transferred to the wards most distant from the burnt wing, where no damage had been done by the water.

— At a stated meeting of the Academy of Medicine, held October 20th, Dr. Charles S. Bull read a paper on "Lesions of the Orbital Walls and contents due to Syphilis."

— It is said that the health officer, Dr. Smith, who owes his position (which is supposed to be worth about \$37,500 a year) to political influence, annually subscribes some nine or ten thousand dollars for "campaign purposes."

PHILADELPHIA.

— The momentous question which for some time had been agitating the County Medical Society was finally set at rest by a formal vote. On the notices for the stated quarterly meeting held October 19, 1881, it was stated that the question of the eligibility of women practitioners of medicine for membership in the Society would come up for discussion, having, by a resolution passed at a previous meeting, been made the special order of business for this meeting. In consequence of the general notice a large attendance was secured. When the matter came fully before the meeting it was found that no organized opposition existed, and the matter was decided, almost without a dissenting voice, by the adoption of a resolution declaring that it was the sense of the Society that women practitioners are eligible to membership "under the same laws and regulations governing the admission of men." This important step was taken simply as an act of justice, and not without full consideration of the question. The traditions of the Society and the feelings of many of the members were, apparently, so opposed to it, that hitherto the board of censors felt unable to endorse female candidates, but *nous avons changé tout cela*, and the names of several women practitioners have already been presented and recommended for membership in the Society.

— An interesting discussion on hypnotism, opened by Dr. C. K. Mills, took place at the last conversational meeting of the County Medical. The board of directors have made arrangements for the discussion of some topics in connection with syphilis. On November 23d Dr. John Ashhurst, Jr., will read a paper on the Clinical History of Chancre and Chancroid, and Dr. John B. Roberts one on the Relation of Syphilis to Scrofula. December 14th Dr. J. Wm. White will present the subject of the Prevention of Syphilis by Legislative Enactment, and Dr. E. S. Keyes, of New York, the Treatment of Syphilis in its Different

Stages. It is believed that this series of papers will prove of much interest and value.

— A new medical weekly of national scope is to be established in this city about the 1st of January, 1882, by Henry C. Lea's Son and Co. It is to be a continuation of the *Medical News and Abstract*, of which Dr. J. Minis Hays is editor.

— Dr. John Conrad, for many years pharmacist to the Pennsylvania Hospital, but living for some time a retired life, died in Germantown, Philadelphia, in his seventy-second year, on the 15th of October, 1881. Dr. Benjamin Coates, a well-known Philadelphia physician some time ago, but for many years retired from practice, died at the age of eighty-four years at his home on the 14th inst. He had been a member of the College of Physicians since 1827.

Miscellany.

BOSTON DISPENSARY.

The statistics of this institution for the year ending September 30, 1881, are as follows:—

The number of new patients treated at the central office is 13,388, classified as follows:—

MEDICAL DEPARTMENT.

Men, 2286. Women, 4153. Children, 2400. Total, 8839.

SURGICAL DEPARTMENT.

Men, 950. Women, 437. Children, 336. Total, 1723.

DENTAL DEPARTMENT.

Men, 265. Women, 404. Children, 512. Total, 1181.

DEPARTMENT FOR DISEASES OF THE SKIN.

Men, 647. Women, 254. Children, 207. Total, 1108.

DEPARTMENT FOR DISEASES OF THE NERVOUS SYSTEM.

Men, 19. Women, 26. Children, 5. Total, 50.

DEPARTMENT OF LARYNGOLOGY.

Men, 179. Women, 174. Children, 137. Total, 487.

The number of visits made by patients, old and new, at the central office, is 27,226, classified as follows:—

Medical, 20,439. Surgical, 6787. Total, 27,226.

The number of new patients treated in the districts is 12,755, classified as follows:—

Men, 2169. Women, 4778. Children 5808. Total, 12,755.

The results of treatment in the districts are as follows:—

Discharged cured or relieved	11,621
Sent to hospitals or removed from the districts	790
Died	366
Remaining under treatment	61

12,838

Remaining under treatment at last annual report	83
---	----

12,755

Number of new patients treated at the central office	13,388
--	--------

Total number of new patients treated at the central office and in the districts	26,143

A CASE OF INTERMITTENT FEVER.

MR. EDITOR.—In the JOURNAL of September 22d you call for the report of genuine cases of intermittent fever of New England origin. The following case has just occurred in my practice:—

My patient lives in a house built upon a slight elevation overlooking a meadow. About six years ago a road was built across the meadow, which appears to have interfered with the natural flow of the water, and since that time there has been, every spring and autumn, water in the cellar of the house amounting sometimes to a depth of several inches. With the exception of a case of acute pleurisy, in the spring of 1879, there has been no sickness in the house which could possibly be referred to this condition of the cellar.

I have dwelt at some length on the surroundings of the house for want of any apparent cause for the development of intermittent fever, but I find it difficult to discover any such connection because at the time this case occurred the cellar was dryer than at any other season of the year.

My patient was a girl of twelve, who has always been perfectly well. The first two weeks of August last were passed at Providence, R. I. With that exception she has never been twenty miles from Boston. On September 26, 1881, she got up with a headache and general feeling of sickness. Her mother supposed she had taken cold from exposure from driving about town in an open wagon two days before. A mild cathartic was given, but no physician was called at that time. On the 27th and 28th there was nothing worthy of note in the case. On the 29th she felt chilly in the morning, and was glad to be near the kitchen stove, although the weather was warm. There

was, however, no pronounced chill. The chilly feeling was followed by a febrile stage, as described by her mother. At night she felt quite well, and awoke the next morning expecting to go to school. At nine A. M., however, on September 30th she had a well-marked chill. Her mother, who, many years ago, lived in a malarious region in Iowa, said her daughter had all the appearances she had been accustomed to see in cases of intermittent. The chill lasted half an hour, and was followed by a state of fever.

I saw the patient at about noon, when she was in a profuse perspiration. Pulse 120, respiration 40, temperature 103° F. Ordered cinchonidic sulph., two grains, every three hours.

October 1st, four P. M. Has had no chill to-day, but, on the contrary, has felt, with the exception of some headache and ringing in the ears, as well as usual. Omit cinchonidic sulph.

October 2d, nine A. M. Had another chill. One hour later, pulse 120, respiration 36, temperature 104° F. Resume cinchonidia.

From that date until now there has been no return of the chills. Patient has been about house, and anxious to go to school. Except for the annoyance of an eruption of herpes labialis she has been as well as usual. She is still taking about eight grains of cinchonidia. J. WINTHROP SPOONER.

Hingham, October 7, 1881.

THE "LANCET" ON BULLETINS.

To us, as onlookers, it is abundantly clear that a physician in assuming responsibility for the effect of his bulletin is trying to bear a burden too heavy for him, and we believe our American brethren on looking back will cordially agree with us in this view. It comes to this, then, that a bulletin should be "the truth, the whole truth, and nothing but the truth;" and "the truth" should be simply a record of facts, well observed and precisely stated. The responsibility for the use of those facts then rests with the users of them — on the proper shoulders. So soon as opinions are added, sources of fallacy and error creep in, and the bulletin itself becomes the subject of debate. But it may fairly be asked if all the facts, especially those of serious import, need be stated, as symptoms of gravity are often merely temporary, and their public notification might cause unnecessary alarm. We are free to admit that in private practice such considerations may well be allowed some weight, but in his more public capacity the physician must regard himself as called upon to give a strict record of *all* the facts. In this country it is the custom to make bulletins err, if at all, on the side of extreme care to state all the unfavorable symptoms in the case. The result is the public have full confidence that nothing is being concealed and kept back from them — that they know the worst; and there is no room subsequently for a suspicion that possibly the medical attendants had not been quite alive to the gravity of the symptoms. Further, we think that, under such circumstances as we are supposing, the official bulletins should be the only public communications of the medical attendants in reference to the case. Let others, if they like, discuss the facts published; those responsible for the management of the case should be satisfied with announcing them in the official bulletins. Only those most able to give opinions know the full

danger of publicly expressing them, even on well selected facts, and the distortion such opinions are liable to undergo is notorious. But the public in reading bulletins want to be assured that they are put in possession as fully as may be of the actual facts of the case, and the physician or surgeon in charge may well content himself with the responsibility of stating them.

CLINICAL UROLOGY.

M. ROBIN reported to the Society of Biology in Paris two cases in which the patients suffered from diseases whose differential diagnosis, though very difficult by the ordinary means, was yet rendered easy by an examination of the urine. The first case was that of a boy aged fifteen, who presented obscure typhoid symptoms; the second was a patient of the same age with almost identical symptoms, except that in the latter case there was a slight hyperesthesia and a slow pulse. In the second case there was reason to suppose that the patient might be suffering from tubercular meningitis; examination of the urine resulted in the following observations: In the first case it was turbid, with a specific gravity of 1,013, and a slight excess of urea and uric acid was present. Nitric acid poured down the side of the test-tube containing the urine caused a number of superimposed zones to form in the following order: A stratum of uric acid, a transparent zone, a stratum of albumen, and underneath a blue ring due to the presence of indican. In the case of the second patient the urine had a reddish tinge, was clear, with a specific gravity of 1,032, and contained a very considerable quantity of urea; neither albumen nor indican was detected on the addition of nitric acid, but urohaematin was shown to be present. From this difference in the urine M. Robin diagnosed typhoid fever in the one case, and tubercular meningitis in the other, and post-mortem examination verified in each case the diagnosis. M. Robin states that this difference in the urine exists in all the cases which he has hitherto examined. In typhoid fever indican and albumen are always present, but only very rarely urohaematin. The latter substance, however, is sometimes present at the beginning of continued fever under certain conditions, such as pulmonary complications, hæmorrhage, facial erysipelas, or when the disease attacks a very robust individual, and assumes an inflammatory type. M. Robin concluded his remarks by stating that the presence of indican in urine affords a very valuable diagnostic sign of typhoid fever, for although we cannot say that the patient is free from the fever because the coloration is absent, yet when it is seen in the urine he must be said to be suffering from typhoid. — *Le Progrès Medical*, April 2, 1881.

WOMAN'S PLACE IN NATURE.

M. DELAUNAY has summarized the evidence supplied by the physical organism of woman, in proof of her "inferiority" to man. There can be no question on this point, the *Lancet* thinks, in the mind of the impartial student of anatomy, human and comparative. It is, however, necessary to explain what is meant by "inferiority." In its conventional use, and the meaning commonly attached to it, we have no right — even in a purely scientific sense — to speak of woman as in-

ferior. It is rather with her place in nature we should deal. All females are lower in the scale of development than males. M. Delannay makes a reservation in this respect when treating of the females of certain forms of life,—for example, insects, some fishes and reptiles,—but in doing so he falls into the common error of failing to keep in mind the *purpose* of the organism in reference to its ancestral or actual mode of life. In many lines of existence it is an advantage to be comparatively small and of little weight, and in the case of animals so situated the male is the smaller and the lighter. So is it with color, appendages, form, and the capabilities generally; these must all be studied for the purpose of estimating a direct relation to the mode of life. When this is done there will be found to be *no* exceptions to the rule that the male is superior, that is, superior in the sense of being better fitted for the purpose of the life of relation proper to the species, either in the history of its development or in its actual state. There is not, so far as we can see, anything new in what M. Delannay has to say on the subject. The evidence he adduces, of course, goes to prove that women are not intended for the higher forms of intellectual work, but in all their activities to be the help-

meets of men. One fact he mentions is sufficiently interesting to be reproduced, and it may strike some readers as novel, though it has long been recognized as an instance of the essential inferiority of woman's work, even in departments which she is especially prone to look upon as her own. He cites the historic fact that although there has been and are wonderful examples of the skill of women as practical musicians, and they take much pleasure in music, and devote much time to the acquisition of manual dexterity in playing on a variety of instruments, at the same time cultivating the sense of hearing and taste to a state of very high perfection, there has never been a great female composer! This is a significant circumstance, and might well form the topic of a homily in praise of that modesty which is not only the greatest glory of woman, but should be her protection against the misleading blandishments of her unsisterly sisters. Woman's place in nature is to "stand before" man, to be his "helpmeet," his counsellor, his friend in adversity as well as in prosperity, in the hour of sickness and weakness as in the time of health and strength, but she cannot usurp his place, and she is not his equal in stature of body or mind.

Deaths reported 2038 (no report from New Orleans): 1251 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 929, consumption 397, diar-

rhoeal diseases 302, diphtheria and croup 230, lung diseases 175, typhoid fever 136, small-pox 74, malarial fevers 69, scarlet fever 65, whooping-cough 19, cerebro spinal meningitis 16, puerperal fever nine, erysipelas seven, measles two. From *small-pox*,

Chicago 35, Pittsburgh 22, Philadelphia 11, New York four, Cincinnati two. From *malarial fevers*, New York 19, St. Louis 10, Philadelphia and Brooklyn nine, Baltimore six, District of Columbia five, Chicago four, Cincinnati and Nashville two, Boston, Charleston, and Holyoke one. From *scarlet fever*, New York 28, Pittsburgh 11, Brooklyn eight, Philadelphia seven, Chicago four, St. Louis three, Buffalo two, Baltimore and Providence one. From *whooping-cough*, New York and Boston five, Brooklyn three, Philadelphia, Chicago, Baltimore, District of Columbia, Providence, and Somerville one. From *cerebro-spinal meningitis*, New York four, Philadelphia, Chicago, Cincinnati, and Milwaukee two, Baltimore, Providence, Fall River, and New Bedford one. From *puerperal fever*, Boston four, Chicago three, Buffalo and Charleston one. From *erysipelas*, New York and Chicago two, Brooklyn, Milwaukee, and Providence one. From *measles*, Buffalo two.

Four cases of small-pox were reported in Boston, three in Cincinnati, and 37 in Pittsburgh; diphtheria 33, typhoid fever 31, scarlet fever one in Boston; diphtheria eight, scarlet fever one in Milwaukee.

In 40 cities and towns of Massachusetts, with a population of 1,040,574 (population of the State 1,783,086), the total death-rate for the week was 23.50 against 21.01 and 21.98 for the previous two weeks.

For the week ending September 24th in 149 German cities and towns, with estimated populations of 7,919,242, the death-

rate was 22.4. Deaths reported 3412; under five 1733; pulmonary consumption 425, diarrheal diseases 196, diphtheria and croup 139, scarlet fever 124, typhoid fever 65, whooping-cough 47, puerperal fever 16, measles and röteln 11, small-pox (Metz, Aachen) two. The death-rates ranged from 12.7 in Frankfort to 36.3 in Posen; Königsberg 25.8; Breslau 27.9; Munich 26.7; Dresden 21; Berlin 23.6; Leipzig 18.5; Hamburg 19.9; Hanover 13.5; Bremen 17.3; Cologne 21.2; Frankfort 12.7; Strasburg 19.2.

For the week ending October 1st in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 17.9. Deaths reported 2607: scarlet fever 130, diarrhoea 106, fever 81, measles 43, diphtheria 18, small-pox (London 15) 16. The death-rates ranged from 13.2 in Plymouth to 24.2 in Hull; Sheffield 15.9; Leeds 16.3; London 16.6; Birmingham 17.9; Bristol 18.9; Manchester 22.5; Liverpool 22.7. Edinburgh 17.1; Glasgow 18.2; Dublin 17.8.

For the week ending October 1st in the 21 chief towns of Switzerland, population 479,934, there were 28 deaths from diarrheal diseases; acute diseases of respiratory organs 20, diphtheria and croup three, whooping-cough three, typhoid fever three, scarlet fever two. The death-rates were, Geneva 17.5; Zurich 21; Basle 15.1; Berne 28.1.

The meteorological record for the week ending October 15th, in Boston, was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM OCTOBER 15, 1881, TO OCTOBER 21, 1881.

MAYRDER, D. E., major and surgeon, medical director, Department of the Missouri. Granted leave of absence for one month. S. O. 207, Department of the Missouri, October 11, 1881.

CONSON, J. K., captain and assistant surgeon. Confirms telegraphic instructions of this date directing him to report to the commanding officer, Battalion Fourth Artillery, at Fort Yuma, Cal. S. O. 4, Department of Arizona, October 5, 1881.

DICKSON, J. M., captain and assistant surgeon. Granted leave of absence for four months. S. O. 232, A. G. O., October 13, 1881.

ADAMS, G. W., captain and assistant surgeon. Upon relinquishing unexpired portion of his present leave of absence, reports from duty in Department of the East, and to report in person to commanding general, Department of Dakota, for assignment to duty. S. O. 230, A. G. O., October 11, 1881.

KIRKPATRICK, H. S., captain and assistant surgeon, Fort Porter, N. Y. Granted leave of absence for one month, with permission to apply for two months' extension. S. O. 182, Department of the East, October 11, 1881.

The profession in Boston is warned against an individual calling himself a physician, claiming to be sick and penniless, and seeking aid on the strength of a forged letter from Dr. Messer of Cincinnati.

The ninth annual session of the American Public Health Association will be held at Savannah, Ga., November 29th to December 2d, inclusive. AZEL AMES, JR., *Secretary*.

SUFFOLK DISTRICT MEDICAL SOCIETY. — There will be a stated meeting at 19 Boylston Place, on Saturday, October 29th, at eight o'clock. Medical communication. Review of President Garfield's Case, by Dr. J. C. Warren. All members of the Massachusetts Medical Society are invited to be present and to join in the discussion. H. C. HAYES, M. D., *Secretary*.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next regular meeting will be held at the Medical Library Rooms, 19 Boylston Place, on the first Thursday of November, at 10.30 o'clock A. M. Dr. Ephraim Cutter, of New York, will read a paper entitled Contribution to the Treatment of Uterine Hyperæsthesias by Iodoform and Cotton. Profession invited.

HENRY M. FIELD, M. D., *Secretary*.

BOOKS AND PAMPHLETS RECEIVED. — Practical Anatomy: A Manual of Dissections. By Christopher Heath, F. R. C. S. Fifth Edition, with twenty-four Colored Plates and two hundred and sixty-nine Engravings on Wood. Philadelphia: Presley Blakiston. 1881.

Eczema and its Management. A Practical Treatise based on the Study of two thousand four hundred Cases of the Disease. By L. Duncan Bulkley, M. D. New York: G. P. Putnam's Sons. 1881.

RECURS.

CLINICAL LECTURE ON DISEASES OF WOMEN.¹

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

BY PROF. T. GAILLARD THOMAS.

CASE I. URETHRAL CARUNCLE.

GENTLEMEN: The first case which I shall show you to-day is the counterpart of one which you saw earlier in the course; but I have thought it well to bring the patient before you both in order to impress the subject which it illustrates the more clearly upon your minds and also because I trust that this good woman will consent to have her trouble removed by a trifling operation before she leaves us to-day.

Her name is Catherine B., and she was born in Ireland. She is fifty-four years of age, and has been married thirty-four years; but has never been pregnant.

How long have you been sick, Mrs. B.? "Two or three years." In what way have you suffered? "Principally from pain in passing my water."

She informs me privately that she wants to sit at the water-closet all the time; so that she seems to suffer constantly from the most severe vesical tenesmus. I judge that this sums up pretty much all her trouble; but it will, at all events, be best to ask a few more questions in regard to her symptoms.

Are you troubled by anything else? "I have a little white discharge." Anything else? "No." How often do you have to pass your water? "All the time during the day, and three or four times at night." Do you know any reason why you have never borne children? "No."

Suppose now that a woman should come to the office of any one of you and tell you that she had great difficulty about urination, that as soon as she emptied her bladder she felt like emptying it again (in fact, was constantly straining and bearing down), and that the passage of the urine gave her intense pain. You would very likely suppose that there was a considerable amount of cystitis present, and this idea would, no doubt, be confirmed when you found a slight quantity of pus in the urine. Perhaps it would not occur to you that pus is very apt to be found in the urine of patients suffering from leucorrhœa; and so having arrived at a conclusion, although not having made a diagnosis, you would prescribe a course of medication for the cystitis. But such a patient as this might take medicine for years and not experience any relief; and when you had found that although she had been taking your medicines for a long time, she was not at all improved, it would probably occur to you that you had better make a physical exploration.

One great object that I have in presenting this case is to impress upon you the importance of making an examination when there is any trouble with the bladder or urethra; for it is just as essential as when there is any uterine difficulty. But suppose the patient refuses to allow any examination: are you on that account to refuse to have anything to do with the case. I would not advise you to do so, unless you prefer losing patients to keeping them. Although the idea of an examination is very repulsive to most women, and many of them hesitate about submitting to it at first, there

are very few patients indeed who will refuse when they have entire confidence in their physician, and the subject is presented to them in the proper light. It is better, therefore, in such a case to prescribe a placebo for a few days, and when the patient really begins to appreciate the fact that you cannot treat her intelligently until you have made an examination, in order to find out exactly what the trouble is, she will no longer hesitate about the matter.

As soon as we commence our exploration here, we find that there is a urethral caruncle present, similar to that found in the case of the old lady from Long Island, who came to us earlier in the session; and then we know at once why it is that this patient has been suffering so intensely. The irritation set up by it corresponds to that caused by an elongated uvula; which can only be perfectly cured by the snipping off of a portion of its tissue. So here, in order that the patient may be relieved of her distress, this little caruncle (which is a kind of small polypus growing from the urethral walls and hanging outside of the orifice of the canal) should be drawn down and removed either by twisting or cutting. With the exception of the sterility, this caruncle accounts perfectly for all the symptoms. It is on account of the presence of this very insignificant-looking little growth that the patient has been suffering all this distress for more than two years past; the only relief that she gets being when she is in bed at night, as lying on the back seems to lessen the amount of irritation. As to the sterility, it is impossible at present to say what has been its cause; but as the woman is now fifty-four years old, and long past the menopause, this point has no longer any interest for us. I am glad to announce that the patient very sensibly consents to have this little growth which is causing her so much trouble removed to-day, and, accordingly, as soon as she has been etherized, I shall have the opportunity of doing it in your presence. Such an operation I perform here principally for the sake of showing you the character of these urethral caruncles, because it is impossible to afford so large a class the opportunity of seeing much of the procedure, which of itself, indeed, amounts to almost nothing.

The patient being now completely anesthetized, and the parts exposed, those of you who sit sufficiently near can see the growth very well, I think. By means of the forceps, I first draw it out from the urethra, and then my assistant, Dr. Ward, will put a ligature around its pedicle for me; after which I propose simply to clip it off. We find that the little mass is so very soft, however, that the thread cuts directly through it, and so we are obliged to remove it by piece-meal; taking great care to get the forceps quite down to the base of the growth. I now adopt a procedure which is not at all difficult under the circumstances, and which is often of considerable service in cases like this; namely, the dilatation of the urethra by means of the little finger until the latter can pass up into the bladder itself. When the sphincter is stretched thoroughly, it has been found that a urethral caruncle is very much less likely to return. The canal is now dilated to such an extent that the fundus of the bladder can easily be reached, and now sweeping my finger over the internal surface of the viscus I find that there is nowhere any new growth upon it. Of course, if there were a stone, its presence would easily be detected by the same procedure. As you perceive, the hæmorrhage is quite free from the base of the caruncle, and sometimes, when it

¹ Reported by P. Brynberg Porter, M. D.

is not interfered with, this continues for ten or twelve hours. When we have taken the precaution of applying a styptic, however, there will be no risk whatever in sending the patient to her home.

I find that the os uteri is very small in this instance; but as this may be due merely to the physiological atrophy of the whole organ which follows the menopause, we would scarcely be justified in assigning the sterility which has been noted to this cause.

CASE II. ANTEVERSION OF THE UTERUS AND CHRONIC OVARITIS, WITH PROLAPSUS, DEPENDENT, APPARENTLY, ON LACERATION OF THE CERVIX.

Our next patient is Ellen O'K., thirty-five years of age, and a native of the United States. She has been married ten years, and has had two children and one miscarriage.

How long have you been sick, Mrs. O'K.? "About seven months." What have you complained of during that time? "Pain in my back and loins and down my limbs." What else? "A kind of lump in my side." Can you feel this all the time? "Not always." Is there anything else that you complain of? "My head troubles me a great deal." In what way? "There is a great lightness in it." How are you in regard to your monthly sickness? "I am not very regular." Do you suffer very much at this time? "Yes, a great deal." Have you the whites? "No." And that is all that you complain of? "Yes."

Before going on any further with the case, I may mention that the miscarriage which has been noted occurred subsequently to both her normal labors. It took place eighteen months ago, but you will notice that the patient dates the commencement of her present trouble only seven months since. The latter of her two children was born three years ago. The prominent symptoms in this case are: the fixed pain in the back, so common in uterine disease, pain extending down the thighs, dysmenorrhœa, and some rather indefinite trouble about the head.

On making a vaginal examination here we are at once struck with the abnormal condition of the cervix. In the first place it is found far back towards the sacrum, and, secondly, there is a laceration in it extending quite up to the vaginal juncture on both sides. Neither the cervix nor the body of the uterus were very sensitive to the touch, but as soon as I resorted to conjoined manipulation the patient began to complain of great suffering. This struck me somewhat by surprise until I discovered two round masses down in Douglas's cul-de-sac, when the sensitiveness on pressure, as well as the constant pain in the back, of which the patient complains, were at once fully explained.

The patient's position was now changed to the side, and Sims' speculum introduced, when the diagnosis which I had previously made was confirmed. The everted lips of the torn cervix were seen to be very red and angry-looking, and from their surfaces was pouring a profuse leucorrhœal discharge. Yet, you will remember, the patient said she had no leucorrhœa at all. This is not uncommonly the fact, and one of the points which I wish to make in connection with the present case is that it is not ordinarily safe to trust a patient's statement in regard to the absence of leucorrhœa. The diagnosis here, as I said, was verified by means of Sims' speculum, and was as follows:—

- (1.) Extensive double laceration of the cervix.
- (2.) Anteversion.

(3.) Prolapse and engorgement of both ovaries.

Such a condition of affairs is, of course, quite sufficient to account for all the symptoms complained of by the patient, including the dysmenorrhœa and the head symptoms.

There is another point of great interest in connection with the case, and that is, When did all this occur? Such a laceration of the cervix as this could not have been caused by the miscarriage (which, as the patient informs me, was only at the third month of utero-gestation), and in all probability it took place at her last natural delivery, three years ago. Why the symptoms of which she now complains should not have made their appearance earlier it is difficult to say, but such a circumstance is by no means uncommon in medical experience. Thus, disease of the kidney resulting from scarlatina often escapes notice entirely for a long period after the attack which gives rise to it.

What is the prognosis here? In a general way I may say that whatever we may do for this patient, we certainly cannot cure her. I believe it to be impossible to put her in as good a condition as she was before the birth of her last child, but, nevertheless, I do not doubt that she can be relieved of all her symptoms. Where, then, shall we begin the treatment in this case? With the ovaries? I think not. In my opinion all the ovarian trouble here present has had its origin in the laceration of the cervix uteri. Our first duty, then, is to restore the cervix as nearly as possible to its normal condition by means of an operation. The patient should be kept strictly confined to bed for ten days, during which time her bowels should be kept soluble, and copious vaginal injections of hot water should be frequently employed. While thus being kept in a state of complete rest, the uterus should be replaced, and thus would be caused a removal of pressure from above and of traction from below by the heavy vagina. In a fortnight (or perhaps it might be necessary to wait a month) the cervix should be sewed up, and we would then have accomplished two things:—

(1.) The engorgement of all the pelvic organs would be relieved.

(2.) A source of future irritation would be removed.

If the patient were losing too much blood at her menstrual periods, it would be of service to apply the curette to the lining membrane of the uterus, but as this is not the case here such a procedure will not be necessary. It is possible that this uterus, having once been restored to its normal position (it being so much lighter now than formerly), would remain there, but if it did not an appropriate anteversion pessary could easily be worn as long as it might be required.

The return of the ovaries to their previous condition would necessarily be a slower process, but although the cause of irritation would then have been removed, it would not do to leave the matter entirely to nature. Warm vaginal injections, of from five to fifteen minutes' duration, should still be kept up, and complete rest should be enjoined at the time of the menstrual periods. In addition, tincture of iodine should every week be painted over the whole roof of the vagina by way of mild counter-irritation, and the continuous current of the galvanic battery should be locally applied two or three times a week. The latter, as I have often mentioned to you, sometimes accomplishes a great deal in these troublesome cases. While the constant current does not relieve the engorgement itself, the latter I believe to be due to a large extent

to nervous derangement, and this electricity has a beneficial effect upon. The whole treatment may be described as of an "alterative" character, and in order that it can be carried out fully and faithfully I should recommend by all means that the patient should enter some such institution as the Woman's Hospital, and remain there for at least three or four months.

CASE III. OPERATION FOR LACERATION OF THE CERVIX IN A CASE OF PROCDENTIA UTERI.

You will now have an opportunity of witnessing one of those operations which I told you previously it would be impossible for me to show you at this clinic, on account of the difficulty of any considerable number of individuals seeing anything through a speculum; but this is a very exceptional case, since I can perform the operation for the repair of laceration of the cervix while the uterus is entirely outside of the body. Such being the fact it can be seen in a more or less perfect manner by even such a large class as that now before me, and I may premise that the operation is to be performed in precisely the same way as if it were done through a speculum at the upper part of the vagina. As I have provided a carriage in which to take the woman home, she will incur no risk in thus having it done at the college.

The patient now being brought in, thoroughly anesthetized, you can perceive that the uterus has been kept up in very good condition by the pessary which she has worn during the week that has passed since she was here, and when I now permit the organ to descend by removing it, I think you will all be struck by the marked improvement which has resulted simply from her wearing the instrument for a week. The uterus has, apparently, diminished in size to the extent of one half, and the edges of the lacerated cervix are much less everted and swollen than they were a week ago to-day. All of you, however, I think, can perceive the rent, which is of quite an extensive character. You no doubt remember the rough simile which I used in describing the nature of the operation for the repair of laceration of the cervix. It is just as if you were going to form an adhesive union between two fingers, for instance, and, in order to accomplish this, you would first denude the surfaces to be united, and then secure them in apposition by means of sutures.

I think it best to begin at the lower part here, and having pared the two surfaces by means of the scissors, I plunge the needle, threaded with silk, in on one side, carry it across, and bring it out on the other side. A silver wire suture is then drawn through to take the place of the silk, and care having been taken to see that the parts are in perfect apposition, I twist it by means of the little instrument I show you here, and my first suture is completed. The other sutures are put in and secured in the same manner, and now you perceive that I have completely closed this portion. I next proceed to the upper part, and, having pared the surfaces, bring them into apposition, and put in my sutures as before. Finally, the laceration on the other side of the cervix is treated in the same way, and then the operation is finished. Most of you can now see, I think, how perfectly this lesion, caused by parturition, has been removed. The cervical canal has not been interfered with by the operation, and there is not the slightest danger of its becoming closed or rendered smaller, for the reason that its walls have

not been denuded, and there is, therefore, no danger of an adhesive union taking place between them.

The operation is a prettier one, and requires the exercise of more skill, when the cervix is in its normal position instead of outside the body, as in this instance, since it is then impossible, of course, to use the fingers to such an extent as I have done here. It also demands a perfect familiarity with the use of Sims' speculum on the part of the operator. This is a comparatively trivial operation, and yet it does a great deal towards the cure of such a case as this. The patient is now to be kept quiet, and injections of carbolyzed water should frequently be made through the speculum. At the end of about nine days the sutures will be removed, and the woman will then be ready for the next operative procedure. The second step in the case will be the taking of "a gore," so to speak, in the anterior wall of the vagina by the operation known as elytrorraphy, and then the final operation will consist in the restoration of the destroyed perineum, after which I think the case can be discharged perfectly cured. These two latter operations are, of course, of too serious a character for me to think of performing them here at the college, but I shall hope to have the pleasure of affording some of you, at least, the opportunity of witnessing them elsewhere.

Original Articles.

A CASE OF ABSCESS OF THE LUNG.¹

BY C. E. INCHES, M. D.

APRIL 14, 1881. Visited for the first time B. A., aged eighteen years, who, from the report of his mother, has been a very hard-working young man, having during the past three months, in addition to other work, spent a portion of each day in a fishmonger's, where it was necessary to have the temperature nearly as low as the outside air. During all this time he suffered from constant headache and also from constipation and malaise. There was no cough. His habits appear to have been good with the exception of excessive smoking with constant spitting.

A week ago, on April 7th, Fast Day, he visited the theatre with some male companions and in scrambling hurriedly over the seats to obtain a good place he fell, striking his right side against the back of a seat. He described the blow as very severe, felt ill, and the pain and distress grew rapidly worse. At the termination of the performance he went home to bed where he has remained since, now one week. According to the statement of his mother, a very intelligent woman, he became suddenly very ill the night of the 7th; vomited constantly after eating or drinking; was in a high fever; had great pain in head, epigastrium, and right side; he also suffered from wakefulness, delirium, cough, and loss of appetite. As far as can be learned this was the history of the case during the week. A physician had been called in who pronounced it a case of typhoid fever and recommended that he be sent to the hospital for treatment.

At my first visit I found the patient in bed lying on his back, which was raised to an oblique angle. He had suffered a great loss of strength. The seat of the injury from the fall, as pointed out by the patient, was

¹ Read before the Boston Society for Medical Observation, June 6, 1881.

over the epigastrium and below the right breast, principally about the sixth and seventh ribs, and there was pain in breathing and coughing and on pressure, but a most careful examination failed to detect any deviation from the normal position of the bones at this place. Percussion over them and in the vicinity showed dullness, and on auscultation there was diminished respiration with crepitant râles. The abdomen was flat with no rose rash and there was no gurgling in the iliac fossa. Headache severe; intelligence good; stomach less irritable, though he often vomits; pulse 120, but character not bad; temperature not taken, but to the hand felt hot.

April 16th. No apparent change in any of the symptoms, except that the vomiting has ceased and he is now able to take a considerable amount of milk; pain severe in epigastrium and right side; morning temperature 101.2° F. in right axilla.

April 18th. Reports himself as feeling better; his eyes are bright and he looks intelligent, though there is delirium at night; morning temperature 100° F. in right axilla; tongue thickly coated except a narrow raw-looking strip around border.

April 20th. He appears better to his attendants and states that the pain in right side is less severe, and is now of a dull heavy character when he has one of his rather numerous paroxysms of coughing.

May 2d. Has not been seen since April 20th, twelve days. His attendants report that he improved slowly until yesterday, when his cough became severe and distressing; his appetite, which had been good, was lost, the delirium returned at night and there was a recurrence of the severe pain in side; respiration 32; pulse 96; no dyspnea.

May 5th. Was summoned early in the morning, the patient being reported as much worse, and found the patient in a half-recumbent posture in bed, pale, exhausted, coughing at times violently, and raising large mouthfuls of greenish pus mixed with a rather small proportion of mucus of the same color and having a fetid odor; on inquiry I found that on the previous evening, feeling somewhat oppressed in breathing, he blew his nose forcibly and that over a pint of a foul-smelling fluid poured from his mouth without vomiting, and that during the night he continued to raise large mouthfuls of the same fluid, which was of a most sickening odor. Percussion showed no tympany, but on the contrary marked dullness over right back from the fourth rib down. Along the abdominal border of the chest the note was clear. On auscultation crepitant and subcrepitant râles were heard over the second and third lobes, increasing in the latter. The intercostal spaces retain their concavity. There is not now nor has there been at any time jaundice. Respiration 30; pulse 96, weak and fluttering; no febrile action, the skin quite clammy; no abdominal swelling. An increase of sputa is reported, some of a reddish hue, and in the most recent several small clots were noticed.

May 6th. Patient perspiring freely, sputa profuse, of a green color and frothy, and streaked with blood; no sleep on account of constant and severe cough and pain; tongue is clearing and moist; respiration 27; pulse 96.

May 7th. For the first time the sputa has been kept there being over twelve ounces for the past twenty-four hours. It is all of a greenish color, moderately fetid, none dark-brown or blackish, but some of a reddish color. There is still dullness on percussion and

natural resonance cannot be found in the right chest. Over the lower part of left lung are heard now bronchial râles, though heretofore nothing abnormal was observed except at times exaggerated respiration. Patient cannot sleep; cough and pain very severe; pulse 98, small.

May 8th. Has slept a little during the night, which is the first since the discharge of pus on the night of the 4th. The region of the injury is still sensitive on pressure; sputa eleven ounces during the twenty-four hours; respiration 32; pulse 108; profuse perspiration.

May 9th. The chest was measured this morning and the two sides were found about equal; he slept six hours last night, though his rest was disturbed by moans and mutterings; the right hand and arm have been swollen and useless for several days, but he is able to use them this morning; pulse 88, weak and intermittent; sputa over ten ounces.

May 10th. Was quiet yesterday until night, when cough commenced and continued until five A. M., with an expectoration of a pint of sputa containing at least an ounce of blood. Early in the morning he was so exhausted that a fatal result was feared from inability to raise the secretion, but at ten A. M. he seemed brighter and stronger. The body is bathed in perspiration and there is a miliaary eruption; pulse 99, feverish, not intermitted; amount of urine increased.

May 11th. Passed an easier night; sputa, eight ounces, odor not remarkable for several days; respiration in left lung rather coarse but nowhere deficient; pulse 80; tongue moist and clear; appetite good.

May 12th. Has slept six hours; cough less; sputa six ounces; pulse 78; urine normal in appearance.

May 16th. General appearance much improved; breathing in left lung vesicular; respiration quick; appetite excellent; sleeps well, as cough has diminished; pulse 84.

May 23d. Sits up in bed, and attempted yesterday to get out of it, but legs were unequal to the task; dullness over right back diminished; on auscultation bubbling of fluid was found, subcrepitant râles, and at different places what appears to be vesicular breathing can be distinguished; cough is less; sputa three ounces; his appetite, which has improved recently, is now enormous; pulse 96; tongue clean; respiration 25.

Treatment. In a case of this description, being called a week after the beginning of the attack, and after the febrile period was nearly over, active efforts were in order to reduce it by cold water, quinine, etc., and there was little else to be done except to quiet the pain and support the strength. The former indication I was not very successful in meeting, as I did not feel justified in giving to a very considerable extent opium or chloral, especially after the bursting of the abscess. At that time the secretion was excessive, and was raised with difficulty, and it was not justifiable to quiet the cough, the active agent of its removal. The diet was principally sherry wine and milk, but not taken together. At the worst periods he often drank during the twenty-four hours twelve ounces of the former and twelve glasses of the latter. The right side was constantly painted with the tincture of iodine, and was soon blistered and kept so. This, though beneficial by exhalation of the vessels of the skin, perhaps conferred a greater benefit on the mind of the patient, who was enabled to refer some of the pain of the diseased lung to his blistered side. The body was sponged

frequently with alcohol and warm water, and the bowels kept open on alternate days by enemata unless they moved naturally.

This was probably a case of croupous pneumonia in the first instance. The sudden seizure the night of the 7th of April with the symptoms then and afterwards, as narrated by the family, the subsidence of acute symptoms about the eighth day, the time of my first visit, and the gradual convalescence from that time until the formation and breaking of the abscess again endangered the patient's life, are quite compatible with such a diagnosis. He was a sick man at the time of the injury at the theatre, and the disease would have exploded whether that had happened or not, even if the ragged edge of a broken rib had been forced into the right lung. The only stress to be laid on this injury is that the constant pain and tenderness on pressure, lasting between four and five weeks, over the sixth and seventh ribs, in front, render it possible that there was contusion of the lung, it being inflated at the time of the accident, and from this contusion sprang a localized pleuritis, which at no time was anything else but local, since from the patient's account, whose head was always clear in waking hours, no history of pains spreading and radiating over whole of right chest was obtained, and, moreover, the contused lung tissue might have been the nidus of the subsequent abscess. It is true, of course, that local pleuritis and pulmonary abscess are sequelae of croupous pneumonia. This abscess was situated in the third lobe of the right lung, an unusual place, since the usual recorded habitat is in the first, but the first in this case was not affected except by bronchial râles, probably due to a great amount of secretion coming from below. I regret not finding accounts of the size of such abscesses judged from their contents. This one must have been very large to contain all the pus coming from it. The family insist that during three weeks he spat a gallon of mucus-pus, and when the abscess broke their estimate was two quarts. Even to me, knowing how much more in quantity a fluid appears when spread upon bed-clothes, towels, etc., the amount was surprising. I know there is difficulty in thinking such a cavity could exist in the lung sufficient to allow of so great a discharge as that of the 5th of May. With the subsequent abundant daily discharge there is less trouble on account of the well recognized secreting power of the walls of a pulmonary cavity. An empyema might, by breaking through the pleura pulmonalis, have accounted for it, but too many symptoms are adverse; these were: absence of general pain in the affected side; of dilatation either from effusion or pneumo thorax, later; the dullness which did not alter on change of position, though percussion, to verify this, was not tried till some time after the bursting of the abscess; the want of unnaturally loud and deep resonance on percussion, such as would have existed had the air gained admittance through a rent of the lung into the pleural cavity, which it always does; neither, which is about as invariable, was there collapse with cyanosis. Was it pulmonary gangrene? There were no dark-brownish or black sputa. The fetor, which soon disappeared, never possessed a true cadaveric odor, but was similar to that of the contents of a large and neglected abscess elsewhere, nor was it manifested in the breath; and there was an absence of symptoms of systemic poison, as would be likely to arise were so large an extent of lung tissue gangrenous.

The case is too recent to admit of decision as to whether this was acute tuberculosis. There is, however, no heredity in the case. The headache and malaise during the winter may have been due to overwork — and perhaps, also, to poisoning by nicotine, as he was an inveterate smoker — rather than typhoid-fever poison.

September 21, 1881. Re-examined to-day, and found slight diminution of respiratory murmur back from sixth rib downward; no râles, also slight loss of resonance on percussion in same locality; no retraction of right side of chest (three measurements); general condition excellent; has been at work for two and one half months.

RECENT PROGRESS IN ORTHOPEDIC SURGERY.

BY E. H. BRADFORD, M. D.

RESECTIONS OF JOINTS AND ANTISEPTIC DRESSINGS.¹

ALL reference to the subject of antiseptic surgery is of particular interest at present, and the opinion of a surgeon of so extended an experience as Ollier upon the subject is of unusual value, as his judgment can embrace a series of successful results before antiseptic surgery was introduced. He claims for the advantages of "Listerism" that (1) a successful result is to be expected with greater certainty under antiseptic treatment than without, as the septic processes, leading to osteomyelitis and denudation of bone, can thereby be prevented. (2.) The reparative processes of the bone and of the periosteum in subperiosteal resection is greatly fostered by antiseptic measures. (3.) Secondary changes in the muscles can be better avoided in the new than in the old surgical method.

The writer, however, does not advise complete closure of the wound after antiseptic resection.

THE QUESTION OF AXILLARY OR ISCHIATIC SUPPORT IN JOINT DISEASES OF THE LOWER EXTREMITY.²

Dr. Judson states his decided preference for a splint with ischiatic support for the following reasons: Locomotion with crutches requires the use of both hands, while both are free when the splint is worn; the hip-splint is always present, while crutches may be temporarily discarded, and also the ischiatic region is better adapted anatomically for a firm resistance than the axilla.

The persistent and long-continued use of crutches was first recommended by Mr. Edward Ford, and later by Mr. Brodie, and an ingenious apparatus of Mathieu was devised on the principle of axillary support (practically modified crutches).

Dr. C. F. Taylor advised, in 1867, the use of crutches, with an elevated sole on the well foot, a method of treatment which has been more recently advocated by Dr. Hutchinson, of Brooklyn, by Drs. Wyeth and Stillman, of New York, Dr. De F. Willard and Dr. Levis, of Philadelphia, and crutches form an important feature in the treatment advised by Mr. Thomas, of Liverpool.

Ischiatic support was apparently first applied in the construction of orthopedic appliances by Ambrose

¹ Ollier. *Revue mensuelle de Chirurgie*, December, 1880.

² Judson. *New York Medical Record*, July 2, 1881.

Paré; in modern times it has been tried by Bonnet, Martin, Bigg, Henry G. Davis. The first really efficient apparatus devised according to this principle is that described by Dr. Andrews, of Chicago, in 1860; this was subsequently modified by Dr. David Prince.

Dr. Davis's splint was, however, modified by Drs. Sayre and Taylor. The splint used by the latter is the one preferred by Dr. Judson as the decidedly most efficient.

An additional advantage of ischiatic support in the treatment of chronic joint affections is that it enables the continued employment of traction, the value of which has been considered in another paper by Judson.¹ Admitting that it is improbable that traction or extension (as it is ordinarily called) can exert any appreciable "distraction" or separation of the femur from the acetabulum, and that it is doubtful whether reflex muscular spasm incident to hip disease can be efficiently controlled or tired out by "over-stretching" by means of adhesive plaster applied over the integument or soft parts, the writer claims that as a means of simple fixation traction is of great value. This fact was recognized by Desault in the treatment of fractures. In applying the principle to the treatment of hip disease, he claims that the ordinary extension splint retards and arrests motion, so that in walking the chief motion is at the lumbar region of the back. A hip-splint so applied does not secure absolute immobility, but it does fixation, or a reasonable degree of immobility. This fixation, he claims, is sufficient to allow the reparative process to take place.

ANCHYLOSIS OF THE HIP-JOINT.²

The writer describes an apparatus which he has found useful in correcting the deformity after division of tendons and muscles or cicatricial tissues (namely, the adductor longus, tensor vaginae femoris, rectus, sartorius), followed by forcible rupture of the more deeply-seated adventitious impediments to free movements.

It is designed for the purpose of thoroughly fixing the pelvis while the limb is being brought down to the line of the body. The apparatus consists of a block of wood carved so as to accurately fit the buttock of the patient, who is secured by heavily-padded straps passing over the ilia. At each side of the block is a narrow bar of steel extending to the knee, where a padded steel band grasps the femur. In this bar two ratchet screws are inserted, which permit of motion of the bar in the direction of abduction and adduction, flexion and extension.³

OSTEOTOMY FOR GENU VALGUM.

Dr. Poore⁴ prefers Macewen's operation to that of Reeves after a personal experience with both, because the danger of opening the joint is less in the former than in the latter. Macewen's method, as is well known, consists in the division of the femur by a chisel inserted just above the joint on the outer side. Poore is inclined, however, to think that some of the precautions used by Macewen are unnecessary.

One of the operations was done with the strictest antiseptic precautions; sixteen were done without thorough Listerism; in one of the latter only was

there any considerable suppuration, and in only one case did the temperature rise above 99.5° F. In this case it rose to 102° F., for one evening, without known cause, without, however, any injurious results.

Dr. Poore immediately after the osteotomy applies a plaster-of Paris bandage, and cuts a fenestrum over the wound three days later. The pain after the operation is slight.

In the discussion which followed this paper⁵ Dr. Weir thought that Delore's method of forcible straightening deserved a better acceptance in this country than it had yet received. In young patients, before the union of the epiphyses, the operation is particularly indicated, but beyond the years of thirteen and fourteen it is to be neglected. Mikulicz, in experimenting, ruptured the external lateral ligament in cadavera nineteen to twenty-three years of age ten times in nineteen cases. Santi ruptured it nine times in twelve experiments. In living adults or adolescents considerable weakness of the joint has followed the operation.

In two of Delore's cases, on autopsy (one being seven and the other three years of age), death occurring one on the second and the other on the thirtieth day after the operation, separation was found to have taken place at the epiphyseal junction.

Dr. Sands described Colin's osteoclast, devised for the treatment of genu valgum. This consists of three wooden stocks which embrace the middle of the leg, the middle of the thigh, and the knee; the latter is movable transversely, and the power is applied by means of compound pulleys acting on the end of a long steel lever. The limb is placed so that it is impossible for it to rotate, and the force is applied gradually. In two cases operated upon Dr. Sands found the result excellent in one, imperfect in the other; in this, however, the operation was repeated. In the cadaver the lesion produced by the instrument was found to be a partial separation along the epiphyseal junction without rupture of the ligament.

CLUB-FOOT. OPERATION OF DIRECT INCISION.⁶

Dr. Phelps, of Chateaugay, reports this operation as having been successfully tried by him in a case where tenotomy alone did not suffice. An incision was made across the sole of the foot, dividing all the tissues resisting.

THE TREATMENT OF PELVIC ABSCESS IN HIP DISEASE.⁷

Habern classifies these abscesses as follows:—

- (1.) Those which are dependent upon disease or perforation of the acetabulum.
- (2.) Those from the rupture of the capsule in purulent coxitis on the inner and upper insertion. The pus passes over the pubic bone into the fossa ilia.
- (3.) That form which results from an extension upwards of an abscess formed between and beneath the adductors, and spreading along the ilio-psoas muscle into the pelvis.

(4.) Para-articular abscesses without communication with an inflamed joint.

The first form is, according to the writer, an exceedingly common one. This is due to the frequency of primary osteal disease of the acetabulum, an affection which is much more common than has usually been

¹ St. Louis Courier of Medicine, May, 1881.

² Richardson Brown. Boston Medical and Surgical Journal, Jan. 2, 1881.

³ For a fuller description of the apparatus the reader is referred to the author.

⁴ New York Medical Record, August 13, 1881.

⁵ Loc. cit., page 187.

⁶ New York Medical Record, August 13, 1881, page 169.

⁷ Centralblatt f. Chir., April 2, 1881.

supposed. Out of one hundred and thirty-two resections of the hip-joint at Volkmann's klinik, in fifty a caseous focus of the acetabulum was found (with a sequestrum in thirty-one). In twenty-three there was a focus of the femoral head, neck, or trochanter; in seven foci in both; in twenty-nine such a destructive condition that it was not possible to state the site of the primary disease; in twenty-three cases probable evidence of primary synovial disease.

This variety may extend either directly into the rectum or at the side of the intestine pointing in the ischio-rectal region or may spread downward on the posterior side of the thigh, in some cases as far as the knee. Secondary disease of the acetabulum may also occasion pelvic abscess.

RESECTION OF THE HIP-JOINT IN COXITIS.

A committee of the Clinical Society of London were appointed to consider this subject, and the report may be said to represent the surgical opinion of London, as to the ultimate results of operative interference and from conservative treatment. The number of cases of excision investigated was three hundred and twenty. The percentage of mortality was forty per cent., that of recovery forty-two per cent. In fifteen per cent. death followed directly from the operation; in thirteen per cent. from phthisis; in six per cent. from albuminoid nephritis; in four per cent. from other causes not connected with the affection of the hip. The treatment of those who recovered lasted one and three fourths years, the duration of the affection three years, and the average shortening of the limb was two and three fourths inches.

The mortality of the suppurative cases treated conservatively was thirty-three per cent., the percentage of cure was forty-two per cent. Death occurred in twenty per cent. from hip disease, from phthisis nine per cent., from various causes three per cent. The duration of treatment of those who recovered was two and one half years, of those who died one and one half, and the duration of the disease of those who recovered was four years. The amount of shortening in cases with a good result was one and one fourth inches, in average cases three and one fourth inches; absence of some shortening was rare.

In non-suppurative cases the cures were sixty-nine per cent. of the whole, twenty per cent. remained incomplete, and ten per cent. died. The course of the affection was three years.

The committee considered the following as indications for resection:—

- (1.) Necrosis of the head of the femur and the separation into loose sequestra.
- (2.) Firm sequestra of the head of the femur, the neck, or the acetabulum.
- (3.) Extensive caries of the femur or pelvis with fistulae.
- (4.) Pelvic abscess with disease of the acetabulum.
- (5.) Old chronic synovial suppuration with disease of the cartilages of the acetabulum.
- (6.) Luxation of the femur on to the ileum with chronic suppuration and fistulae, a condition indicated by early suppuration and general symptoms.

Resection is also indicated in albuminoid degeneration, in cases with a great deal of suppuration and continued loss of strength in spite of care, rest, and also in pelvic suppuration for the purpose of better drainage.

Pelvic abscess can frequently be recognized by palpation from the rectum.

The result of excision is usually greater mobility than after conservative treatment, and the gait is much less certain, and more limping.

Resection should be done below the large trochanter only when the latter is carious, and great attention should be paid to the preservation of the insertion of the glutei,¹ which should never be cut across, but always along the course of the fibres. In pelvic disease, however, the trochanter should be removed for better drainage.

König, of Göttingen,² looking at the matter of early resection from a German standpoint, substantially agrees with the opinion of English surgeons. Considering fungous disease of the joints as "joint tuberculosis," and as generally the result of localized disease of the epiphyses (*Herderkrankungen der Gelenkenden*), and admitting that early resection may be of value as the best preventive against general tuberculosis, he asks the question whether this may not be effected by other means without destruction of the joint, that is, by incision and scraping of the tuberculous foci in the bone without absolute resection. The question which a surgeon has to answer before deciding on resection is whether the protection of the patient's general condition demands the sacrifice of the joint. He claims that a large number of patients with undoubted tuberculosis of the joint get well without any generalization of the disease, and also that by statistics it has been satisfactorily shown that the danger of general tuberculosis is not greatly lessened by resection.

He reports a number of successful cases resulting in a useful limb, where he cut down upon the bone suspected as affected, tracks the fistula into the bone, and with the chisel and sharp spoon thoroughly removes the affected bone without destroying the joint.

TREATMENT OF SEVERE CLUB-FOOT.³

When the removal of a portion of bone from the tarsus is regarded necessary for the cure of club-foot, the choice of the method of operation is not at present an easy one.

Ried, in a recent article,⁴ stated his preference for removal of the astragalus over the excision of a wedge-shaped portion of the tarsus, for the reason that the shape of the foot in the result would be better after the former than the latter operation, but he admitted that the question was still to be settled by future clinical facts.

Wagner reports seven operations by Lücke, of Strasburg, all of which were successful. These were all performed in a variety of ways, and the conclusion formed is that excision of the astragalus is the preferable method, from which the best result is to be expected in the shortest time. In case, however, of partial bony ankylosis in the tarsal bones (a condition rare among children) excision of a wedge-shaped portion of the tarsus is to be preferred.

Excision of the os enuoid alone is rarely sufficient for the correction of the deformity. In combination with removal of the head of the astragalus in certain cases a good result may be expected.

Removal of the head of the astragalus and also of

¹ British Medical Journal, May, 1881.

the tip of the fibula gave an excellent result in the hands of Lücke.

LOCATION, AGE AND SEX IN CARIES OF THE SPINE.¹

The writer premises with the statement that the apex of the spinal projection may be regarded as corresponding with the point of maximum vertebral destruction. In three hundred cases he found that every vertebra was diseased except the first cervical, where disease is not readily recognized. There may be said to be three centres of maximum liability: First at the sixth and seventh cervical; second, about the eighth dorsal; and third, at the second and third lumbar. The frequency of disease is greatest in the dorsal region, and nearly as great in the lumbar, but less frequent at the cervical.

The points of least liability to the disease are from the first to the fourth dorsal and the eleventh and twelfth dorsal, besides the two extremities of the spinal column.

These facts the writer explains (assuming that traumatism is the chief inducing cause of Pott's disease) by showing that the regions of greatest liability to disease are the regions most exposed to jar. The dorsal convexity is the most vulnerable region of the spine, not only because of its mechanical relation to the curve of the spine, but also as owing to its connection with the ribs and sternum it is more liable to receive a jar communicated from blows than the cervical or lumbar region. The pressure, however, of the superincumbent mass neutralizes this immunity in the lumbar region.

The upper dorsal region is to an extent protected by the arms and scapula, which, not being fixed to the spinal column, break the jar of a fall. The upper lumbar may be regarded as being placed at the point of the "natural hinge" between the upper and lower halves of the body.

In regard to age, in 375 cases 226 were under five years when the disease began; 68 were between five and ten, 24 between ten and fifteen, and so on, the number diminishing in each decade. The disease began in 77 cases before the second year. Out of 412 cases 235 were boys, 177 females.

HYPNOTIC CONTRACTURES.²

Among other phenomena of the state of hypnotism those of contracture have recently been studied by Charcot. This condition is easily produced in a hypnotized patient by mechanically stimulating the tendon, the motor nerve, or the substance of the muscle. The contracture is very firm. When the hand is the part affected it cannot be opened by any force; it relaxes, however, by stimulating the opposing muscles. If the patient is awakened while the contracture persists the contracture may disappear or may persist. If the latter is the case irritation of antagonizing muscles will not cause relaxation of the contracture unless the patient be again hypnotized.

If the limb is made anæmic by an Esmarch bandage before the patient is hypnotized the contracture cannot be made to take place until the circulation of the blood be restored by loosening the bandage.

TRANSPLANTATION OF BONE.³

MacEwen has recently succeeded in transplanting

bone in a case of necrosis of the humerus. Two thirds of the shaft in a child four years old had been removed fifteen months before and there had been no replacement nor bone formation. Small fragments of bone were inserted in a groove made in the soft tissues of the arm where it was supposed the shaft should be. These fragments of bone were those which had been removed from patients with curved tibiae. The result was that solid new bone was developed, the new portion united firmly to the old. The wound was kept during the process of plantation and bone culture perfectly aseptic.

Mr. Macnamara, of London, has recently made a similar attempt in reproducing bone, but the result has not yet been reported.

Hospital Practice and Clinical Memoranda.

MASSACHUSETTS GENERAL HOSPITAL.

CASES IN THE SERVICE OF DR. J. COLLINS WARREN.

REPORTED BY C. B. WITHERLE, M. D.

COMPOUND DISLOCATION OF FORE-ARM.

A. C., a boy of eleven, entered with a dislocation of the fore-arm backwards. The condyles of the humerus projected through a linear wound at the bend of the elbow. The coronoid process of the ulna was fractured. The injury had occurred about four hours before entrance.

The dislocation was reduced, and the joint thoroughly syringed with a five per cent. solution of carbolic acid. A drainage tube was inserted, and a Lister dressing applied.

The temperature was 101° to 103° F. for five days after the injury, and then fell to normal. There was a slight discharge of pus from the wound, and considerable swelling about the joint. The active inflammatory symptoms subsided after the first week. The wound had nearly healed four weeks after the injury, and the patient was discharged wearing a splint and Lister dressing. He returned for examination eight weeks after the injury. The wound had then entirely healed, and there was motion in the injured joint to about half the normal extent. The patient was again seen six months after the accident, and the joint was found to be perfectly normal both in motion and strength.

COMPOUND DISLOCATION OF ASTRAGALUS.

Seven weeks before entrance the patient, a man aged twenty-eight, fell from an embankment, and received a dislocation of the right astragalus. The bone projecting from a large wound on the outer side of the ankle. The attending physician reduced the dislocation, and put on a plaster bandage extending to the knee. A window was left over the site of the wound. On entrance to the hospital the bandage was removed. There were found several sinuses on the inside of the ankle, and an abscess on the inner side of the leg, extending nearly to the knee-joint.

Examination under ether showed that the entire astragalus was necrosed. A sinus on the inside of the joint was dilated and the astragalus removed through it. The abscess of the leg was laid open from end to end. The leg was then placed on a Goodwin splint, with the knee bent. Oakum was used for dressing,

and the wounds syringed daily with carbolic acid. The patient's condition, both local and general, steadily improved from this time. The wounds had entirely healed ten weeks after the operation. A dextrine bandage was then applied, and the patient allowed to use crutches. The bandage was worn for three months. During the two months since its removal the patient has worked at his occupation of clerk in a grocery store, and uses a cane only when he takes a long walk. There is no motion at the ankle-joint.

UNUNITED FRACTURE OF LEG.

In April, 1878, J. S., a man aged fifty-five, was run over by a cart, the wheels passing over both legs. On entrance to the hospital there was found a Pott's fracture of the right ankle and a simple fracture of the left leg, just below the knee, with severe comminution for a distance of three inches. The fractures all united without unusual delay except at one point in the left leg. The injury was thus converted into a simple fracture of the left tibia and fibula. The bones at the point of non-union were wired in May, 1880, but failed to unite. The patient was discharged wearing a dextrine bandage. He reentered in October, 1880, with no signs of union. The fracture was cut down on with antiseptic precaution, the periosteum retracted, and the ends of the tibial fragments cut off so as to leave square surfaces. These surfaces were then brought together with a wire suture. The fragments of the fibula were not interfered with.

The patient made a good recovery from the operation. The wire was removed in January, 1881. At this time the bone at the seat of the fracture was not united, though there was considerable progress towards good union. A dextrine bandage was applied, and the patient allowed to use crutches. In July, 1881, the bandage was removed, and the tibia found firmly united.

PERINEPHRITIC ABSCESS.

D. B., a man aged forty, entered with very severe pain in right lumbar region, of about two weeks' duration, constant and steadily increasing. He had had symptoms of stricture for about a year and four months before entrance, his urethra had been dilated, according to his statements, from about No. 4 to No. 12 (English) measurement. He had still a slight gleet. The urine passed freely, and contained nothing abnormal except a little pus, probably from the urethra. The temperature the evening of entrance was 103° F.

One week after entrance the patient thought there was a slight swelling in the right lumbar region, but this could not be distinctly made out by any of the several surgeons who examined. The fever and pain were, however, steadily increasing, and it was decided to operate. Antiseptic precautions were observed. An incision about three inches long was made parallel to the edge of the quadratus lumborum. A Bigelow-Sims dilator was then pushed through the lumbar muscles, and on being spread open pus immediately flowed, about eight ounces being discharged. A drainage tube was then introduced, and a Lister dressing applied.

Recovery was slow, but was interrupted but once, then by the too early withdrawal of the drainage tube. The wound closed entirely three months after the operation. At this time a slight contraction of the urethral meatus was divided, after which a No. 16 (English) sound passed easily into the bladder. Five months after the operation the patient was able to resume

work, having had no return of the inflammatory symptoms.

Dr. Warren finds that the use of the sinus dilator simplifies many operations performed for the purpose of reaching pus. An abscess of the prostate pointing in the rectum was opened in this way without the use of the knife. In making the permanent opening in empyema a fold of skin may be pinched up at the desired point and divided with the knife, the dilator is then thrust through the intercostal muscle and pleura, and the opening thus made is spread to the desired width.

New Instruments.

DOUBLE IRRIGATION, INJECTION, AND DRAINAGE TUBES.¹

BY HENRY O. MARCY, M. D.

IN the recent progress of surgery, thorough drainage of wounds and suppurating cavities is considered scarcely less important than even their antiseptic treatment.

The instruments for which I ask consideration, are designed in a large degree to aid, under certain difficult conditions, a somewhat similar purpose.

There is no novelty in double tubes, the value of which has long been appreciated by the profession, but, so far as known, they have been hitherto constructed of metal or other stiff material, and on this account their utility is greatly lessened.

Since the curing of rubber in glass moulds, thus giving such perfection of finish and durability to its surface, the rubber catheter has in a large measure, for most excellent reasons, supplanted the use of the older and more expensive instruments. It seemed to me possible to furnish a tube of various dimensions, double through its entire length, and of equal beauty of finish.

After experimentation in this direction, the Davidson Rubber Company, of Boston have succeeded in preparing for me tubes varying in measurements. They are French scale, 18, 22, 25, 27, 35, 40, and in length from fourteen to twenty-four inches.

The thought which most prominently prompted their usage was to obtain, in any cavity, not only a thorough cleansing from its contents, the removal and destruction of septic material, but especially to give to its surfaces the results caused by the secondary effects of heat and moisture, results well known to the profession in the external use of poultices, the vaginal douche, etc.

This, for some years, we have been accustomed to make available by the use of double metallic tubes, as, for example, the intra-uterine douche, and in cystitis. The double canula, known widely as Dr. Bixby's

double tube, is by far the best hitherto met, and in the use of which was felt the great desirability of a similar effective instrument which should be flexible. However advantageous, such instruments cause pain and suffering, while they are more or less difficult and dangerous of introduction.

With the double rubber tubes these disadvantages are almost completely avoided. The applicability of such tubes readily suggests itself as wide and varied.

In diseases of the bladder the No. 18 is sufficiently small to enter the adult male bladder unless the passage thereto is constricted. Even with a considerably enlarged prostate it enters quite easily, and the benefit of the continuous current is very speedy and marked.

The relief comes, not only from the washing out of mucus and decomposing urine and the destruction of bacteria, but, continued, as has been my habit, for one half hour, night and morning, at the temperature of about 100° F., the congestive thickening and vascular supply of the mucous membrane are greatly diminished, the prostatic irritability is largely held in control, and permanent improvement ensues.

In hæmorrhage from ulcerations or other processes the results are even of greater value. In illustration I cite briefly the following case: Mrs. T., aged sixty-four, always well until within one year. Noticed trouble in passing water about six months since. Micturition frequent and painful; sediment thick and ropy. About a month before consultation began to pass bloody and coffee-colored urine, and clots were in the deposit. Despite every attention of the family physician she grew steadily worse, until at visit, and for two weeks preceding had been in bed. Was emaciated, very anæmic and feeble. It was apparent the patient could not much longer sustain the continued loss of blood. A careful examination revealed no evidence of renal complication, but there was a contracted bladder, with thick walls, a roughened surface, and hæmorrhage was increased after examination. Retained catheter for a considerable period to allow of complete rest of organ, but without benefit. Used hot-water current one hour without lessening the hæmorrhage, although it gave no suffering; then arranged for its continuous use at a carefully regulated temperature of 100° F., slightly carbolyzed, which was continued forty-eight hours, after which the bladder was allowed to be emptied voluntarily. There was no return of the hæmorrhage; the urine remained free from pus and mucus. Rapid convalescence followed, which was continued for more than six months.

In acute cystitis the results have been even more gratifying.

In the large class of cases, where the uterus has become the receptacle of septic and decomposing materials, the tubes have proved of great value. After childbirth, I have found the larger sizes the most convenient and advantageous. Their introduction is easier, as a rule, and the clots and *débris* come away with greater readiness. The intra-uterine douche under such circumstances has appeared to me of such service that it may challenge comparison in beneficial results with the vaginal douche, as recommended by Dr. Emmet, which has been found of such marked advantage in uterine and pelvic inflammations, that already it has generally won the confidence of the profession. Hitherto intra-uterine injections have been usually considered as dangerous, because a free return current has not been secured, and, on this account, even in the most marked

¹ Read before the American Medical Association, May, 1881.

cases of septic poisoning from decomposing materials retained in the uterus, the removal of the cause is undertaken only exceptionally. Guided by the dogmatic conservatism of the past, and the fear of patent Fallopian tubes, many a patient has been allowed to die.

In narrowing of the rectum from inflammatory conditions of the pelvic organs, the relief and benefit have been in every case most marked. In these instances the tube enters the colon, and the water is left, without strain upon the intestinal wall, at a point above the inflamed or involved part; not only is the large intestine emptied of its gas and contents, and the tenesmus and pain removed, but the poultice-like effect of the continuous current is very efficacious in reducing the congestive and inflammatory processes of any of the pelvic organs.

The comfort and advantage have been equally marked after various pelvic surgical operations, where gaseous distentions are often so troublesome. In one case, where I removed the uterus and both ovaries, this procedure, commenced upon the second day, was not only painless but of such service that it was continued until convalescence was assured.

The use of the double current through such a soft flexible tube renders it easy and effectual to cleanse the pleural cavity in empyema, to wash out long, irregular sinuses, deep gun-shot wounds where necrosis of tissue must follow the track of the bullet and frequently shreds of clothing, small pieces of bone, etc., are retained.¹

In nutritive enemata I have felt considerable gain has followed the introduction of the fluids thus high in the transverse colon, and can but recommend their use for further trial. The subject of the absorption of nutritive enemata has deservedly occupied the attention of the profession, and is invested with a new interest by the recent statements of a number of independent observers that something of a reversed peristaltic action takes place. It has been even claimed that the entire intestinal tract may be permeated by injections. The deduction would seem logical, the higher the enemata can be safely and conveniently carried the more surely will the absorptive and restorative processes be aided thereby.

In certain chronic diseases of the large intestine I have been equally confident of the benefit secured by this continuous use of hot water, and, although I have not as yet had occasion to use water thus applied in dysentery, either hot or cold, it would seem that a trial thereof might be thoughtfully recommended.

The longer tubes are of easy application for the evacuation of the stomach. Said a friend, "they are not introduced, they are swallowed;" at least almost equally easy do they enter the stomach, in marked contrast with the ordinary stiff tube of the stomach pump. A tube of this character and an ordinary rubber syringe are all that are necessary for the speedy and effective emptying of the stomach; and feeding by this means is, in like manner, easily accomplished. This I have had recourse to in a number of instances with children as well as adults.

The *modus operandi* is too simple to require detailed description. For the secondary effects the siphon is the simplest and most convenient method, from a height sufficient to insure a slow but continuous current.

¹ One of these tubes was used in washing out the deep sinns in the case of our late President.

Usually it is well to lengthen the tubes by connections of rubber tubing as deemed convenient.

Although I have written in an exceptional enthusiastic manner, I assure the profession I have kept within the limit of the seeming just deductions from my experience in these directions, lest it might appear that I was a partial and untrustworthy witness for truth. I am convinced that results will confirm more of good than I have indicated.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

M. M. RICHARDSON, M. D., SECRETARY.

JUNE 6th, 1881. DR. INCHEs read the regular paper on

A CASE OF ABSCESS OF THE LUNG.²

DR. BOWDITCH asked if there had been any examination as to the position of the heart. That was an important point in the diagnosis between pleurisy and pneumonia.

DR. INCHEs replied that there had been no percussion with that view. There had been, however, no disturbance of pulse or respiration.

DR. BOWDITCH asked whether the lower part of the back was resonant or flat.

DR. INCHEs replied that it was flat.

DR. BOWDITCH then asked if it was not singular that after the discharge of pus there was no evidence of it in the lung; it seemed to him strange. The facts did not convince him that there was not, after all, a considerable effusion into the chest. The fluid may have got through the pleura.

DR. INCHEs thought there would necessarily be air in the pleural cavity in case of perforation into the lung. There was no trace of it. As to the absence of gurgling and moist râles he would say that no examination could be made at the time without endangering the life of the patient. None could be made between the twelfth and the twenty-third days. When it was safe to examine gurgling and bubbling sounds were heard.

DR. MARTIN, of Roxbury, said that, thinking the regular paper was to be on a case of gangrene of the lung, he would briefly report two such cases which had occurred in his practice:—

The first case was that of an Irishman, forty-five years old, who had had slight cough for several weeks. With the cough was an increasing debility. At the first examination, the only symptom being slight cough, Dr. Martin found the right lung very flat with bronchial respiration and broncho pleurisy; no crepitation; no signs of pneumonia. He was told to go home and take nourishing food and quinia. In twenty-three days patient had great hæmorrhage from the lungs and fetor. He continued to have these hæmorrhages very profusely. Supporting treatment with ergot and digitalis were ineffectual. In order to correct the terrible fetor Dr. Martin took a gallon of impure carbolic acid and ten pounds of unslacked lime, and having put into several dishes from one to two pounds of lime he poured on these one pint to six ounces of carbolic acid. The acid slacked the lime and a very sharp vapor was thrown into the air which was very decidedly perceptible to the person

² See page 415 of this number of the JOURNAL.

breathing it. It corrected the fetor and the hemorrhage ceased in three hours, which had been going on for ten days. The whole aspect of the case was improved. The treatment was simply to inhale this vapor. There was no doubt that it had great effect on the diseased parts of the lungs, or at least that it arrested the progress of the disease and corrected the fetor. The patient recovered. This was twenty years ago. He has had no trouble with the chest since.

The second case occurred recently. A man of sixty had gangrene of the lungs in full blast. He had been under the care of a female practitioner who had given him much treatment without effect. The fetor in the room was so great that it was very difficult to remain in it. The patient's system was not much affected. Pulse good and temperature not much elevated. The upper part of the right lung was the seat of the trouble. Some flatness at upper third of right chest, where there was also gurgling sounds. Supporting treatment was given and salyelic acid by which the fetor was much ameliorated so that in three or four days it was with difficulty perceived. He took bark and nourishment and got better. The interesting point in the case was this: In the same house there was an idiot who had burned her thigh a year before. There was a granulating patch left about as large as the palm of the hand, which had not cicatrized. Dr. Martin saw this girl about two weeks after being called to the man with gangrene. A white substance of a glutinous nature had appeared on the surface of the sore. From the centre to the circumference this white deposit diminished in thickness. Nothing like the original surface was to be seen. There was neither trouble in the throat nor any constitutional disturbance. After that the tissues beyond became much inflamed and swollen. Sustaining treatment, quinia, stimulants, etc., had no effect, and she died. It was evidently a blood poison. Before death took place this white substance had decomposed. There was no sloughing, no formation of pus. The edges turned black and broke up, part drying and part softening. The patient with gangrene, after he was thought to be out of danger, with little cough, etc., suddenly died. There was no diphtheria in the region, and nothing bad about the drainage. The cause of the diphtheritic membrane seemed to be the air thrown out of the gangrenous lung. The effect of the carbolic acid (in the first case) was very remarkable.

VACCINIA.

With regard to the vaccinia of Cohasset Dr. Martin said that after having been disappointed some thirty times in investigating what were supposed to be epidemics of vaccinia some cases were reported to him by Dr. Cushing. Having been so often disappointed he declined to go to see them, but asked that some of the crusts should be collected and sent to him, that he might test them. The crusts were sent, and though he had no faith in them, there being in their appearance nothing indicative of vaccinia, he made six inoculations with them into a heifer. At the end of a week one vesicle had appeared. With this six points were charged. Next day one child was vaccinated without any hope of result. A week later went to see the child and was astonished to find two very fine vesicles peculiar to cow-pox. There was no doubt as to the authenticity of the case. Dr. Martin then wrote again to Dr. Cushing and got one half a crust more. Eight inoculations into the heifer were made with this crust from which two

vesicles were obtained. From these successful vaccinations were made. From the second remove fourteen vaccinations on children were made in one day and a vesicle resulted in each case. These vesicles were very beautiful in every way. There is a great difference between the various original stocks of cow-pox virus, which can only be detected by an expert. The peculiarity of this was that on the eighth day the point of inoculation still consisted of a number of small vesicles which had not become confluent. Dr. Martin then went to Cohasset and found the disease at about the sixth day in one cow and at the fifth in another. The whole history of these animals was exactly consistent with that occurring in the milk animals generally. All the cows milked by hand were affected. Those suckling did not have it though it would appear about ten days after the cow had stopped suckling its calf. It never appeared on the dry cow or on heifers that had never borne calves. The disease is never found on any part of the cow except the roots of the udders.

Dr. Martin later visited another large dairy in Cohasset, where he found eight to sixteen cows with traces of the vesicle, the crusts being still adherent. Others had cicatrices; twelve to fifteen had been affected. He found, also, a man with a vesicle at the fourth day, which had been inoculated through a hang-nail of the thumb. The local physician informed him that during the last five years he had had twelve cases of dairy men who had pustules on their hands.

There was no doubt that Dr. Cushing's cases were true cow-pox, and as such were very important and interesting.

Another interesting point with regard to these cases was that the history of the epidemic at Cohasset goes back several years. In 1872 Dr. Tarbell came to him and said that there was an epidemic in the dairies of Hingham. The cases occurred among half a dozen imported Jersey cows. From the history of the cases and position of the scars there was no doubt that these were cases of cow-pox. This takes the history back nine years.

There have been many cases of cow-pox reported in America, but in every instance the cases have been found to be something else. If any authentic cases of vaccinia have ever been reported they are very rare. He did not think any ever had been reported in the United States.

The case of *variola equina* was of very great interest. Such a disease is so rare that the majority of writers deny its existence. Jenner said that the disease in the milk cow was inoculated from the horse, or at least stated that the virus was transmitted to the udder of the cow from the hands of a milker who had been taking care of horses affected with variolous disease. He thought he had discovered the connection between the variola of the milk cow and the diseased horses, but was never able to produce it by inoculation. Many times he took virus from the heels of greasy horses and inoculated other animals, but was never able to get cow-pox in this way. Other writers reported that they had made similar experiments and failed. Jenner was ridiculed. Another observer, however, had happened to come across a man on whose hands were vesicles looking like the vesicles of cow-pox. From these vesicles he took the responsibility of inoculating children, and produced a vesicle that could not be distinguished from variola *pura*. The animal was discovered, and from it chil-

dren and heifers were inoculated, the disease thereby being produced. One of the plates of Jenner shows a child inoculated from the heel of a horse. These experiments, however, were lost sight of, and ridicule again brought against Jenner. At Paris horses were found with a fine eruption about the nose and nostrils, with pustules in the hair. From this children and young heifers were inoculated. A magnificent pustular eruption was produced in the child.

On the 9th of April Dr. Martin was called to see a hostler at the Highland Railroad stables. The man was found with a very red face, which was not the redness of erysipelas but rather that about a very vivid vaccination. After washing the discharge from the nose a pustule was seen to be just inside the opening of the nostril. On further examination a pustule was found on the thumb of one hand and the little finger of the other. The next day, after washing the hands with ether, two perfect vesicles were found. The areolæ had just begun to appear, and had extended one eighth of an inch. Some points were charged that day with clear pellucid fluid from the vesicles. Dr. Martin was so fully convinced of the character of the eruption that he vaccinated two children and a heifer, the inoculations being perfect in every case. The vesicle was perfect in form, and contained a small amount of fluid. Afterwards four more points were charged, and from these eight magnificent and perfect vesicles were produced. On the heifers the inoculations produced characteristic vesicles.

DR. CUSHING asked about the horse from which these vesicles probably came.

DR. MARTIN said the hostler had been washing scratchy horses. He had never had the same thing before. The man was terrified at the proposal that he should show the horse. Dr. Martin then went to Mr. Page, who had charge of the stables, and was told by him that the horses suffered from two different diseases. One was the scratches, and the other the grease. The latter is attended by much more inflammation, and has a very large and watery discharge. It occurs quite frequently, though much less so than the scratches. It consists of a sort of ulcerative centre, from which a watery fluid is exuded. There are also many minute vesicles. With regard to the use of animal virus Dr. Martin said that he began its use strongly prejudiced against it. He did not believe in it, and had no faith in its good results. He soon abandoned all other means of procuring virus, and now uses none except from the heifer.

Adjourned.

BOSTON SOCIETY FOR MEDICAL SCIENCES.

JAMES J. PUTNAM, M. D., SECRETARY.

NOVEMBER 23, 1880. DR. WARREN made a communication accompanied by specimens illustrating a mode of

PUSTULE FORMATION IN THE SKIN

differing from that hitherto described in the textbooks.

After recalling the usual forms of pustule, in which the rete is raised up by inflammatory products, the inflammation occurring in the skin itself, Dr. Warren referred to his own previous observations on the structure of carbuncle, in which he had shown that the pus, which is formed fairly beneath the skin, reaches the

surfaces largely through the little columns originally containing adipose tissue, thus producing the well-known eribriform appearance of the surface. Besides this avenue of escape for the pus, Dr. Warren had discovered that the papillæ also serve as channels through which still smaller masses of pus reach the surface of the skin.

When examined in an early stage of the process these papillæ are seen to be in an edematous condition, containing fluid and a few wandering cells, and distended into a polypoid shape, and sometimes to project a little above the surface of the skin.

The contents soon become thicker, the overlying portion of skin is invaded more and more, till at last it breaks down and the contents of the papilla escape. Under the microscope these are found to consist of cheesy, degenerated matter, like that of an old exudation. The carbuncular inflammation is thus really beneath the skin, the products filtering through the latter just as through a sieve.

In reply to Dr. White and to Dr. Fitz, Dr. Warren said that he was aware that this form of inflammation was not truly pustular, in a strict sense, since the pus was formed not in but beneath the skin. He had intended to use the word pustule only in a very general way, as surgeons are apt to employ it.

DR. WHITE thought this distinction between pustule formation and abscess, founded on the seat of the inflammation, should be kept strictly in view. In the former the papillary layer is only secondarily involved.

DR. WARREN said that he had not intended to approach the matter from the point of view of classification at all, but only to show that this form of inflammation, which is usually spoken of clinically as pustule formation, and in external appearance precisely resembling a pustule, takes place in the manner described. The question naturally arises, he said, whether other supposed pustules are not formed in this way.

DR. PUTNAM reported a case illustrative of the

LOCALIZATION OF CEREBRAL FUNCTIONS,

and showed a portion of the brain of the patient, who had been attacked four months before death with hemiplegia, from which the arm had almost entirely recovered while the leg had remained in *statu quo* to the last. At the autopsy the remains of an old hæmorrhage were found just beneath the cortex of the paracentral lobule near the gyrus fornicatus. The white substance in the neighborhood was softened. There was no other apparent lesion of the brain on either side except that described, which was on the side opposite to that of the paralyzed limbs.

DR. WHITNEY¹ made a communication, illustrated by microscopic specimens, on the

PLEURO-PNEUMONIA OF CATTLE.

It will be published elsewhere at length.

In reply to Dr. Fitz, Dr. Whitney said he could not say whether in the later stage of the disease the whole lining membrane of the bronchi is thrown off, but certainly this happens to the epithelial layer.

DR. FITZ said that he remembered having heard Virchow speak of this cattle disease as the type of acute interstitial pneumonia, and certainly its resemblance to human pneumonia, and especially the so-called dissect-

¹ Vide Third Report on Contagious Pleuro-Pneumonia. By Dr. Charles P. Lyman, published by the direction of the Department of Agriculture at Washington.

ing pneumonia, is very striking. The enormous size of the lymph space is very interesting. He thought this affection analogous to phlegmonous erysipelas, both being forms of lymphangitis.

In further reply to Dr. Fitz, as to whether the gelatinous material described might be an artificial product, Dr. WHITNEY said that he had seen it in specimens from fresh as well as from hardened lungs, but had not isolated it.

TUMOR OF THE ORBIT.

Dr. WILLIAMS showed a tumor removed from the orbit and believed to be sarcomatous in nature. He could not tell from what tissue it grew; certainly not from the eyeball. Dr. Jeffries, who had examined the patient, said that he did not look as if affected with cancer. The portion of the growth which could be felt was soft and suggested a cyst, which was believed, however, not to be the case. Considering its age and extent it was singular, if sarcomatous, that the eye had not been attacked.

Dr. FITZ said that the growth under the microscope showed more intercellular space in proportion to the cellular part than is common in sarcoma, and quoted Dr. Whitney as having found other parts looking myxomatous. It seemed to him not improbable that the tumor really grew from the fatty tissue at the back of the orbit.

Dr. WILLIAMS said that most of the tumor was more dense than this part, but that he had entertained the possibility of its being myxomatous.

Dr. WIGGLESWORTH related a case of

LOCAL COMMUNICATION OF FAVUS

from a cat to a poorly-nourished little girl who had been in the habit of holding the animal in contact with the part at present diseased, in order to illustrate the greater vulnerability of the skin at different ages and in different states of vitality. He referred to experiments of Dr. White and himself with regard to the inoculation of favus, showing how difficult this is in healthy subjects.

Dr. WHITE thought that so far as vegetable poisons are concerned the condition of the skin made no difference. With favus it may be otherwise, but certainly *tinia tonsurans* will run through a lot of healthy as well as of diseased patients. *Tinea versicolor* also he had seen in the healthiest of persons. He thought the reason it is believed to occur oftenest in consumptive cases was that such persons are so often stripped for examination of the chest. With regard to age as determining susceptibility, Dr. White thought it was different; it was only the effect of constitutional diseases to which he had been referring.

TUESDAY, JANUARY 18, 1881. Dr. BOWDITCH described some experiments, which will be published in *Foster's Journal of Physiology*, 1881, that had been made by Dr. Southard and himself, to determine more accurately than before¹

THE RELATIVE VALUE OF TOUCH AND SIGHT IN DETERMINING THE POSITION OF OBJECTS IN SPACE.

In addition to the methods previously described cards were used bearing concentric circles ruled round a black point which served as the object for localization. A sharp-pointed instrument was used instead of

a pencil, and the distance between the holes pricked in the card and the black point aimed at furnished a measure of the accuracy of localization.²

The experiment was also tried of allowing different lengths of time to elapse between the localization by sight or touch and the movement of the hand toward the object, the eyes being closed during the interval. In this way it was found that after about two seconds the accuracy of localization was greater than at first, but that after this it speedily declined.

Dr. WADSWORTH asked how long a time Dr. Southard worked at one sitting, and suggested that some of the results might, perhaps, be explained as being the effect of fatigue.

Dr. BOWDITCH said that Dr. Southard used every precaution in the way of control, experiments, etc., to eliminate the action of this influence. In answer to a further question of Dr. Wadsworth, Dr. Bowditch said that Dr. Southard had found that he worked the most accurately on days when he was feeling bright and well.

In reply to Dr. James, Dr. Bowditch said that arrangements had been made in some of the experiments so that the same distances at different parts of the chart should correspond to the same visual angles in the eye of the experimenter.

In reply to Dr. Wadsworth, Dr. Bowditch said that not enough experiments had been performed to determine whether, when the attempt at localization was made with the opposite hand to that which had placed the object, the error was greater or less according to whether the hand was forced to move towards or away from the median line of the body.

In reply to Dr. Cabot, Dr. Bowditch said that no doubt the results would be different with different observers, but also, in reply to Dr. Putnam, that each individual quickly reached a point beyond which he did not improve farther.

Dr. JAMES recalled the fact that Vierordt had worked out a curve of memory in an analogous set of experiments to these, and had made it out to be almost identical with that established by Dr. Bowditch.

ERUCTATIONS.

Dr. GARLAND made a communication on the subject of eructations,³ referring to a paper by Weissgerber, and giving the results of observations upon himself. The act consists in the noisy ejection of air previously swallowed. This swallowing of air may take place with great rapidity and to an enormous degree, especially with hysterical patients. Under these circumstances the air usually passes only into the œsophagus, but it may be carried into the stomach.

In reply to Dr. Bowditch, Dr. Garland said it was not definitely known how the sounds were produced, perhaps by the sudden opening of the upper end of the œsophagus.

Dr. Garland said it seemed to him as if the movement of drawing the air into the œsophagus coincided with elevation of the larynx.

Dr. JAMES, on the contrary, thought that in his case it coincided with falling of the larynx.

Mr. MINOT said he had been told that Greeks of the lower classes were in the habit of drawing tobacco smoke into the stomach instead of into the lungs, and retaining it there for fifteen minutes or so.

² Vide the previous experiments.

THE STERNUM AS AN INDEX OF AGE AND SEX.

DR. DWIGHT read a paper on the Sternum as an Index of Age and Sex,¹ in which he showed the statements made by Hyrtl and by Luschka, to the effect that the greater relative length of the body as compared with the manubrium is a distinctive mark of the male skeleton, to be so often wrong in individual cases that it is of no practical value.

Neither is the time at which the different parts coossify distinctive of the age of the subject, although it is often claimed to be so.

DR. PUTNAM showed a new modification of Pond's sphygmograph, allowing of the application of a measured pressure upon the artery.

A CASE OF CUT-THROAT, SHOWING THE ACTION OF THE FALSE VOCAL CORDS IN DEGLUTITION.

TUESDAY, FEBRUARY 15th. DR. A. T. CABOT reported a case of cut-throat, in which an opening was made into the glottis through which the action of the false vocal cords in deglutition could be well seen. The cut falling upon the thyroid cartilage, just beneath the notch and just above the insertion of the false cords, had passed horizontally backward, dividing the upper portion of the cartilage from the lower, so that an interval of nearly half an inch separated the two parts. This cut, though nearly horizontal, was a shade lower on the left side than on the right, and while the right false cord was intact the upper surface of the left had been shaved, and the sacculus laryngis slightly opened in its upmost part while the edge of the cord was uninjured. This had left a minute fistulous opening into the top of the ventricle of the larynx without impairing, however, the movements of the cord on that side. So far as could be told the arytenoid cartilages had escaped injury, and their movements were perfectly free. The parts of the thyroid thus separated were firmly fixed in their new position, and could neither be approximated to each other nor still further separated. A laryngoscopic examination through the mouth showed the epiglottis erect in its normal position in relation to the tongue and parts around, from which it would seem that the separation of the parts was due rather to the descent of the lower fragment than to the ascent of the upper.

At the time that the patient came under Dr. Cabot's observation, the wound had so far healed that only an opening large enough to admit the tip of the little finger was left immediately above the insertion of the false cords.

Except at one corner, the mucous membrane of the larynx was healed to the skin around this opening, thus leaving a window through which the action of the larynx in phonation and deglutition could be easily watched. In phonation the false cords were held widely apart, while the true cords approached each other and vibrated. It was in deglutition, however, that the mechanism was of especial interest.

When the patient swallowed, the first visible act was the closure of the false cords. These applied their edges tightly together, while the last glimpse of the true cords showed them widely separated. As the act of deglutition progressed the mucous membrane over the false cords wrinkled and was pressed forward as if the cords beneath had shortened. At this stage the

parts were drawn together and puckered as the neighborhood of the anus or other opening provided with a sphincter is during the action of that muscle. Finally, when the glottis rose, this folded mucous membrane was pressed firmly against and partly protruded through the external opening. Any saliva or liquid which was in the upper part of the glottis at the time was forcibly ejected from the opening during this final act. If bread was swallowed a small portion of it almost always found its way past the epiglottis down on to the false cords, and was thrown out through the opening. Its escape upwards into the mouth was apparently prevented by the epiglottis. In a normal condition of the parts, when the epiglottis is not separated by so great an interval from the false cords, and when a more convenient escape is not offered as in this case, it seems probable that the portions of food which fall below the epiglottis are pressed past and above it during this final rise of the glottis at the end of deglutition. If this were not the case, and if a particle of food remained upon the false cords, it would, when they relaxed, fall into the deeper parts of the larynx, and excite cough.

A consideration of the muscles² in the neighborhood makes it seem probable that the approximation of the false cords is produced by the action of the crossed fibres of the *posterior arytenoid muscle*, which, passing round the upper extremity of the arytenoid cartilages, extend upward to the epiglottis. Upon the contraction of these fibres the summits of the cartilages would be caused to bow towards each other, which would bring the false cords together, while the true cords might remain separated, as they were seen to do in this case.

The further sphincter-like action of the ostium laryngis would be caused by the contraction of the *musculus ary-membranosus*, an exceedingly delicate muscle lying beneath the mucous membrane of the *vestibulum laryngis*.

Recent Literature.

A Treatise on Diseases of the Nervous System. By JAMES ROSS, M. D. Illustrated with lithographs, photographs, and two hundred and eighty wood-cuts. Two volumes. New York: William Wood & Co. Pages xx., 594; xii., 1000.

This work is an exhaustive treatise upon the diseases of the nervous system; almost all writers of any note in the departments of anatomy, physiology, and pathology have been consulted and the results of their investigations are given. The illustrations are only in part original, by far the greater proportion being copied from writers of standard authority, as Charcot, Erb, Henle, Flechsig, Duret, Gowers, Duchenne, etc., and are well chosen to explain the subjects considered.

There is given first a general account of the structure and functions, then of the physiology of the nervous system as a whole; then follow the divisions in which are considered the diseases of the peripheral nerves, of the sympathetic, of the spinal cord, and of the encephalon. Each of these divisions contain introductory chapters in which are considered the anatomy, physiology, and pathology of these great divisions. These in-

¹ Published in the *Journal of Anatomy and Physiology*, vol. xv., 1881.

² The actions of these muscles are accurately described in Luschka's *Monograph upon the Larynx*, page 154.

introductory chapters are carefully written and are exhaustive; in them are grouped together certain facts and explanations with methods of examinations which are very convenient for reference and which cannot be found elsewhere in their entirety. The descriptions of special diseases are less full and satisfactory.

The chief criticism to be made upon the introductory chapters is that many elementary subjects are treated at too great length and with too great minuteness. The author has apparently tried to include everything, and has left little or nothing for the student to learn elsewhere, seemingly not considering that much of what he says will have been learned before reading his book. He has referred frequently to the views of others, giving abstracts thereof, in such a way that his style is in some places rather constrained and cramped.

The methods given for examining the motor apparatus and the sensory apparatus are good; the description and explanation of conjugate deviation of the eyes and rotation of the head and neck is very full and satisfactory. There is little to be added to the anatomical and physiological introductions to the diseases of the spinal cord and brain, which occupy respectively eighty and one hundred pages. These divisions are fully illustrated, the illustrations assisting materially to an understanding of the text.

In the division devoted to the peripheral nerves neuralgia of each nerve or set of nerves is considered separately; the same is true of spasm and contraction. It would be a saving of space and conduce to unity of description if the various forms of neuralgia had been considered together under one heading, the different varieties being mentioned simply as subdivisions.

The description of some of the diseases of the spinal cord are not quite what they ought to be. One would infer that infantile spinal paralysis begins with fever and convulsions more frequently than is really the case, the paralysis is said to be more "frequently general, involving the muscles of the four extremities, as well as a great part of the muscles of the trunk, especially those of the vertebral column, and sometimes those of the neck." Such general extension of the paralysis at the commencement is exceptional and cannot be said to be frequent.

Under Diagnosis, the difference between spinal paralysis and infantile cerebral hemiplegia is not clearly enough drawn; the latter being frequently mistaken for the former, a fuller description of the diagnostic differences would have been more satisfactory. Under treatment the description of the method of using the galvanic current might have been much improved.

The description of locomotor ataxia is complete in detail, but the grouping of the symptoms is rather too artificial and a student would not easily discover which are the earlier symptoms upon which a correct diagnosis can be formed in the initial stages of the disease. When speaking of the morbid anatomy the author says, on page 239: "The microscopical changes in the cord consist in the early stage of thickening of the interstitial tissue, increase in the number of nuclei along with the formation of enlarged and highly developed Dieter's cells;" while on page 241 he says: "All, however, are agreed that the process begins in the nerve elements themselves, and extends from them to the interstitial tissue." These two statements certainly do not agree together.

The symptoms ascribed to lesions of the cerebellum are more complex than some of the best authorities

consider them; the description includes phenomena due to pressure upon neighboring parts.

Some divisions of nervous disease are treated much less fully in proportion to their importance in practice than others; this is more especially true of chorea, delirium tremens, saturnine, and post febrile neurosis. Not only is the description of these defective, the treatment is also unsatisfactory.

"System-disease or a systematic lesion," is used to designate affections of certain regions. *Systemic* would seem to be a better adjective.

We have mentioned in detail some of the imperfections of this work, but the symptomatology of the different diseases is sufficiently accurate to guide the physician in his practice. The chief objection to the work will probably be found on account of its size and cost.

S. G. W.

Hand-Book of Vertebrate Dissection. Part I. How to Dissect a Chelonian. By H. NEWELL MARTIN, M. D., and WM. A. MOALE, M. D. New York: Macmillan & Co. 1881.

It is not improbable that the feelings of many of our readers on taking up directions for the dissection of turtles will be somewhat analogous to those of Mr. Dick in *David Copperfield* when told that his room was too small to swing a cat in. "You know, Trotwood, I don't want to swing a cat. I never do swing a cat. Therefore what does that signify to me!" If, however, any one should wish to dissect a turtle thoroughly, and to make the most of the material, we can recommend this book very highly. There are accurate directions for everything, and the student who will follow them conscientiously will, with the aid of some collateral reading, acquire more than a slight insight into vertebrate anatomy. Other works of a similar character on the dissection of the pigeon and the rat are already in progress. The series when completed will be very valuable.

T. D.

Fashion in Deformity. By WM. HENRY FLOWER. London: Macmillan & Co. 1881.

The above is the title of an excellent little book, intended for popular instruction rather than for the use of a student. The facts collected are well put, and the absurdity of the human mind in certain phases well illustrated.

In speaking of the deformities of modern society, the writer rather strains the comparison in making the mother who puts modern shoes on her child or who furnishes herself and her daughter with tight corsets the exact counterpart of the flat-headed Indian or the Chinese.

The savage or semitic follows blindly a barbarous custom, but the Caucasian has grown up unaccustomed to seeing the human kind without clothes, and the result is that every woman thinks her figure is, or ought to be, like the fashion plate, her corset "moulded to the figure," and her foot tapered to a point.

She does not wittingly distort, but aesthetically strives to attain to a faulty ideal.

Little tracts like this will, it is hoped, help to correct the public taste, and give us a more intelligent custom.

Medical and Surgical Journal.

THURSDAY, NOVEMBER 3, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.

HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE NATURE OF THE DIPHTHERITIC CONTAGIUM.

It is generally known that now for nearly two years Prof. H. C. Wood and Dr. Henry F. Formad, under the auspices of the National Board of Health, have been engaged in researches into the nature of the diphtheritic contagium. The result of their labor is now in the hands of the National Board, and will soon be published in full. In an address delivered October 11th, before the Academy of Natural Sciences in Philadelphia, Dr. Wood made a preliminary statement and communicated some of the facts and inductions which had been developed by their investigations, but requested that criticism be withheld until the full report is published. The following is a brief abstract of the lecture:—

In the spring of 1880 work was begun by inoculating rabbits with diphtheritic membrane, taken from actual cases, but with varying results. Where the membrane was merely introduced under the skin diphtheria was reproduced in only a few; some died of tuberculosis, secondary in character, in others no special effect was observed. When the poison was placed in contact with the mucous membrane of the rabbit's trachea, however, a false membrane was frequently abundantly produced, identical with the original in its microscopic and other appearances. It was further demonstrated that other irritants produced the same pseudo-membrane, in fact that "any tracheitis of sufficient intensity is accompanied by this product." Some micrococci were always found in the membrane thus formed, possibly less frequently than in true diphtheritic exudation. The production of false membrane, therefore, has nothing specific in it. These results have been already published, but the following have not.

As the result of a personal visit and investigation into an epidemic of diphtheria which occurred at Ludington, Michigan, Dr. Formad found a small town, part of which was built over a swamp which had been filled with saw-dust, and the soil of which was still so wet that few houses had cellars. It was in this district that diphtheria had prevailed; almost all the children had it, and about one third died. Autopsies revealed, besides the usual macroscopic appearances, a characteristic condition of the blood. "In every case the blood was found more or less full of micrococci, some free, others in zoöglæa masses, others in the white blood corpuscles." The viscera also contained

micrococci, especially the kidneys. These elements had not been found in some cases previously examined in Philadelphia, but during the last summer similar appearances were detected, showing differences in the disease, in degree not in kind.

Experiments upon rabbits determined that "the micrococci first attack the white corpuscles, in which they move with a vibratile motion. Under their influence the corpuscles alter their appearances, losing their granulations. They finally become full of the micrococci, which now are quiescent, and increase until the corpuscle bursts and the contents escape as an irregular, transparent mass full of micrococci, and form the so-called zoöglæa masses. In the diphtheritic membrane the micrococci exist frequently in balls, and it is plain that these collections are merely leucocytes full of the plant. The bone-marrow of the animal was found full of leucocytes and cells containing micrococci."

By another series of observations it was demonstrated that the rabbits had perished with diphtheria, and further that the micrococci "must be either the poison itself, or the carriers or producers of the poison."

From a series of culture-experiments it was determined that the virulence of the poison may be materially modified by artificial culture, that the malignancy of the case furnishing the poison proportionately affects its vitality under artificial culture, and that after drying and exposure to air for several weeks the viability is reduced, "the micrococci not only looked like those from ordinary angina, but acted like them. They were not dead, they had still the power of multiplication, but they no longer grew in the culture fluid beyond the third or fourth generation." It is concluded that, therefore, the power of rapid growth in culture-fluids and in the body of the rabbit is not a specific character of the diphtheria micrococcus; and, further, that there is no specific distinction between it and the micrococcus usually found on the tongue and digestive tract.

The lecturer's theory of diphtheria is as follows: "A child gets a catarrhal angina or tracheitis. Under the stimulation of the inflammation-products the inert micrococci in the mouth begin to grow, and if the conditions be favorable the sluggish plant may be finally transformed into an active organism, and a self-generated diphtheria results." It is plain that if this be correct there must be every grade of case between one which is fatal and one which is checked before it fairly passes the bounds of an ordinary sore throat. Every practitioner knows that such diversity does exist. Conditions outside of the body also may favor the development of inert into active and virulent micrococci, which are capable themselves of originating the disease when brought in contact with the upper air-passages, especially the tender throats of children. In this way sporadic and endemic or epidemic diphtheria may be explained.

The influence of this theory, if it shall be confirmed and accepted, will be felt particularly in two directions: in the first place more attention will be

paid to the favoring and predisposing conditions, with a view of prophylaxis; and, secondly, local antiseptic applications to the throat in diphtheria will assume relatively a highly important place in the treatment, and be placed upon a sound scientific and clinical basis. What these conditions are, and what the best agents to be used to kill the micrococci, are questions still under consideration.

CRIMINAL INSANITY AND LEGAL RESPONSIBILITY AS ILLUSTRATED BY GUILTEAU.

THERE seems to be now more disposition in various quarters to entertain the possibility of Guiteau's insanity than at first. The suggestion that he would prove insane was certainly not well received when the *JOURNAL*, notwithstanding the unpopularity of such a view, felt constrained to give expression to it shortly after the commission of the assault on the President. Some of those, however, who are compelled, upon a better acquaintance with the facts in his history when considered apart from the sentiments inspired by his crime, to admit a certain degree of mental obliquity, find that this is entirely compatible with responsibility and that the gallows would still therefore be not only a fitting and necessary, but also a *just* termination to his trial. This view of the subject being propounded in the abstract in an article by Dr. William A. Hammond in the November number of the *International Review* on the Punishability of the Insane, has proved very popular. It is there announced that the opinion of Dr. Isaac Ray and others that a lunatic should not be held responsible for a criminal act committed within three days before or after the occurrence of a fit is "too absurd to require an attempt at refutation," and the conclusion is reached that an individual may be medically insane, and yet not a lunatic in a legal sense. His brain is diseased, either temporarily or permanently; his mind is not in all respects normal in its action, — and yet he is responsible for his acts. Many of the insane are clearly irresponsible, and their punishment is demanded only by the imperative necessity which exists of securing the safety of society by preventing their committing criminal acts. This should be done in that way which experience shows is most conducive to the accomplishment of the end in view, even if it involves the taking of the life of the lunatic.

In closing this ingenious article the writer deprecates the morbid sentimentality relative to the rights of certain kinds of lunatics who are no better than wild beasts — having previously, in another part of his article, reflected that the protection of society might with propriety regard the hydrophobic dog and the lunatic in the same light — and concludes that the question in the case of the criminal should not be "Is he insane?" but, "Is he responsible?"

A writer in the *Nation* begins what he says in an article on Guiteau's Case very pertinently thus: Whether Guiteau is responsible for the assassination of the President or not, it is obviously of great interest to the community that the question should be thoroughly sifted — not only for the sake of the proper

administration of justice, but to determine the status in the community of the class to which Guiteau belongs.

A little farther on the article continues: —

The case is one in which "expert" testimony will be probably of the least possible value. The testimony of medical experts on the subject of insanity has fallen of late years into great disrepute in courts of justice, partly because it is highly paid, and can therefore generally be produced in any quantity on either side which has money at command, and partly from the fact, which no one who is at all familiar with medical inquiries into insanity can have failed to notice, — though, curiously enough, it has attracted little attention from the courts, — that the medical and the legal view of insanity are not only different but are radically opposed to each other. In any criminal case the only thing the law cares to find out is whether the accused is responsible for the act charged against him. If he is not, punishment would be unjust to him, and could have no deterrent effect upon others similarly situated. In order to determine the question of responsibility there are three common tests applied, which are very simple, and usually easy of application: first, did he know the nature and quality of his act; second, has he the capacity to distinguish right from wrong; and third, did he act under a delusion as to some matter of fact which, supposing it to be no delusion, would have justified the act?

Now these are not the tests necessarily applied by physicians at all. Their inquiries are directed to the investigation of the condition of a man's mind, not in reference to responsibility for a particular act, but with reference to his mental state as compared with what they regard as a healthy normal condition. Any departure from this is a symptom of mental disease. This difference would be of less consequence if it were in some way brought clearly into view in court. If medical experts were asked, for instance, to testify under oath whether on a given state of facts they were of opinion that the accused was responsible for the act he is charged with, they could answer intelligently. But, for the technical reason that to do so would be to let witnesses invade the province of the jury, this, under our system of law, is not permitted, and expert witnesses are generally asked whether, on a given state of facts, the man was "sane" or "insane." Now it admits of very simple demonstration that the answer to this question may be wholly irrelevant. It not infrequently happens that persons actually confined in asylums are brought into court to testify to matters within their knowledge. They are of course "insane," and yet at the same time they may be good witnesses, and would be responsible for perjury if they should commit it. In the same way a perfectly valid will may be made in an asylum, for the capacity of the testator, like the responsibility of the criminal, is dependent solely upon the amount of intelligence he possesses with regard to the particular transaction involved — in one case the disposition of his property, in the other the crime.

But in Guiteau's case there will probably be little necessity for medical expert testimony on either side, nor would the jury be likely to be affected by it one way or the other. If several members of his family have been, as is stated, insane, this fact, once proved, would do more to establish a doubt in the minds of an ordinary jury than all the testimony of all the experts in the country with regard to hereditary insanity. The question as to his responsibility must in all probability be determined by the application of the ordinary legal tests to which we have referred — by a consideration of the man's appearance, demeanor, conversation, past history, and his own explanation of his conduct.

In a communication to the *New York Medical Record* of October 29th, apparently suggested by an editorial in the same journal of October 22d, another writer, taking the medical view of insanity, and probably himself one of the experts referred to by the *Nation*, after summarizing very forcibly some of the striking points in Guiteau's history indicative of his insanity, says: —

The claim made in several journals that Guiteau is legally responsible, because "he knew what he was about," now shows a fear of death, took measures to secure himself against mob violence, etc., sounds rather like the prevailing cant among a certain class of lawyers than the deliberate opinion of scientists. No competent alienist ever attached weight to the apparently and at times actually methodical actions of lunatics except to consider those very lunatics more dangerous than their weaker-minded comrades, and therefore believed it incumbent to seques-

trate such lunatics, before all others, for the safety of society. There is not a scintilla of doubt in my mind that if Guiteau, with his hereditary history, his insane manner, his insane documents, and his insane actions, were to be committed to any asylum in the land, he would be unhesitatingly admitted as a proper subject for sequestration. The conclusion concerning his legal responsibility following from this is so self-evident that it will require no rebuttal of the "mad dog" argument urged in interviews and even in acknowledged works of merit, on my part, to distinctly set it forth. If the ridiculous dictum were to prevail that lunatics are to be held responsible for all acts whose nature they appear to understand, our experts might sink to the intellectual level of the jury that pronounced Gosling sane, because he seemed to be well posted on the trial, without any loss to the science of medical jurisprudence. Gosling, in some respects at least, would at that time have behaved less absurdly than Guiteau; within sixteen months thereafter he died of paralytic dementia in a private asylum near Philadelphia!

A thorough study will convince an impartial and competent jury of medical examiners, before whom such a case should be laid, that Guiteau is not only now insane, but that he was never anything else, that his crime was the offspring of insanity, and that in every act he will betray the characteristic features of querulous monomania. They will also conclude that, inasmuch as his insanity is not the result of his own vices, but based on a defective organization inherited from a diseased ancestry, anything like responsibility, complete or partial, is out of the question.

It will be a matter of regret if the Guiteau matter ever comes before a jury. The temper of the whole land, and justly so, was never before so much excited against an individual as against this assassin.

We have thought it worth while to reproduce the preceding extracts concerning Guiteau's insanity, and the abstract question of insanity and responsibility which it necessarily brings up so prominently, as the *JOURNAL* was both prompt and outspoken in expressing its belief in the probability of the man's insanity, and subsequently in entering a plea for a full and fair investigation of all the points bearing on his case.

It seems tolerably evident that no other sentence than hanging will prove satisfactory to the vast majority of the public, who believe that the infliction of the death penalty is the surest protection against the repetition of this kind of crime by this kind of man. If such a sentence should be the result of a trial it is very desirable that it should be reached on definite grounds, that there may be not only a criminal the less but a precedent for future guidance the more, that a step may be taken toward reconciling medical insanity and legal responsibility, and if it is clearly accepted that the best thing to be done with the insane murderer for the good of society is to destroy him, as we would the hydrophobic dog, that we may at least enjoy the simplicity of this conclusion, and, perhaps, by extending slightly the application of the principle, profit by it in a corresponding modification of the provision made for our insane asylums.

THE SANITARY ASSOCIATIONS OF LYNN AND OF NEWPORT.

THE second and third annual reports, respectively, of the Sanitary Association of Lynn and of the Sanitary Protection Association of Newport have recently appeared. Both Associations find that many of their pearls are not cast before the right species of householders, and that much of the good seed which they have sown has fallen on sterile ground. At the

same time the officers of these excellent organizations seem thoroughly in earnest, and find somewhat to encourage them in their efforts for the welfare of their fellowmen, and we do not doubt that at no distant day these efforts will be crowned with a fuller measure of success and appreciation.

The Association of Lynn has issued during the past year two sanitary tracts, a large number of copies of which were distributed throughout the city. One of these tracts, No. 3, was *On the Evils of our Present Privy System*; the other, No. 4, *On the Tubular Wells of Lynn as a Source of Water Supply*. The latter was the outcome of a special investigation as to the character of the tubular-well water, then furnishing a part of the public supply, made by Dr. William B. Hills, the chemical analyst of the Association. The amount of work accomplished in the sanitary inspection of buildings has been somewhat less than last year, and is certainly not large; this indicates a certain apathy on the part of the members to avail themselves of the advantages offered by the Association. It is proposed for the ensuing year to adopt two additional rules pertaining to the inspection of buildings; one making it compulsory, in a mild sort of way, upon the members to submit their premises to an examination, and the other requiring the inspectors to send in their reports in every instance within one week after the inspection is made. Those who are benevolently inclined are reminded that the Association for the trifling sum of one dollar has undertaken to provide for persons of moderate means a full and thorough report concerning the sanitary condition of their premises, with recommendations as to needed improvements.

The Newport Sanitary Association reports that though much has been accomplished the ends brought about are as yet far from commensurate with the continuous, tireless, up-hill dragging of those having at heart the desire for public as well as private interest in sanitary protection. The secretary states that there has been a marked change in the people of Newport during the past year in their desire for sanitary knowledge, and in their households the result of this knowledge is equally noticeable.

At the present time the Association numbers sixty-eight members. Thirty-five inspections have been made and fifteen samples of water analyzed.

The services of the Association have been called for and given in a new direction, namely, in suggestions in relation to the plumbing and sanitary arrangements, and a supervision of the work while being done, in dwellings during construction.

The great advantage of such a course to those who are ignorant of what is necessary to sanitary requirements, and who are therefore unfitted to pass judgment upon the plans of the contractor, is at once patent.

In its endeavor to bring about improvement of the health arrangement of the premises of the people in general, and thinking that perhaps many among the poorer classes, who, for the lack of interest in such matters, could not be easily reached, would be induced

by the hope of a reward to place their houses in the best condition possible and to keep them so, the Association distributed twenty-five hundred circulars, offering prizes to the extent of one hundred dollars for such action on the part of landlords and tenants. But even money was powerless to awaken sufficient interest in the people to cause them to compete for these prizes.

For the benefit of members, monthly examinations of the city water are being made, and although the water is not entirely what could be wished, yet it compares so favorably with the wells that its use is recommended in preference to the latter.

A committee has been appointed to investigate the source of the city's supply of water, with a view of recommending, if practicable, a plan for the improvement of the quality of this supply.

The ice supply of the city has been the subject of investigation by the Association for some months past. A portion of the supply of one of the ice companies is derived from a pond into which drains the overflow from the cess-pools of several premises.

The attention of the city government is again called to the foul conditions still existing in many parts of Newport and to the necessity for a thorough system of sewerage, and in conclusion the city council is assured that it only requires the cooperation on its part which the members of the Association have a right to demand to demonstrate the equal value of the work they are prosecuting to the general public and to private individuals.

These private sanitary associations have found an appreciative field of operations in Edinburgh and in other cities of Great Britain and the Continent; there is no reason why they should not prove of as much use here, and we hope the future reports of the two organizations named by us may be of a character to encourage the formation of similar bodies elsewhere.

MEDICAL NOTES.

— The third quarterly meeting of the Worcester North District Medical Society was held at the Fitchburg Hotel, Fitchburg, October 25, 1881. Interesting papers upon The Theories of Pyæmia, were read by Drs. C. H. Rice and E. P. Miller, of Fitchburg. The Society were much gratified by the presence of the president of the State society, Dr. H. W. Williams, of Boston, who took part in the general discussion of the papers.

NEW YORK.

— At the annual meeting of the Medical Society of the County of New York, held October 24th, the following officers were elected for the ensuing year: President, Dr. Frederick R. Sturgis; vice-president, Dr. W. Gull Wyllie; secretary, Dr. Wesley M. Carpenter; assistant secretary, Dr. P. Brynberg Porter; treasurer, Dr. O. B. Douglas. The report of the censors was largely devoted to a recital of the disposition of cases that had come up under the medical law of 1880 regarding individuals practicing illegally in the city.

The interest that the Society had shown, through its board of censors, in the attempt to suppress fraudulent practitioners was demonstrated that in nineteen cases such persons had been convicted; although the grand jury had unfortunately not been sufficiently alive to the importance of the matter to bring the offenders to justice in every instance. In his annual report, as chairman of the committee on hygiene, Dr. John C. Peters mentioned that, after a careful inspection, he had found almost all the streets remarkably clean for New York, and perhaps most other cities. The city was also remarkably free from bad street-smells, he said, and very few ash and garbage barrels were seen about. The sweepers were working actively and well, the carts and horses seemed good, and many loaded carts were seen at or going to the dumps. In other times the river streets had been so filthy that it seemed as if very little pure air could reach the centre of the city after blowing over them from the North and East rivers; but now the air was, comparatively, very good.

— At the last meeting of the Academy of Medicine a letter to the president, Dr. Barker, was read from the French surgeon, M. Declare, in which he presented to the Academy a copy of his book, published in 1865, on the use of carbolic acid in the treatment of wounds and septic diseases, and claimed priority over Lister. He had been present at the meeting of the Academy a fortnight before, when Dr. Sims read his paper on the recent progress of peritoneal surgery, but was not sufficiently familiar with English to make any statement of his claims at that time. The publication of his book in Paris, in 1865, a copy of which he sent to Professor Simpson the same year, he held, was the starting-point in the general adoption of the antiseptic treatment; while Lister's book did not appear till 1867, two years later, and six years after he had made a demonstration of his methods of treatment in Paris before two surgeons, one of whom sent the details of the case experimented upon to Lister in Edinburgh.

— In consequence of the unprecedented drought that has prevailed during the past three months and the deficiency of storage capacity, the city has come to be in a perilous situation in regard to its water supply, and Mayor Grace has issued an appeal to the citizens, in which he exhorts them to stop the indulgence of a lavish or wasteful use of water, and to bear with patience the restrictions which must necessarily be imposed in regard to it. In order to husband the supply as far as possible, the Commissioner of Public Works, Mr. Thompson, has given orders to close the public drinking hydrants for man and beast, to stop the use of hose for washing sidewalks, stoops, areas, and house-fronts, to discontinue the sprinkling of streets, boulevards, roads, and park-drives, to furnish no more water to shipping, except in cases of extreme necessity when the water cannot be obtained elsewhere, to shut down still further the outer gates of the main distributing reservoir, and to reduce the pressure from the high service works. Mr. Thompson has also requested the police commissioners to issue imme-

diate orders to the members of the police force to visit every house on their respective posts and notify the owners and occupants of the imperative necessity and duty of stopping at once all leaks and waste of water, and that in every case where this notice is disregarded the water supply will be promptly cut off. There is at present, however, no fear of a deficiency of water in case of a great conflagration, since the full pressure at the Central Park reservoir could be put on at a moment's notice. It has always been the aim of the department of public works to keep this reservoir full for use in case of fire, and this course has not been deviated from in this emergency. The fire department is in telegraphic communication with the reservoir, and men are stationed there who would raise the gates immediately on receipt of an order to do so. The fire commissioners have also arranged with the owners of three tug-boats, which are fully equipped with powerful steam-pumps and hose, for their services in case of a fire in which salt water can be used. Brooklyn, as well as New York, is suffering from a scarcity of water, and the same precautionary measures to prevent waste are being adopted there.

Under the above circumstances it is rather an inappropriate time to put up a new public drinking-fountain; but on the 25th of October a very beautiful one in bronze, located at Union Square, was formally presented to the city by Mr. D. Willis James, who has taken a leading part in the providing of better homes for the working classes and other benevolent enterprises. It was principally owing to his exertions that the immense block of improved dwellings for the poor, between Seventy-First and Seventy-Second Streets, on the east side of the city, was erected.

— The following statement of fees collected for account of the health officer of the port from January 1, 1870, to September 30, 1881, was prepared by the collector of customs for the legislative committee investigating the health and quarantine departments:—

1870.....	\$29,058.00
1871.....	35,275.50
1872.....	35,581.00
1873.....	40,183.00
1874.....	40,306.50
1875.....	34,580.00
1876.....	36,763.00
1877.....	40,040.00
1878.....	46,813.00
1879.....	51,441.00
1880 (first three months).....	10,367.50
1880 (last nine months).....	39,520.00
1881 (first nine months).....	35,197.50

Total (eleven years nine months).... \$475,136.00

— One of the sergeants of the Central Park police having been attacked with a virulent type of small-pox, the entire force have been vaccinated and the police quarters in the park disinfected and fumigated by order of the Board of Health. The disease seems to be becoming epidemic in Jersey City; as many as twelve new cases being sometimes reported in a single day. The health officials complain that owing to the lack of facilities and of preventive legislation they are unable to isolate the cases. There is only one small-pox ambulance in the county, and patients, at all events, cannot be taken to the hospital without their own con-

sent; so that the chief resource of the health authorities is to quarantine the patients as well as possible at their homes. In the tenement-houses, of course, this is often impossible.

— Mrs. J. N. Schoonmaker, of Pittsburgh, has bequeathed \$10,000 to the New York Society for the Relief of Ruptured and Crippled.

PHARMACEUTICAL NOTE.

EPSOM SALTS. ADMINISTRATION.

A considerable proportion of Epsom salts can be added to an effervescent draught of Rochelle salts without its disagreeable bitterness being perceptible. Preparations of this character have lately come largely into use. — *Am. Jour. Pharm.*, September, 1881.

ZOEDONE.

The English chemists have lately been giving a good deal of attention to the making of "temperance" beverages, among which *zoedone* is one of the most popular. This is an effervescent phosphorated ferruginous water, which was invented and patented some three years ago by David Johnson, F. C. S. It is described as a most pleasant and refreshing drink, in which the peculiar iron taste is said to be very successfully masked by a peculiar flavoring syrup, which alone is kept a secret. The quantities of the active ingredients in each small champagne-bottle are given by the patentee as follows:—

Calcii phosphas	grs. 2 1-2
Ferri phosphas	gr. 1
Potassii phosphas	gr. 1-5
Sodii phosphas	gr. 1-12

Miscellany.

A PLEA FOR UNITED STATES MEDICAL EXAMINATIONS.

MR. EDITOR: The plan of having a United States Medical College at Washington has been strongly advocated before now, and while this is most desirable, it seems hardly possible of realization, for many reasons, in the present state of congressional action, which almost amounts to "not one cent for science but millions for mud-creeks" (to alter the old-time motto slightly). On the other hand it appears to the writer an immense advantage at a slight cost could be obtained by a plan similar to the following:—

Medical boards of examiners, consisting each of ten Army and Marine Hospital Surgeons, to meet twice a year at the capital of each State, allowing two weeks for each session.

Certificates to be required from some regularly incorporated college or school of medicine that the candidate had passed four continuous years in medical study, including not less than six months' service as house officer or assistant in some general hospital having at least one hundred beds; that the candidate was twenty-one years of age, and that the degree of doctor of medicine had been conferred. An acquaintance with English, Latin, and German. The examinations to be written and oral: the written to test the theoretical, and the oral the practical knowledge in each branch. The oral to consist almost entirely in

identifying anatomical dissections as specimens, proving physiological facts; surface-marking and operative surgery on the cadaver, with medical, surgical, and pathological diagnoses upon patients and specimens, including operative obstetrics on cadaver or phantom. *Materia medica* and the actual mode of administering drugs *not* to be made a part of such examination, certificates from the professors in those branches being *accepted* and required. This would leave no basis for outcry of special schools against old-school persecution. But the physiological action of alkaloids, and doses of poison with antidotes, could well take their place.

The written examinations to be the same for all coming up at the same time; the oral chiefly from specimens, dissections, and cases determined by lot.

The idea being to make the whole examination prove that the candidate must have dissected, seen, handled, and recognized similar specimens or parts to those presented, and investigated clinical cases intelligently.

The certificates and examination being satisfactory, a diploma should be given, certifying that the candidate has passed the United States Medical Examinations, and is entitled to place U. S. in parentheses after his title of M. D. upon his sign, card, or door-plate.

A fee of fifty dollars to be charged for each examination, half of which would be refunded in event of failure to pass.

A severe penalty to be inflicted upon such as unlawfully used the above distinction of (U. S.) after their proper medical title.

The examinations in anatomy, physiology, chemistry, and poisons might be passed after two years of medical study, and the remainder after the four years were completed.

Enough temporary surgeons could be approved for substitute duty at the military posts, so that the service would not suffer by the absence of the regular army surgeons.

This outline is somewhat similar to the German "Staats Examen," and that of the Royal College of Physicians and Surgeons of England, being in America *permissive* instead of *compulsory*. The plan could be modified in detail without doubt to make it more efficient.

An appropriation of fifty thousand dollars by Congress annually would confer this great benefit upon the States and undoubtedly cover all expenses. After a few years the individual States would doubtless make such examination a condition for license to practice medicine within their limits.

The advantages of such a system would be: The total separation of the educating and examining boards, and a severe and impartial investigation of the students' practical knowledge by men not connected with any of the medical schools, and who have nothing to gain or lose by the success or failure of candidates. The fact should be recognized by the State, that the public at large is absolutely unable to judge of the real ability of a physician. The "personal equation" counts for everything, capability by itself for very little.

The great army of martyrs to ignorance, who silently go to their graves through acts of commission or omission on the part of their medical attendants, would steadily decrease, and some of our prolific medical schools would be obliged to raise their standards even at the loss of numbers and receipts. There is no doubt that

there would always be capable men enough to satisfy the demand. The experience of every other civilized country in the world proves this, as well as the fact that it is good economy to allow none but well disciplined men to practice medicine and surgery. Yours truly,

W. B. PLATT, M. D. (Harv.), M. R. C. S. (Eng.)
BALTIMORE, October 18, 1881.

ANNUAL MEETING OF THE AMERICAN ACADEMY OF DENTAL SCIENCE.

THE fourteenth annual meeting of the American Academy of Dental Science was recently held in Boston. The president, Dr. T. L. Williams, on calling the meeting to order said:—

This society has only arrived at its fourteenth birthday, but it is old enough to profit by experience. It has seen simple manual skill grow to become less rare than it was two decades ago; though its æsthetic application is yet far too uncommon. And there is reason for congratulation on the present awakening of the conviction, held by the founders of dental surgery, that sound opinions and safe practice may be expected only from a thorough knowledge of the principles and sympathies that in health and disease govern the human system, of which the mouth is a most important part. And, I may add, without this knowledge, the finest manual skill may be useless, or, indeed, mischievous. For the axiom in engineering is equally true in the practice, that the greater the skill misapplied, the more aggravated the blunder. But by a general zeal for knowledge of the fundamental principles of practice, we may hope for a higher advance than ever. And it is mainly by such knowledge that this Academy can deserve its name as a scientific body.

After the reading of the minutes of the previous meeting the reports of the secretary and treasurer were presented, the former showing that there are now on the roll the names of thirty-two members, six having been admitted during the past year, two having resigned and one died during that time. Appropriate resolutions on the death of Dr. Daniel Harwood, one of the oldest members, were adopted.

The following-named officers were elected: President, Dr. T. H. Chandler; vice-president, Dr. George T. Moffatt; recording secretary, Dr. H. F. Hamilton; corresponding secretary, Dr. E. B. Hitchcock; treasurer, Dr. L. D. Shepard; librarian, Dr. H. C. Merriam; censors, C. P. Wilson, J. H. Batchelder, and J. T. Codman.

PREVENTION OF PYLEMIA.

By no ventilation in the world can septicæmia, pyæmia, and erysipelas be blown out of the hospitals; not even by the most assiduous care in ordinary life can they be avoided, but only by the conscientiousness and prudence of the surgeon. If ever the excellent Simpson was right in his assertion that far more operated patients die in hospitals than in private practice, modern surgery may rather declare the contrary. If there is any danger of a mistake in the treatment of a wound it is more apt to happen in a private house, where it is more difficult to satisfy the accurate demands of modern surgery than in hospitals. — *Volkmann, Int. Med. Congress.*

REGULATING THE PRACTICE OF MEDICINE:
THE NEW YORK LAW.

SUCH as are interested in laws for regulating the practice of medicine in different States will receive with becoming discouragement the announcement that "the law of 1880" of this State is practically a failure. The Board of Censors of the Medical Society of the County of New York have made their first annual report concerning the working of the law and the results of prosecution for its infringement, and base their unwelcome verdict regarding its utility upon the stubborn facts of a sufficiently extensive experience before the grand jury and in the police courts.

It appears to be conceded by the gentlemen of the committee, as well as by the distinguished counsel for the Society, Mr. E. C. Ripley, of this city, that the law

is deficient in many important particulars. For instance, it has been proven that any person can register without a diploma and yet escape conviction on the charge of perjury. The District Attorney has expressed the opinion that such false swearing is not perjury in the strict sense of the term, and cannot be punished as such according to the provisions of the law of 1880. Such an opinion, if sustained, breaks the backbone of the law, and makes the latter virtually a dead letter. In view of this being possible, it would appear to be unwise, in any future amendment of the law, to allow any latitude whatever to an individual registering, and to hold him to the strictest accountability for the slightest misconception of his privileges. How this can best be done must be a subject of careful study. — *New York Medical Record.*

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 22, 1881.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2869 (no report from New Orleans): 1202 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 899, consumption 382, diphtheria and croup 277, diarrhoeal diseases 259, lung diseases 169, typhoid fever 117, malarial fevers 69, small-pox 64, scarlet fever 60, cerebro-spinal meningitis 19, whooping-cough 15, puerperal fever nine, measles six, erysipelas two, typhus fever two. From *malarial fevers*, District of Columbia 17, New York 12, St. Louis 11, Brooklyn 10, Philadelphia seven, Baltimore four, Buffalo and Charleston two, Boston, Cincinnati, Providence, and Nashville one. From *small-pox*, Chicago 41, Pittsburgh 11, Philadelphia nine, Cincinnati two, New York one. From *scarlet fever*, New York 28, Pittsburgh nine, Brooklyn six, Philadelphia five,

Baltimore three, Chicago and St. Louis two, District of Columbia, Buffalo, New Bedford, Webster, and Westborough one. From *cerebro-spinal meningitis*, New York six, Philadelphia, Chicago, Boston, St. Louis, Baltimore, District of Columbia, Buffalo, Nashville, Cambridge, Fall River, Lawrence, New Bedford, and Holyoke one. From *whooping-cough*, New York and Baltimore three, Philadelphia, Brooklyn, and Boston two, Providence, Somerville, and Newburyport one. From *puerperal fever*, New York, Chicago, Boston, St. Louis, Cincinnati, District of Columbia, Pittsburgh, Buffalo, and Holyoke one. From *measles*, Cincinnati two, New York, Chicago, Boston, and Buffalo one. From *erysipelas*, New York and Brooklyn one. From *typhus fever*, Chicago two.

Three cases of small-pox were reported in Brooklyn, five in

Boston, one in St. Louis, eight in Cincinnati, and 57 in Pittsburgh; diphtheria 44, typhoid fever 44, scarlet fever four in Boston; diphtheria nine, scarlet fever three in Milwaukee.

In 42 cities and towns of Massachusetts, with a population of 1,099,520 (population of the State 1,783,086), the total death-rate for the week was 21.29 against 23.50 and 21.01 for the previous two weeks.

For the week ending October 1st in 149 German cities and towns, with estimated populations of 7,824,824, the death-rate was 21.8. Deaths reported 3281; under five 1605; pulmonary consumption 432, acute diseases of the respiratory organs 213, diphtheria and croup 181, diarrhoeal diseases 162, scarlet fever 126, typhoid fever 63, whooping cough 38, measles and röteln 18, puerperal fever 14, small-pox (Dresden, Aachen, Essen) three, typhus fever (Thorn) one. The death-rates ranged from 14.1 in Dortmund to 40.6 in Kiel; Königsberg 33.6; Breslau 26.2; Munich 27.1; Dresden 25.5; Berlin 23.4; Leipzig 16.8; Hamburg 18.2; Hanover 22; Bremen 16; Cologne 21.9; Frankfurt 19.4; Strasburg 22.7.

For the week ending October 8th in the 20 English cities with estimated populations of 7,608,775, the death-rate was 18.8. Deaths reported 2739: acute diseases of the respiratory organs (London) 227, scarlet fever 136, diarrhoea 108, fever 68, whooping-cough 49, measles 47, diphtheria 28, small-pox (London 13) 15. The death-rates ranged from 12.4 in Bristol to 24.7 in Newcastle-on-Tyne; Birmingham 17.3; Sheffield 18.3; London 18.6; Leeds 18.8; Manchester 21.9; Liverpool 22.7; Edinburgh 17.1; Glasgow 22.4; Dublin 18.7.

For the week ending October 8th in the 21 chief towns of Switzerland, population 479,934, there were 19 deaths from diarrhoeal diseases; acute diseases of respiratory organs 12, diphtheria and croup six, typhoid fever four, scarlet fever three, whooping-cough one. The death-rates were, Geneva 23.3; Zurich 21; Basle 18.4; Berne 16.4.

The meteorological record for the week ending October 22d, in Boston, was as follows:—

Date.	Barom-eter.	Thermom-eter.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM OCTOBER 22, 1881, TO OCTOBER 28, 1881.

BYRNE, C. C., major and surgeon. Paragraph 2, F. O. 26, C. S., from these headquarters, relieving him from duty in this department and directing him to proceed to his proper station, Benicia Barracks, Cal., is confirmed. S. O. 119, Department of Arizona, October 17, 1881.

HARRIS, A., major and surgeon. Granted leave of absence for one month, with permission to apply for an extension of nine months, and authority to visit Europe. S. O. 214, Department of the Missouri, October 20, 1881.

GARDNER, W. H., captain and assistant surgeon. The leave of absence on surgeon's certificate of disability granted him in S. O. 138, June 18, 1881, from A. G. O., extended three months on surgeon's certificate of disability. S. O. 239, A. G. O., October 31, 1881.

TRIMANE, W. S., captain and assistant surgeon. The extension of his leave of absence on surgeon's certificate of disability granted him in S. O. 112, May 16, 1881, from A. G. O., still further extended three months on surgeon's certificate of disability. S. O. 238, A. G. O., October 20, 1881.

BROWN, P. R., captain and assistant surgeon. Relieved from duty in Department of the East, and to report in person to the commanding general, Department of Texas, for assignment to duty. S. O. 240, C. S., A. G. O.

COMPTON, W. H., captain and assistant surgeon. Relieved from duty in the Department of the Platte, to proceed to New York city, and, on arrival, report by letter to the Surgeon-General. S. O. 240, C. S., A. G. O.

PAULSON, H. O., captain and assistant surgeon. Relieved from duty in the Department of the East, and to report in person to the commanding general, Department of the Platte, for assignment to duty. S. O. 240, A. G. O., October 21, 1881.

GARDNER, I. F., captain and assistant surgeon. Granted leave of absence for four months, with permission to apply for an extension of two months. S. O. 238, C. S., A. G. O.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, JULY 1, 1881, TO SEPTEMBER 30, 1881.

BAILLY, P. H., surgeon. Detailed as member of board to examine keepers and crews of life-saving stations. September 8, 1881.

To inspect the service at stations in Maine, New Hampshire, and Massachusetts. September 9, 1881.

WYMAN, WALTER, surgeon. When relieved of special duty as medical officer, revenue bark Chase, to rejoin his station, via Washington, D. C., August 18, 1881.

LONG, W. H., surgeon. Detailed as chairman board of examiners. September 12, 1881.

Granted leave of absence for twenty-four days. September 24, 1881.

PURVANCE, GEORGE, surgeon. Detailed as member board of examiners. September 12, 1881.

SAWYER, H. W., surgeon. Detailed as recorder board of examiners. September 12, 1881.

GODFREY, JOHN, passed assistant surgeon. To proceed to Pascagoula, Miss., as inspector. July 27, 1881.

GOLDSBOROUGH, C. R., passed assistant surgeon. To proceed to Havre de Grace, Md., as inspector. July 27, 1881.

Granted leave of absence for thirty days. September 1, 1881.

COOKE, H. P., assistant surgeon. Granted leave of absence for thirty days. August 12, 1881.

CARTER, H. R., assistant surgeon. Granted leave of absence for eight days. September 24, 1881.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—A regular meeting of the Society will be held on Monday evening, November 7th, at eight o'clock, in the hall of the Medical Library Association, 19 Boylston Place. Reader, Dr. H. Joy Jeffries. Subject, The Imitation of Syphilis. Semi-annual election of members.

M. H. RICHARDSON, M. D., Secretary.

Lectures.

CLINICAL LECTURE.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK, OCTOBER 5, 1881.

BY PROF. A. JACOBI.

TANIA; EARLY OSSIFICATION OF THE CRANIUM.—
DIPHTHERITIC PARALYSIS AND ACUTE NEPHRITIS.

THE first case which I present to you to-day is that of Michael S., three years old. His mother says that when about a year and a half old he commenced to walk by taking hold of chairs and thus supporting himself, but that since then he has made no improvement, and that although three years old he is yet unable to walk alone. He also is unable to talk, although he utters a few words occasionally. The mother says, in reply to questioning, that the child is a hearty eater, but not voracious. She attributes his appetite to the fact that he has a tape worm. A few words in regard to that before I go on to speak of his retarded development, which is the reason why he is brought to us. Tape worms are introduced into the intestinal canal through the agency of raw meat. Rare meat will never convey them, and when raw meat is used as a remedy in diarrhoeas, as it frequently is, there is always this danger to be apprehended that you may have a *tania mediocanellata* developed as a result. Now, *tania* are of graver consequence in children than in the adult, because the *tania* which is found in children is not the *tania solium* which is usually communicated through the medium of raw ham, but the *tania mediocanellata* which is conveyed in the raw beef which the children are fed upon, and this variety of *tania* is far more difficult of expulsion than the *tania solium*. But, as I have said, there is something far more serious than this for which the child is brought here. He does not develop intellectually. He walks no better now than when he was only fifteen months old. Now, when a child of this age does not walk it is either because the extremities are paralyzed, or because the conductors of nervous force have lost the power of conveying the nervous stimulus, or because the brain is at fault. The mother says that the first teeth appeared at the age of five months. That is abnormally early. The first teeth usually appear at the age of seven months, being the lower central incisors. Then it is stated that the fontanelle was closed when the child was one year old. The normal period at which the anterior fontanelle should close is during the fourteenth, fifteenth, or sixteenth month. There is, as a rule, a direct connection between the appearance of the teeth and the closure of the fontanelle. When the teeth appear late the fontanelle closes late, and, on the contrary, when the teeth appear early the fontanelle closes early. There was in this child, then, a premature development of the teeth; at least they appeared two months before the usual time, and, contrary to what is usual, the first teeth to make their appearance were the upper central incisors instead of the lower. We find also that the fontanelle, in accordance with what I have stated, closed during the twelfth month, or at least two months earlier than in other children. In the large majority of cases in which a premature ossification of the fontanelle and cranial valves took place, the first premature incisors which made their appearance were those in the upper jaw. This appears

to occur so regularly that I am in the habit of looking at that anomaly as almost pathognomonic of cranial premature ossification. When there is premature ossification of the cranium, as the cranium and brain develop equally, the brain is prevented by its rigid case from developing properly, and when the ossification takes place equally the brain is dwarfed in its totality, and so the child remains behind both physically and mentally. Sometimes, however, it is the coronal suture which becomes ossified too early, and then development being hindered anteriorly the cranium and brain contents bulge out posteriorly, or if it is the parietal sutures which are at fault then the development takes place antero-posteriorly, and you have a bulging of the frontal and occipital regions and a flattened cranium. In such a case as this the prognosis must be very unfavorable because a condition of things exists, the cause of the tardy development, which we cannot alter, and there is hardly any indication for remedies. The mother says that all the temporary teeth made their appearance at eighteen months, and here again is an evidence of abnormally early ossification. The temporary teeth are not usually completed before the twenty-sixth month. Contrary to what you would suppose, convulsions rarely appear in this condition of things, and in this case there is no history of convulsions. The changes in the cranium and the consequent compression of the brain take place so slowly that the nervous tissue escapes irritation sufficient to produce such disturbances. Epilepsy, however, does occur; where the brain is compressed very early, as before or shortly after birth, idiocy is the result, but when the change takes place later epilepsy follows. Such cases of epilepsy go hand in hand with asymmetry of the cranium, the ossification taking place in one or other of the sutures, as I have before explained, while the cranium developed in such a direction as the unossified sutures permitted. It is not uncommon for epilepsy to arise during the eighth or tenth year of life, but when it can be traced back to early childhood it is probably due to early ossification of the cranium. Of course we must tell the mother that as far as the intellectual trouble is concerned the case is hopeless. A condition exists which we are unable to alter. For the intestinal trouble, the *tania*, I should use either kousso or kameela. The child might take one drachm of the powder of kameela in the course of two hours. He ought to be fed on oat meal and milk previously, and purged three or four times a day; then after the administration of the kameela he should be given a little milk, and if the *tania* does not appear in the course of an hour he should be given a dose of castor oil.

Our next case is that of J. K., aged four years. He was perfectly well until six months ago, when he had scarlet fever followed by acute nephritis; after that he had whooping-cough, and about four weeks ago he had an attack of diphtheria from which he was two weeks in recovering. About a week ago his parents noticed that he staggered when he walked, and that his voice had a nasal intonation. His urine now contains about forty per cent. in volume of albumen, so that the nephritic trouble still exists, and will certainly prove a formidable complication to deal with. It does not appear, on inquiry, that fluids which he drinks return by the nasal passages, and his father says that he noticed the peculiarity of gait before the nasal intonation of voice. It is not probable, however, that the locomotor disturbance preceded the paralysis of the palate to

which the nasal twang is due; it, from its nature, merely, was the first symptom to attract attention. This is a typical case of that form of paralysis which follows diphtheria; it is not, however, an invariable sequel of that disease, for it may happen that you will not see it in one per cent. of your cases, then you may have two or three such cases in succession; when it does occur it usually shows itself first in the soft palate, but never during the course of the disease. The soft palate may be incapable of performing its functions during the disease, and regurgitation of fluids take place, but then the paralysis is not nervous in origin, but merely mechanical. It is due to the thickened and oedematous condition of the mucous membrane and muscular tissue of the palate, just as in peritonitis you have constipation as the result of a similar condition in the muscular coat of the intestine. As the local inflammation and swelling subside, this paralysis disappears, to give place, however, after an interval, to the true paralysis of the palate, of which the case before you is an example. Here it is not, however, complete, because then there would be regurgitation of fluids through the nose, which there is not. There is only sufficient loss of power over the muscle to give a nasal twang to the voice. It has been stated by some observer that diphtheritic paralysis originates under all circumstances in the arches of the soft palate. This is incorrect. A number of cases have been reported in which other parts of the body were the first to become affected. I have seen cases where the arches of the palate escaped entirely, and there are instances on record where the patient has suffered from a paralysis of the accommodation muscles of the eye without a similar affection of the soft palate. Next in order of frequency the muscles of the eye become affected, resulting in strabismus when the paralysis attacks the recti, in paralysis of accommodation when the ciliary nerves become affected. When the ciliary nerves are paralyzed the paralysis is apt to be symmetrical; paralyzes of the rectus externus and internus are more frequently alternate. Next in frequency come the paralyzes of the lower and upper limbs; as a rule they involve a series of muscles at a time, and do not affect all the groups at once, improving in the same order as they became affected. After the paralysis has lasted some time the circulation begins to suffer, the extremities becoming bluish and cold; sometimes the muscles of the neck are affected so that the head cannot be held erect. In bad cases the abdominal and respiratory muscles share in the paralysis. When the paralysis attacks the muscles of respiration it is very dangerous, as it almost always sets in suddenly, and may result in apnoea and death. Paralysis of the pharyngeal muscles may be dangerous also in so far as it may permit the food to enter the larynx, thus giving rise to immediate suffocation or to a secondary pneumonia. With very rare exceptions the sphincters escape the paralysis. Sensory paralyzes occur subsequent to diphtheria, as well as motor, and when the two forms are associated they give the appearance of locomotor ataxia. I myself have observed a case of pure anaesthesia of the upper portion of the trunk. Where autopsies have been made of cases which have died during the course of diphtheritic paralysis thickening of the spinal nerves at the junction of the anterior and posterior roots has been found, also haemorrhages, also diphtheritic exudation in the superficial connective tissue in these places. Haemorrhages in the

spinal meninges with nuclear proliferation in the gray substance of the cord has been observed. Degeneration of the palatine nerves with fatty disintegration of the palatine muscles have also been discovered. It is certain that diphtheritic paralysis does not depend in every case on one and the same cause, but in most cases it appears to consist of a trophic affection of the motor system, almost always peripheral in origin, seldom central, if ever. One of the most characteristic features of this form of paralysis, which I ought not to omit mentioning, is that it follows no certain course, but passes by certain parts of the body to attack others. It is capricious in its order of development.

The usual duration of the paralysis of diphtheria is from eight to ten weeks, and the large majority of the cases get well. The treatment should be tonic and stimulant; let the patients be fed on beef, milk, and eggs, alcohol also in small quantities. Among the tonics iron is the principal one which you will use, choosing that form which is best suited to the case, as, if there is diarrhoea, you would naturally choose the sulphate of iron in preference to other forms. Among the nervines strychnia is the most efficient and powerful in its effects. A child of this age (four years) should take as much as one thirtieth of a grain in the course of the day; let him begin on one eightieth (three times a day) for a dose. When the respiratory organs are affected you cannot afford to wait for the strychnia to be absorbed by the stomach, but must give it hypodermically. You may give one or two injections daily of one eightieth of a grain each, which will have a good effect. Electricity is necessary and useful also, both the Faradic and galvanic currents. As far as this phase of the case goes, then, the prognosis is favorable, but there is a very unpleasant complication in the shape of the nephritis which has been alluded to before. The father says the child passes water as usual, but no dependence is to be placed on such statements; the only way in which you can obtain satisfactory and trustworthy information on the subject is by having the urine measured ounce by ounce. At the beginning of a case of nephritis the urine is diminished in quantity, but as the shrinkage of the kidney takes place there is passed a great quantity of urine of low specific gravity, ranging between 1004 and 1008. This child should go to bed, and ought to perspire freely once or twice a day; for that purpose either a hot-air bath may be used or the hot pack, or you may produce diaphoresis by the subcutaneous injection of pilocarpine, which will make the child perspire freely. This should be done two or three times in the twenty-four hours, but while he is perspiring you ought to give alcohol because the pilocarpine acts as a depressant on the heart's action. I have given as many as eight injections to a child of this age in the twenty-four hours, always seeing that the children were well stimulated, but I do not recommend this in every case. Each case, remember, is a case by itself, and requires its own special treatment, and he who has not the power of individualizing ought never to be a physician. Where the heart's action is good you may use pilocarpine. I have had a number of cases of Bright's disease after scarlatina get well on this treatment. Gallic and tannic acids, in doses of five to fifteen grains daily, act favorably also by restraining the loss of albumen, and may be given in connection with the pilocarpine. Iron is useful when there is much albumen in the urine towards the latter stages and many blood cells have

been destroyed. Strychnia internally, then, for this case, up to one twenty-fifth of a grain per diem, a hot bath twice a day, and the bowels to be kept gently open, not too much so. Purgation should be employed with caution in children, for the purgatives which are selected are the salines, and they act by diluting the blood, and they therefore require a certain amount of strength in order to be well borne.

HEADACHE.

BY WILLIAM INGALLS, M. D.

If any one care to investigate the subject of headache let him consult, as one authority, Wood's Practice of Medicine, volume ii., page 671. He will not find much encouragement of a practical nature from what he reads, I apprehend, if he have, as he should, an earnest desire for the restoration of his patient to health. I commend the searcher to the first line of the last paragraph on page 673, which reads: "The first and most important point is to discover and remove the cause."

The subject under consideration is Sick Headache or Idiopathic Headache, of which there are a great many examples, and as I have a theory as to the cause, and a speculation concerning the means of cure, I invite your attention to what I have to offer.

And first, I have written an outline record of several cases, all of which are pertinent to the subject, though not all of them strictly cases of sick headache: *e. g.*, the first.

Three years, between 1862 and 1866, were passed by the writer in the field, in the late war, a part of the time in the Carolinas and the remainder in Virginia, during which time many hundred men were under his care and observation, and it is not within his recollection that he was called upon to treat, or that there was reported to him for treatment, one case of idiopathic headache. The following is recorded and will be alluded to later.

CASE I. North Carolina, in 1863; a man of large frame, well nourished, strong, not obese, was brought to the hospital tent by his comrades with the report that he had suffered for about one hour an agonizing pain through his head, that upon arising to come to hospital for relief he fell heavily upon the ground, unconscious. His breathing was slow and labored, pulse large, strong, and not easily compressible, forehead damp, eyes injected, pupils noted, but not set down, and their state forgotten. He was immediately let blood to thirty ounces, and it was delightful to witness his returning consciousness. He fully recovered, and returned to duty in three days. He assured me that he did not remember ever to have had a headache before. It was set down as a simple meningitis or coup de soleil from hard work under a hot sun for three hours. He had been slaughtering cattle for the division.

CASE II. A banker, is now seventy years of age. Up to the age of thirty-six he enjoyed the best of health and strength, from that age to about that of fifty-three, he tells me, he suffered almost daily with severe headaches, oftentimes accompanied with distressing nausea. Treatment by various physicians was of no avail for permanent relief. Tea and coffee he had given up for several years, yet the headaches continued. He has

always attended to business. About seventeen years ago he went to Havana. As is the custom there, quite early in the morning a servant brought to him, while in bed, a cup of coffee; this was his first morning: the day before he had suffered the most cruel headache of all, and he would not drink it. The second morning, however, he drank the cup, and from that time to this he has never had a headache. He drinks coffee every morning.

CASE III. A married woman, aged forty, tall, well formed, of light complexion, has always been a worker; has been married sixteen years; her oldest child is thirteen and her two other children are ten years old; she had a miscarriage at two months, five years ago, is a house-keeper with love of order and neatness, in excess, which, as she keeps no servant, causes her great labor. Her children are almost entirely clothed by her own hands. Her husband is a skilled workman and must have his breakfast and be out of the house by seven o'clock; his dinner must be ready at ten minutes past noon. This is a mere outline of her life. To bed at ten, she rises at five. Note this: rarely does she go out of the house except as a matter of duty.

About seven years ago she awoke one morning with her first headache, which filled her with astonishment, so great was the pain, but as the day wore on the trouble diminished, and this is often the case with her. Headaches, sometimes with, and sometimes unaccompanied by, nausea, have pursued this patient all this time. The bodily functions for the most part are in good order. Occasionally there is a restless night, but generally sleep is sound and sometimes profound; quite frequently at the five o'clock awakening she is heavy with sleep, but the morning duties are, to her, inexorable, and there is no "folding of the hands." Since the miscarriage the headaches have been no more severe than they were before.

Five years ago this patient took a vacation of five weeks at her old home far down East. During the first two weeks there her headaches and her general misery were indescribable; but from that time an amendment took place, and she began to make visits and to ride and walk, and was free from suffering, and became well and strong. The amendment continued for a week or two after her resumption of her home duties, since which she has been as she was before. She is exempt from her malady about three fourteenths of the time.

CASE IV. A physician of this city died, at the age of sixty-two, in the year 1866. From the time of his graduation he was frequently assailed by severe headaches, rather infrequently accompanied by nausea. The attacks rarely began with the day, but often an hour or two after breakfast, and for several years they unfitted him for his duties for a large part of the day, and he felt obliged to go to bed, being utterly unable to preserve the erect position. He had light complexion and was, moreover, pale, at times white. His bodily functions were generally in order. Every course of living was adopted and continued for weeks or months, from a strictly bread-and-milk diet up to the most generous and liberal living. Drugs, also, at various times were used systematically and persistently. Tobacco he could not use in any form. In the last decade of his life this gentleman grew stout; in his earlier life he was thin and spare. He had for many years a fixed belief that he had some disease of the heart, but experts who ex-

amined him failed to discover any. In this last decade he did not suffer with headaches so often as before, but when they came on they were as intense.

He died of rupture of the left ventricle; he had fatty degeneration of the heart.

CASE V. A thin, spare man, forty years of age, has been tormented with headaches, sometimes accompanied by nausea, since he was fifteen years old. His complexion is dark and sometimes sallow. It is rare for a week to pass in which he is not disabled for twenty-four or more hours by a headache. Two years ago, he came under my professional care. The pain was throughout the head, and he had suffered from it for three hours previous to my first visit; the tongue was flabby and with a moist white coating, the pulse slow and compressible, stools not clay-colored, yet lighter in color than they should be. Small doses of calomel and rhubarb night and morning, and a vegetable tonic at noon-time were prescribed and followed up for three weeks, and there was amendment as to frequency and severity for three or four months. But the treatment is obliged to be repeated as often as two or three times a year. This gentleman was on active duty in the army for four years, and almost all the time in Virginia, during which he had not more than four or five attacks of his malady.

CASE VI. is that of a skilled machinist, by which I mean one who, in addition to his adroitness and willingness to work with his own hands, has the responsibility of seeing that the other workmen in his department do not go wrong, and who is the man to set them right when they do, and thus his head is pretty well at work as well as his hands. Headaches tormented this man while he was a youth; he is now forty-five; and he has toiled many a day when he thought it would be a good thing for the powerful engine to crush his head off. By degrees, the frequency of the attacks came to once a week, and, singularly enough, began on Saturday night and ended in the course of the following Monday. He was under my care for one year, four years ago; he received no permanent benefit. Electricity seemed at one time to lessen the severity, but did not prolong the intervals. I need not go into particulars as to his case. He is of dark complexion, sallow; slow in his movements. This, however, it is important to say, that when he can be driven from his work and sent into the country for three or four weeks he has no malady for two or three weeks after his return.

Case II., that of the banker, may be set down as one of the curiosities of medicine, for why he should have lost his tenacious companion of seventeen years so suddenly and never regained it is past finding out.

My theory in regard to the cause of sick headache in a vast proportion of instances meets with some support from Cases I., III., V., VI., and this it is, that those who lead an out-of-door life are *unapt* to be afflicted with that terrible malady.

The first case carries with it the fact that headache was never complained of by those living an out-of-door life, while backache, pain in joints and limbs were of constant occurrence. Case III. is one of a great many, it might almost be called typical, the woman doing the work of two, rarely taking out-of-door exercise, thus missing a wholesome sun and air bath, yet when away from care and work, and when, after a little, she becomes accustomed to her new life, she rallies into

sprightliness and strength, becoming vigorous enough to ride and walk, and to forget her old enemy, having no battle with him until she returns to her former habits. And so also of the machinist.

If the grand cause of sick headache is as has been stated, the remedy is patent. I have never known drugs or regimen to do any permanent good; and to urge the adoption of the almost certain curative we shall find, unhappily, few indeed who will be able, for obvious reasons, to make any sufficient change in their habits or in their ways of life.

SARCOMATOUS TUMOR OF ABDOMEN INVOLVING LEFT KIDNEY AND ALSO RIGHT KIDNEY IN A GIRL FOUR YEARS OLD; DEATH; AUTOPSY.

BY C. ELLERY STEDMAN, M. D., DORCHESTER.

A. C., four years old, began to be ill early in March, and I saw her on the 9th. She was listless, irritable, with capricious appetite, slept poorly, tired soon, and liked to lie on the floor face downwards; the belly was tumid, and the bowels regular; some nausea; no complaint of headache or other pain; the temperature about 99° F. in the morning and 102° F. in the evening. She remained about the same with slowly increasing emaciation and weakness. On the 19th, though there were no symptoms pointing to the kidneys, the urine was obtained and found to be normal in amount, containing one eighth per cent. of albumen and granular and hyaline casts; there was no hæmaturia during the course of the disease. It was now said that the patient had not been really well since January, and many circumstances were recalled confirming this belief. On the 29th swelling and dullness was noticed in the left hypochondrium. At nine p. m. of this day she was seized, without special cause, with a violent tonic convulsion, lasting two hours. The spasm was mostly confined to the right side; the temperature, 104° F., was reduced (by a bath cooled to 75°) to 100° F., and the fit yielded after two enemata of ten grains each of chloral. After the operation of a cathartic the belly became flaccid, and there were to be felt in the renal regions two tumors, the left nearly the size of a foetal head, the right apparently as large as a turkey's egg. The next day she had quite rallied from the convulsion, and appeared much as usual; emaciation progressed and strength failed. There was at no time discoloration of the skin. The tumor of the left side grew rapidly upwards towards and past the umbilicus, and downwards to the pelvic brim; œdema of the legs and body appeared. The abdominal veins were prominent. Percussion was dull over the tumor, which presented nodules and cysts to palpation. She suffered little or no pain, and went out in her carriage daily, spending many hours out-of-doors. On the 5th of June the appetite failed. On the 8th very little urine was passed, and none on the 10th, when, at half past nine, she died very quietly.

Drs. Edes, Thorndike, and Fifield saw her in consultation.

The autopsy was made on the 12th.

The body was very greatly emaciated. A tumor in the left side extending from the fourth rib to the pelvic brim, bulging out the back and flank, spread out

the ribs, pushed forwards the sternum, and crowded upon the left kidney. A pint of bloody serum was removed from the abdominal cavity. On the tumor, which occupied nearly all the abdomen, was flattened out the spleen in the upper left part, the pancreas spread thinly across the middle, while the colon traversed the growth three quarters of the way down, all adherent, the small intestines being pushed to the right, the lungs, not compressed and crepitant, were crowded into spaces the size of one's fist. The tumor was composed of a large cyst filled with grumous material, apparently composed of blood coagula, bloody serum, and more or less broken-down and ragged masses of fibrous tissue, apparently new growth. Attached to this cyst were smaller cysts, seemingly in the connective tissue, filled with bloody serum. There were several masses of white semi-fluid or denser matter, of which the principal was posterior and closely fixed to the vertebral column and adherent to the stomach and intestines. The cyst-walls were so much thinner than the adhesions that the tumor could not be removed entire, but was broken in many places. The left kidney was spread out on the surface of the mass; the pelvis, though distorted and compressed, appeared normal in structure, and could not be made out to communicate with any of the cysts. The cortical substance was thinned, a little paler than normal, adherent in small spots to a dense thickened capsule. In the renal substance itself there was *none* of the malignant growth. The tumor weighed, by estimate, seven pounds.

The right kidney was thrice its normal size, being $13 \times 7 \times 3.5$ cm., and perhaps one half its tissue preserved, there were in it several cancerous masses, compressing the renal substance, which in both kidneys was a little granular. The largest tumor in its substance was $7 \times 4.5 \times 3$ cm. near one end, the next was as large as a horse-chestnut; there were several others, large and small, all within the kidney parenchyma, and did not communicate with the pelvis; the larger ones possessed quite firm and distinct capsules; the contents were of moderate firmness, slightly yellow, with streaks of connective tissue here and there of a deeper yellow. The smaller masses had less distinct capsules, the contents being whitish and mucilaginous. The kidney substance was perhaps a little pale, at places compressed by the tumors, elsewhere the cortical substance was of nearly normal appearance. One mesenteric gland showed the only other appearance of cancerous disease.

Dr. Edes, who furnishes part of the above description, considers the microscopic appearances to be those of a small, round-celled sarcoma.

In the symptoms preceding the death of this patient, the absence of hæmaturia, which is present in the ratio of thirty-one out of fifty-nine cases of this disease was noticeable. No cancer cells were seen in the urine. Again, ascites was not observed till a week or ten days before death, at which time œdema of the legs and trunk set in. It has been said that dropsy in the abdomen without œdema of the legs is characteristic of malignant growths in the abdomen. The kind of cancer found in this case is the usual form; schirrous, colloid, and epithelioma are extremely rare. The large size of the growth is the rule. Robin mentions one tumor of kidney in a child weighing thirty-one pounds. In Roberts' sixty-eight cases "the disease was confined to one kidney sixty times, in seven both kidneys were involved, but in three only of these did the disease appear to be

primary on both sides, in the other four one kidney was the seat of primary cancer which formed a tumor, while its fellow only contained small secondary nodules. In the sixty unilateral cases of cancer each kidney was affected an equal number of times. "Twenty-two of these cases out of sixty-seven occurred in children under five years of age, three others between seven and ten, the remainder were distributed pretty equally between the ages of nineteen and twenty. . . . The male sex is more liable to renal cancer than the female, sixty-six cases being divided between forty-seven males and nineteen females, but the preponderance of the male sex is not so great in childhood." In this case there was scarcely any pain. The duration of the disease is supposed to have been four months.

REPORT ON PROGRESS OF OPHTHALMOLOGY.

BY O. F. WADSWORTH, M. D.

THE EYES OF THE NEW-BORN.

THE investigations of Jaeger¹ as to the refraction of the eyes of infants remained for a long time the only ones. In 1880 Ely² and Horstmann³ gave the results of their examinations in the same direction. Königstein⁴ also has examined the eyes of nearly three hundred infants. As the statements of the three former observers differed decidedly in regard to the character of the refraction found, so Königstein's statement differs much from either of theirs. It is of interest to compare these statements, as Königstein has done, and see how far it may be possible to account for the disagreements.

Jaeger, of 100 eyes of infants between 9 and 16 days old, found 17 hypermetropic, 5 emmetropic, 78 myopic; in 48 the myopia ranging from one twelfth to one sixth. Ely, in 154 eyes, up to 8 weeks of age, but nearly three fourths less than 2 weeks, found 69 per cent. hypermetropia, 14 per cent. emmetropia, 18 per cent. myopia. Horstmann, in 40 eyes less than 20 days old, 70 per cent. hypermetropia, 20 per cent. emmetropia, 10 per cent. myopia; the myopia only one half to one dioptré. Königstein, in nearly 600 eyes under 9 days, found only a few which might be called emmetropic, that is, with hypermetropia less than one fortieth; in all others there was hypermetropia, in many greater than one twelfth. Also in premature births the hypermetropia was greater than in children born at term.

Jaeger examined the infants lying on their backs, without dilatation of the pupil by atropine, the lids sometimes held open by a speculum, the eye sometimes held by forceps. He used the weak-light mirror. Under such unfavorable circumstances it must have been difficult not to make mistakes. Analysis of Jaeger's observations of older children serves still more to throw doubt on his results. He found among country girls of 5 to 11 years 56 per cent. myopia; among boys of 6 to 11 in an orphan asylum 55 per cent. myopia; children of 9 to 16 in a private school 80 per cent. myopia; thus differing greatly from all subsequent observers, almost no myopia being found in village schools in Germany, and even in universities

² Archives of Ophthalmology, vol. ix.

³ Bericht der Versammlung deutschen Naturforscher und Aerzte in Danzig, 1880. Centralblatt für pract. Augenheilkunde, 1880.

⁴ Medizinische Jahrbücher, 1881, Hft. 1.

no such percentage of myopia having been discovered as that given by Jaeger for children of 9 to 16 years.

Ely examined 105 eyes with pupils dilated by strong solution of atropine, his own eyes also atropinized. The infants were narcotized by paregoric, held erect by a nurse, and a sweetened rag or finger placed in their mouths. Of these only 11 per cent. were myopic. But another series of 19 eyes, with weak solution of atropine, without paregoric, and without atropine in the observer's eye, gave 33 per cent. of myopia. The two series together gave 18 per cent. of myopia. There is another peculiarity in Ely's cases. In 100 eyes of the first series, in children of one week and less, there was not quite 8 per cent. of myopia, from the first to the second week 25 per cent. myopia, and from the second to the eighth week no myopia. In the second series, in the first week 23 per cent., second week 35 per cent., second to eighth week 31 per cent. myopia.

Horstmann used atropine, but no detailed account of his method is at the disposal of the reporter.

Königstein used a weak solution of atropine, had the infant held against the shoulder of a nurse, a teat in its mouth, and raised the lid with his finger when necessary, as was usually the case. He believes that the infant's eye is almost invariably hypermetropic, but admits that his investigations were all among the lower classes, in whose eyes myopia is less common. In a note he adds he has learned that Horner has examined infants of the better class, and found only hypermetropia.

The color of the iris in the new-born is, according to the text-books, always blue. Ely always found it bluish, even in one negro, and Dr. Culpepper in fifty infants at the Charity Hospital saw only one, a negro, with brown iris. Ely also quotes one of the nurses at the Maternity Hospital as having seen in more than 1000 confinements only one infant with dark irides. Königstein considers the color rather gray, with a tinge of blue or green, and has seen several cases of dark-brown irides.

Remains of the pupillary membrane Königstein found in 21 infants among 281 in whom it was looked for, and thinks in some cases fine threads may have escaped him, and in others been broken by the use of atropine before examination. He agrees with Jaeger that in infants the optic nerve appears bluish gray, and states also that the difference between arteries and veins is not so pronounced as in adults, either as to color or size.

An important fact noted by Königstein was the frequency of hemorrhages in the retina. He saw them in 10 per cent. of the infants observed, both striated and rounded; often they were large and spread over a large extent of the fundus. They were absorbed rapidly, and in several cases he was able to watch the change and diminution day by day. The possibility is suggested that some of the larger hemorrhages, though disappearing without visible trace, may destroy retinal elements, and so be the cause of amblyopia without ophthalmoscopic changes found later in life. These retinal hemorrhages appear analogous to the ecchymoses in the skin and conjunctiva, and it might be natural to explain their occurrence by the great pressure exerted on the child during labor, but they were not more frequent in difficult forceps deliveries, in forehead presentations, or in large children, than in those of small size, or in premature births when the labor was proportionally easy and short. Königstein regards the

changes in the circulation and arterialization of the blood at birth as the cause of the hemorrhage.

PROPHYLAXIS OF OPHTHALMIA NEONATORUM.

Bacteria have been found in the secretion of blenor-rhea neonatorum, as in other serious inflammations of the conjunctiva, by many observers, and naturally in these days of antiseptic treatment various agents have been employed as means of disinfection in this disease. At the height of the inflammation, however, disinfection has not seemed to be always sufficient, but the prophylactic use of antiseptics has given excellent results. Haussmann, more than ten years ago, demonstrated the habitual presence of bacteria in the vaginal mucus. He now¹ calls attention to the fact that the character of the presentation and of the labor may influence the probability of infection of the conjunctiva of the infant and also the time at which it occurs. That while, as a rule, in head presentations the vaginal secretions will during labor merely smear the lashes and lids, and only when the latter are opened after birth be able to reach the conjunctiva, on the other hand, in face presentations, in attempts at extraction, etc., direct infection of the conjunctiva may be effected within the mother by the manipulations of the obstetrician. He believes this last method of infection, together with prolonged labor, may explain the occasionally reported cases in which swelling or inflammation of the conjunctiva has been observed immediately after birth, and holds that an ophthalmia is more likely to occur after face than head presentations. He advises washing the lids immediately after the child is born with a one per cent. solution of carbolic acid, and, in cases where direct infection may have been produced during labor, or the eyes have been opened before the lids have been washed, washing out of the eyes also with the same solution. His own experience with this treatment has been encouraging but not extensive.

At the Lying-In Hospital in Leipzig Credé² sought at first to avoid inflammation of the eyes of infants by making vaginal injections in all women affected with gonorrhoea or chronic vaginal catarrh, the injections being given during labor as often as every half hour. But as this method, though it lessened the number of children affected, proved by no means satisfactory, it was abandoned. The plan was then adopted of washing the eyes shortly after birth with water, placing a drop of a two per cent. solution of argentic nit. between the lids, and covering them for twenty-four hours with cooling compresses kept moistened with a two per cent. solution of salicylic acid. At first employed only with the infants of diseased mothers, this treatment was later extended to all cases, and with the result that of two hundred children so treated during six months not a single case of blenor-rhea appeared. One baby only had a light attack of conjunctivitis in one eye, and in this case the application of the solution of arg. nit. had been accidentally neglected. Credé admits that six months is too short a time wholly to exclude the influence of chance. His experience shows, however, that the important factor is not disinfection of the vagina, but of the eyes themselves.

Olshausen,³ at Halle, has tried prophylaxis for two years. The first fifteen months the eyes of the infants were washed out with a one per cent. solution of car-

¹ Centralblatt für Gynäkologie, 4 and 9, 1881.

² Archiv für Gynäkologie, xvii. 1.

³ Centralblatt für Gynäkologie, No. 2, 1881.

bolie acid after the cord was divided and the child washed. The percentage of cases of blenorrrhea was reduced from 12.5, the previous average amount, to 8.8. During the last nine months the lids were washed off with the carbolic-acid solution so soon as the head was born and before the eyes were opened, and then the eyes washed out with the solution also, and the per cent. of blenorrrhea fell to 3.6. The cases of blenorrrhea which did appear were also much milder, and in no instance was there injury of the cornea. He proposes to use a two per cent. solution of carbolic acid in future, one washing with which he states is harmless to the eyes. Though these results were not so striking as Credé's the treatment was a much simpler one, and Olshausen doubts whether the arg. nit. or the salicylic applications made by Credé were the more efficacious; moreover, the latter call for a close and continued care on the part of the attendants which cannot always be given. Further experience must determine the most reliable means of disinfection. He regards a blenorrrhea beginning later than the fifth day (it usually begins on the third or fourth) as probably to be referred to infection from the lochial discharge or from another child.

INFLUENCE OF DISTURBANCES OF THE CAROTID CIRCULATION ON THE EYE.

Michel¹ contributes an interesting paper on this subject. The conditions he found on ophthalmoscopic examination when digital compression of the carotid was made in man, or the carotid ligated in dogs, differed in many respects from those described by others. In man he saw in the eye of the same side paling of the papilla and narrowing of arteries and veins, which soon gave place to redness of the disc and venous hyperæmia. In the dog, on ligation of the carotid, in a very short time there was pallor of the disc and disappearance of blood from all retinal vessels, followed as quickly by sudden refilling. If the ligation was permanent the disc remained somewhat paler, the arteries somewhat narrower, while relatively the veins appeared wide, and this condition could be distinguished for weeks, though diminished in amount. While the primary pallor of the papilla and narrowness or emptiness of the vessels is due to the interruption of the blood current, and the subsequent filling to restoration of the current through collateral channels, the persistence of venous hyperæmia is ascribed to decreased arterial and consequent decreased intra-ocular pressure. As to the differences observed in man and the dog, the incomplete emptying of the vessels at first in man may be explained by incomplete closure of the carotid and probable freer collateral circulation; the subsequent reddening of the disc may point to a greater natural hindrance to venous outflow, which would be increased by the not wholly avoidable obstruction of some of the veins of the neck when digital compression is made.

From these and similar observations, clinical and experimental, and the considerations awakened by them, Michel deduces a new theory of the production of choked disc with intra-cranial new formations. He regards the first stage of choked disc (a high degree of venous engorgement, with apoplexies, and edema of the disc) as the consequence of venous hyperæmia, and the venous hyperæmia as produced by increased intra-cranial pressure. But while according to the theory advanced by

Von Graefe the excessive intra-cranial pressure acted to check the outflow of blood in the veins and thus caused venous stasis, Michel believes the effect of the pressure to be to hinder the inflow of blood through the arteries. The venous congestion in the eye is thus the result of the lessened arterial pressure, just as is the case when the carotid is compressed. Collections of fluid in the spaces between the nerve sheaths, or in that over the chiasma, etc., complicate the picture of venous stasis by exciting inflammatory processes in the nerve substance. "The choked disc is then the consequence of the altered circulation, it is complicated by the possibility of other added pathological changes."

Two cases are related in which disease of the carotid interfering with its circulation exercised a marked effect on the circulation and nutrition of the eye. One was a case of aneurismal dilatation of both carotids. The eyes were soft, the retinal arteries narrow, the veins wide and tortuous, there was serous exudation in a portion of the retina, impaired vision. The other case was one of thrombosis of the right carotid. Here the right eye was soft, its arteries narrow, veins wide, cedema of the retina, loss of sight.

Convinced that with great disturbance of the circulation through the carotid changes might be expected in the corresponding eye, Michel went further. He considered it possible that a disturbance of the circulation, characterized rather by long continuance and gradual increase than by sudden occurrence, might also give rise to impairment of nutrition in the eye. Prompted by this idea, he took careful note of the condition of the carotids in all cases of cataract, senile and other, of unknown origin. In the course of ten months fifty-three cases were observed, and in all a connection between the formation of opacity in the lens and sclerosis (atheroma) of the carotid is believed to have been undeniable. These cases are divided into four groups. (1.) Unioocular cataract, with sclerosis of the carotid developed only, or in much higher degree, on the same side. (2.) Double cataract, developed earlier or more advanced on the side on which sclerosis of the carotid was more pronounced. (3.) Double cataract, commencing at the same time or equally advanced in the two eyes, with equally marked sclerosis of the two carotids. (4.) Cataract with sclerosis of the carotid and also enlargement of the thyroid gland.

The age of the individuals affected ranged from eight to eighty-one years. In the first group were four from eight to seventeen years of age. The most striking cases, and those which have the most weight as evidence, are those in which, with youth and middle age, there was cataract in one eye only, and relative or absolute onesideness of the sclerosis of the carotid.

That the lens should be chiefly affected by diminution of the blood supply to the eye follows naturally enough from the fact that under normal conditions its nutrition is affected only indirectly. Michel does not assume, however, that with every senile or unioocular cataract sclerosis of the carotid must be present. Senile marasmus, as every marasmus after an exhausting disease, congenital narrowness of the arterial system, strumous swellings which compress the carotid, any of these may cause cataract, and examples in point are given of each. The lesson to be drawn is that in every case of opacity of the lens (aside, of course, from traumatic cataract, etc.) the state of the circulatory system should be examined.

Finally, Michel cites two cases in which anæmism of

¹ Beiträge zur Ophthalmologie als Festgabe Friedrich Horner. Wiesbaden, 1881.

the internal carotid produced pressure on and disease of the opticus. And he thinks that with continued attention to the subject the category of ocular affections caused by disease of the carotid will be further extended.

Hospital Practice and Clinical Memoranda.

CHILDREN'S HOSPITAL.

CASES IN THE SERVICE OF DR. E. H. BRADFORD.

REPORTED BY MR. JOHN TRUMBULL.

THREE CASES OF OSTEOCLASIS.

CASE I. H—, three and a half years, was referred to the hospital by Dr. Kinnear. The patient presented marked outward bowing of the tibiae, the distance between the internal condyles of femur on bringing the feet together being eight centimetres.

Under ether both tibiae and fibulae were fractured by means of the osteoclast three inches above the ankle, and the fragments being held in position the legs were encased in plaster. There was no rise of temperature above the normal, no pain or swelling of the toes. Within a fortnight a silicate bandage was substituted and continued for a couple of months, when they were removed, and the patient discharged with tibiae straightened.

CASE II. C—, three years, had considerable outward curving of both lower legs on entering. These were both broken with the osteoclast, and the limbs placed in a corrected position in plaster bandages. No trouble resulted from its immediate application, and the dressing was not disturbed for three weeks. Union of the bone was found, with the limbs in a straight position. A silicate bandage was applied to each limb, and the patient discharged, to report as an out-patient.

CASE III. K—, four years of age, was admitted with a rachitic curvature of both tibiae, forwards and outwards.

Both bones were fractured with the aid of the osteoclast a couple of inches above the ankle-joint, the deformity immediately corrected, and the limbs put up in a plaster bandage.

No pain or swelling followed the operation, and at the end of three weeks the plaster was removed and silicate bandages with steel bars applied. Discharged, and a month later reported with legs straight, and walking without difficulty. A slight tendency to turn the whole limb inward, the eversion occurring at the hip, was relieved by a suitable appliance, and the patient is now walking as actively as other children. During the recovery the patient was attacked by whooping-cough, which, however, did not interfere with the union of bone.

OSTEOTOMY FOR GENU VALGUM AND VARUM.

G—, colored, four and a half years old, entered with an extreme deformity of both knees (genu varum and valgum respectively). The patient was hardly able to stand. She was etherized July 29th, and under carbolic spray an incision was made, little more than an inch in length, along the inner side of the left femur above the condyle, and the chisels then driven completely through the femur. The wound was dressed antiseptically, and the leg held straight while a plaster

splint was applied from the toes to the upper portion of thigh. A window was cut out over the incision, its edges packed with putty, and Lister dressing applied.

No pain or swelling resulted, and the dressing was not disturbed till August 12th, when the wound was found to be healing nicely. Osteotomy of the right femur was performed as above, the incision, however, being made on the outer side.

August 24th both dressings were removed, as healing was complete in the left and nearly so in the right leg. Plaster also was removed from the former.

September 12th an attack of acute pneumonia set in, and it was four weeks before the child was well enough to be discharged, to report as an out-patient, with silicate dressings on, the result in the right leg being entirely satisfactory, while in the left there exists slight shortening, — half an inch, — with some prominence of the internal condyle.¹

FORCIBLE STRAIGHTENING OF DISTORTED KNEE AFTER CHRONIC DISEASE.

CASE I. T—, nine years old, entered with the results of chronic disease of both hip and knee. In the left hip there was slight motion, with slight adduction of the limb; while the knee on the same side was somewhat enlarged, tender, and flexed at about a right angle.

An attempt was made to bring down the knee by gradual straightening of a ham splint. This proving insufficient, ether was administered, and the leg straightened by forced flexion and extension. A silicate bandage, with a ham splint, was applied, adhesive plaster extension being also employed for a few days. With high shoe and crutches he was in ten days able to be about the wards, and was so discharged. No inflammation of the joint followed the surgical interference.

CASE II. D—, seven years, on admission, as the result of chronic knee-joint disease, had his left leg flexed at a right angle. He was etherized, both hamstring tendons divided, and the limb flexed and extended, fibrous adhesions giving way. The patella, however, remained adherent, and it was impossible to bring the leg straighter than within sixteen degrees of a fully extended position. A ham splint, with silicate bandages, was applied. Two weeks later he was able to walk about the wards on crutches, and was discharged wearing the ham splint.

TORTICOLLIS.

CASE I. T—, a girl nine years old, during an attack of rheumatic fever had severe spasms of pain in the head and neck, and next morning her head was found drawn over to the right side. Some improvement has since occurred, but nine months later she entered the hospital with her head twisted downwards on to the right shoulder, so that the axis of the face made an angle of twenty-five degrees with the axis of the body. Motion at the neck was impossible. The patient was in excellent health and free from pain. There was an evident lateral curvature, with marked rotation of the spine in the cervical region.

July 19th she was etherized, and after subcutaneously cutting the insertion of the left sterno-mastoid, which was prominent, extension and torsion were made

¹ This latter was due to the faulty position in which the limb was held when the plaster was applied. The deviation from the normal line was, however, slight.

upon the head, the shoulders being held. Adhesions were felt to give way. With a wire frame, taking support from a plaster jacket and holding the head by means of plaster and silicate bandages, the axis of the face was fixed in a corrected position. No ill effects followed the operation.

August 8th the frame was removed, and motion in either direction was found equally stiff. Four days later, under ether, the head was again twisted, the frame applied, and she was allowed to go home. A week later this was removed. Motion of the head was then allowed. The patient continued to gain, and became able to move the head in all directions with equal freedom. The head is held in nearly a normal position, although the axis of the nose varies from the vertical axis of the trunk a few degrees.¹

CASE II. J—, nine years old, entered the hospital for simple torticollis, with a firm contraction of the right sterno-mastoid. Tenotomy of both insertions of the sterno-mastoid was performed, a plaster jacket applied to the trunk and shoulder, and in this buckles inserted. Adhesive plasters and bandages were placed around the head, so as to secure it firmly, and by means of straps passing from the bandages around the head to the buckles in the gypsum bandage the distortion was over corrected. The patient remained in the hospital for ten days. Three weeks later the apparatus was removed, and the motions and position of the head were found nearly normal.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

M. M. RICHARDSON, M. D., SECRETARY.

JUNE 20, 1881. The Society came to order at 8 05 with DR. BROWN in the chair. The report of the secretary was read and accepted. Present thirty-six.

DR. INGALLS read a paper on

HEADACHE.²

DR. EDES said he had taken great interest in the subject of headaches because he had been subject to them himself ever since he could remember. He knew of no cause for them except fatigue. They last two days and go away on the third. They are less severe and less frequent than formerly. There are some remedies that will do good. Potassium bromide does good in his own cases. The best remedy in the severe headaches of interstitial nephritis is caffeine. In the use of coffee as a remedy in headaches it is the caffeine probably which affords relief. Many cases are relieved by three grains of caffeine once repeated.

DR. DRAPER confirmed what Dr. Edes had said. The fourth case reported by the reader is a good history of his own case. He had been a victim to sick headache all his life. A service of three years in the army did not modify them in frequency or in severity. They generally came on after overwork or exhaustion.

Among remedies, potassium bromide was most effectual, of late large doses of quinine seem best.

These sick headaches are very bad, sending a man to

bed for the day. One curious feature is that they often disappear with the setting of the sun. After suffering intensely during the day the patient may be able to do his work in the evening. Dr. Draper had had no experience with caffeine.

DR. BUNDY said that he had been one of the unfortunates, and had found relief in guarana; one drachm of the fluid extract is effectual, except when the headache is congestive, in which case he has used the bromide. He has found both remedies very valuable.

DR. EDES remarked that the active principle of guarana is caffeine.

DR. INGALLS said it was the cure of the disease he was after and not its relief. The relief is delightful but it is temporary.

DR. STEDMAN (C. E.) reported a case of headache in a married woman of thirty; poek-marked, who said that she had had a headache ever since she was four years old, with the exception of twelve to fourteen days when she was sick with small-pox. She wore a plaster on her breast, by which she thought the headache was somewhat relieved. In long-continuing cases of headache it is well to examine the urine.

DR. DENNY said, with regard to headaches in a medico-legal bearing, that in the case of Freeman headache was a prominent symptom for years before his crime. John Kember had severe headaches for years before he killed his three children. They were very marked while he was in prison. Subsequently, during his stay in jail, epileptic convulsions came on. In conjunction with epilepsy, headache exists oftentimes. In such cases he had found marked tenderness or hyperæsthesia in the region of the sutures of the skull, especially about the posterior fontanelle, and over the squamoparietal, coronal, and sagittal. Benjamin Eastman had these symptoms very marked, with headache. When suffering from them his intellect was clouded though at other times it was perfectly clear.

Williams, the Somerville murderer, presented similar symptoms for years, and his mother before him.

Lena Daniels, the infanticide, was subject for years to severe headaches. (Her father before her had sunstroke, which perhaps had some bearing on the headaches.) When under its influence she was very different in the manner of her responses to questions than when she was not. This was especially marked in the first days of her examination.

With reference to the effect of malaria on the production of headache, Dr. Denny said, that during the war sick headache was very seldom complained of. At least in North Carolina where malaria is very prevalent the symptom was almost unknown.

DR. C. E. STEDMAN reported a case of Sarcomatous Tumor of the Abdomen.³

PROCEEDINGS OF THE GYNÆCOLOGICAL SOCIETY OF BOSTON.

HENRY M. FIELD, M. D., SECRETARY.

GYNÆCIC SURGERY AT THE INTERNATIONAL MEDICAL CONGRESS.

STATED meeting first Thursday of October. PRESIDENT WHEELER in the chair.

DR. MARCY being called upon for his report of his visit to the International Medical Congress, commenced

¹ The case is one where the posterior muscles of the neck, not accessible to tenotomy, were more affected than the sterno-mastoid, which was not strongly contracted. Delore's method of forcible extension and torsion was the one chiefly instrumental in correcting the deformity.

² See page 439 of this number of the JOURNAL.

³ See page 440 of this number of the JOURNAL.

by saying, that to do any justice to the report upon Gynecic Surgery, that had been requested of him by the Society, it would be necessary to consider briefly the views advanced upon general wound treatment. No other question in the whole Congress equaled this in interest, and it is highly probable the importance of this subject is at present greater than any other in the entire domain of the medical art. This was first discussed in reference to abdominal surgery. The antiseptic method had many warm supporters: Dr. Keith stated that at first he was very enthusiastic as to its benefits, that after the adoption of the spray he had had eighty consecutive recoveries from ovariectomy, and had he stopped here he would have been a strong advocate of its value; but that in the next twenty-five cases he had had five deaths, two from carbolic poisoning, one from septicæmia, and two from acute nephritis. On account of this mortality, and of the frequent very high temperatures upon the evening following the operation, he had abandoned the spray; since, he had had one death in twenty-seven ovariectomies.

The discussion took a wide range upon the question of failure to obtain primary union in operation wounds and the methods best calculated to secure it. Mr. Savory, in a carefully prepared paper, drew the conclusion that primary union was most likely to occur when fresh surfaces are brought together in their natural state, and so maintained without disturbance. He believed the essential principles were rest, cleanliness, and asepsis; and these factors admit of a great variation in detail.

Mr. Gangee showed antiseptic absorbent cotton pads, which he had used with success. He illustrated their value by exhibiting a piece of perfectly preserved meat, which for twelve days had been enclosed between two of these pads, and had been exposed for a few seconds each day to the air. He emphasized perfect dryness of the wound, thus removing one of the conditions of putrefaction; rest; favorable position of parts; infrequent dressings with the use of antiseptics as an important adjunct.

Professor Esmarch detailed his own most remarkable experience. In 598 major operations there were only six deaths, and 85 per cent. of the cases cured healed by first intention with one dressing. These included 146 excisions of large tumors; 40 excisions of mammae and axillary glands; 51 major amputations; eight hernias; 19 compound fractures; etc. The cases were all dressed with pads soaked in iodoform and absolute alcohol (10 per cent.), fastened on by an iodoform bandage, over that a large pillow of jute and gauze, a moist dressing, and over all an elastic bandage.

Professor Volkmann believed that all suppuration is septic and, as is well known, holds antiseptic methods as a revolution in surgery.

Mr. Lister thought that, upon the whole, antiseptic ovariectomy had been successful, although he had attempted to dissuade Mr. Keith from using the spray, since his successes without it had been so very remarkable. He pointed out the care with which it should be used in abdominal operations, since here is abundant room for effusion and means of absorption, while carbolic acid both increases the one and lessens the other. He gave the results of a series of recent investigations, from which was demonstrated that blood clots in the body are less favorable to the development of organisms than the serum. "It is the solid bits of dirt that

are the deleterious agents," and he thinks it is very probable that too much attention has been given to the finer particles floating in the air. His own results were so good that he shrank from giving up any of the details by which he obtained them. He held to nothing by prejudice and was willing to give up the spray if better means could be devised; however, at present he could not accept irrigation as a substitute. The general condition of the patient and his surroundings must not be disregarded.

In military surgery, obstetrics, even in medicine, the subject of septic poisoning and antiseptic measures was held to be of the first importance and very widely discussed. Men of different belief would each obtain their crumb of comfort; however, the general verdict seemed to be entirely contrary to the spirit or inference derived from the interesting letter of our late lamented Professor Greene, published in the Boston Medical and Surgical Journal; and, briefly stated, the general impression produced was, that the general value of antiseptics is clearly recognized; while it was made evident that Professor Lister's aim may be obtained by other means, and that the successful operator must be the scientific surgeon of wide research, enlarged views, familiar with all the requirements of wound treatment.

Mr. Wells's paper upon the recent advances in the surgical treatment of intra-peritoneal tumors was of especial interest in emphasizing the value of a careful adaptation of the peritoneal surfaces, and this he illustrated by a series of specimens from various animals showing the variety of repair processes which ensue when the peritoneum is differently treated. He spoke of the difficulties in controlling hæmorrhage in the ablation of the uterus and removal of uterine tumors, and, as an aid of great value, exhibited a number of his large "pressure forceps" of various shapes. These differ from those ordinarily in use chiefly in size, greatly increasing the power of compression and the amount of material held by them. He uses antiseptic measures in all his operations, and has for a considerable period; he declared his belief that in abdominal operations the drainage tube should be used only exceptionally, in fact he had not used one for the last three years. "Since adopting antiseptic precautions either fluids do not form, or if they do they do not putrefy, they are absorbed without doing any harm, without leading even to any febrile rise of temperature." This quotation from his paper is of the greater importance since it is so directly opposite to the opinion of Mr. Keith.

Professor Tarnier, of Paris, read a paper upon the value of his obstetrical forceps, which was followed by an interesting discussion by Professor Lazarewitch, Dr. Fordyce Barker, Professor Simpson, Mathews Duncan, Dr. Barnes, Dr. Playfair, and others. The general conclusion was that they were of value, and in many instances to be much preferred.

Dr. R. Battey, of Rome, Ga., read a carefully-prepared paper upon his operation, which he calls Oöphorectomy. He distributed tables of his operations, and of the cases tabulated as complete operations there were cured sixty-eight cases or seventy-five per cent., greatly benefited, fifteen cases or seventeen per cent., not benefited, seven cases or eight per cent.; of the incomplete operations, greatly benefited, seven cases or forty-one per cent., not benefited, seven cases or forty-one per cent.

Dr. Savage, of Birmingham, read a paper giving a history of thirty consecutive successful oöphorectomies performed during the last two years for various conditions, ten being for long-standing and painful prolapse of the ovary, and four for myoma. For the benefit of these conditions he believed there was a wide field open for this operation in properly selected cases. With one exception — the inability to conceive — patients, after the operation, possess every attribute of womanhood.

Mr. Lawson Tait had operated twenty-six times for the lessening of fibroid tumors, with five deaths. He thought to control the menorrhagia, it was necessary to remove the Fallopian tubes also.

These papers were further discussed by Drs. Priestley, Thornton, Bantock, Hayward Smith, Mathews Duncan, Spencer Wells, Dr. Martin, of Berlin, Dr. Goodell, of Philadelphia, Dr. Pallen, of New York, and others. It was generally conceded that with proper selection of cases the operation was one to be recognized as justifiable, and an advance in surgery. Many things of the most complimentary character were said of Dr. Battey, who certainly shared generously the honors of the section.

Many papers must be passed without even reference in the brief period at disposal. Dr. Hewitt, discussing the exciting causes of hysteria, demonstrated his views, familiar to most of you, upon uterine flexions.

Dr. Mundé, of New York, read an interesting paper upon uterine displacements and their curability. After narrating the various means at the disposal of the surgeon, he gave as his opinion that pessaries well adjusted are by far the most valuable means, but that all methods, however wisely selected, must, in chronic cases, be persevered in for long periods before cure could be expected. Dr. Cole, of San Francisco, followed in a paper upon the same subject, and exhibited his pessaries as possessing exceptional value.

Professor Freund, of Strassburg, furnished an interesting paper upon the total extirpation of the uterus in malignant disease. The leaving open and drainage of the peritoneal cavity, the simple ligature of the vessels of the severed broad ligaments, step by step, made the operation shorter, less laborious, and hastened recovery. By separation of the cervix uteri from the vault of the vagina it is easy to draw up the uterus through the abdominal wound above the symphysis. This severing of the cervix he had performed before chloroforming his patient. The upward tension of the uterus held by the tenaculum forceps greatly lessened the hemorrhage; a fatal result in the hands of several operators was exceptional. In the early stages of malignant disease it may be undertaken as a not very dangerous operation with a promise of radical cure. If the uterus was very large and the vagina narrow, the abdominal operation was to be preferred.

Dr. Martin, of Berlin, said the operation was only available in a few cases because any cancerous affection of the broad ligaments or lymphatics rendered the operation useless. In six such cases operated on by himself all had died.

Dr. Nelson, of Chicago, urged the importance of the early recognition of cancer of the cervix, entered into a mild discussion of its causes, and advised the abdominal method of removal.

Dr. Barnes read a paper upon post-partum hemorrhage and its treatment, advocating the use of iron injections in extreme cases. This paper occupied an

exceptional period of time in discussion without eliciting very much that was new or valuable. Dr. Maddler, of Dublin, gave the views of his school, chiefly in favor of iron, and advocated the plan of Von Hecker, the hypodermic injection of large doses of sulphuric ether. Professor Winkel, of Dresden, also spoke of its value as restoring the heart's action and improving the tone of the blood-vessels.

Professor Spiegelberg, of Breslau, read a paper upon antiseptics in midwifery. The application and practice of Lister's system to the puerperium meant the strictest cleanliness and antiseptics during birth, both on the part of the persons attending the mother and the mother herself. Air must, as far as possible, be prevented from entering the genital tract, and since this was not wholly unavoidable, disinfection by frequent injections with antiseptics during birth should be used. After birth care must be taken to secure perfect rest of the genital tract, and if manipulation is necessary to do it with the strictest of antiseptic precautions. Professor Winkel stated that all the midwives under his direction had printed antiseptic rules. Carbolic solutions are used for all instruments, examinations, and workings.

Dr. Fancourt Barnes stated that in the London Lying-In Hospital all his patients were delivered under spray. In all examinations carbolic solutions were used. A one to eighty solution was used much of the time in the wards in atomizers. Since he had instituted the above precautions it was the exception to find any rise in temperature, while before the reverse obtained.

Professor Maggiotti (Rome) spoke highly of the value of iodoform as an antiseptic.

Dr. Eddis (London), Professor Lazewitch, and Dr. Tarnier all strongly advocated the value of antiseptic precautions in midwifery. Dr. Marcy urged the importance of early recognition of septic symptoms, and thereafter the immediate and thorough cleansing of the uterine cavity; the better to effect this purpose he had devised double rubber tubes of various sizes to No. 10 French scale. These were of easy and safe introduction, and gave a free and continuous outflow.

Dr. Pallen, of New York, read an interesting and highly original paper upon the reparative surgery of the genital tract, worthy of careful study, but time forbids an analysis of it.

The last paper of especial interest was by J. Henry Bennet, upon laceration of the cervix uteri, its causes and treatment. He carefully reviewed the whole subject, and called attention to the fact that in his work upon Uterine Inflammations, in 1849, he had pointed out the frequency of this lesion. He had attended during a long gynecological career hundreds of such cases of laceration without operating. An interesting discussion followed, in which the wisdom and benefit of Dr. Emmet's operation was clearly established.

We found Dr. Bennet a most interesting gentleman, and a day spent at his charming country seat at Weybridge, after the Congress, was one of the most pleasing episodes of our visit. The general interest in the sessions was kept undiminished until the close. The leading men of the different nationalities were constant in their attendance. Dr. McClintock presided over the section with a rare ease, grace, and dignity, while the spirit of the discussions was one of thoughtful earnestness, seeking to substantiate fact and advance the border lines of knowledge.

Only pleasant memories can be recalled by those

who were fortunate participants in this most remarkable medical meeting the world has ever witnessed.

Dr. MARTIN having previously given place to Dr. Marey, as his remarks would be less pertinent to matters of gynecological interest, now proceeded to address the Society.

Dr. Marey, he said, had been well repaid for his assiduous and faithful attendance upon the gynecological section, and had gained much that was new and important. He himself had not been so fortunate. When he had looked into that and certain other sections they were being addressed by French or German savans, and he was quite willing to acknowledge that the effort necessary to follow and imperfectly understand what they said was far from being rewarded by any very strikingly original or important information. It was very gratifying, however, to note the rapt attention and apparent interest of many of his compatriots to these, to himself, dimly dim and imperfectly instructive addresses. It was particularly illustrative of the immense educational advantages of international medical congresses, which some skeptics have seemed inclined to doubt, that most of these gentlemen had, previously to attendance at this particular Congress, been almost entirely ignorant of any modern tongue but their own.

There had been a vast amount presented to the Congress, the result of able, honest, hard scientific work, but there had been also, as there always is on such occasions, a great deal of rubbish, and he had been so unfortunate as to hear a good deal of this. As a general thing, the worthless matter came from men so eminent that they were eagerly and intensely listened to and applauded, no matter how flimsy or thousand times repeated their work might be, while much of the ablest and best work came from younger or less known men, to whom, no matter how admirable their efforts, but little attention or applause was vouchsafed. This is always the way, and always will be while the bulk of the profession pay far less regard and attention to the work done than to the person who does it. For himself, Dr. Martin could only express delight and gratitude for the innumerable courtesies and even distinctions extended to him from the very day of his landing in England to that of his departure six weeks later. Although, as before stated, he had nothing special to offer in gynecology, he had, while in England, been so fortunate as, long before the assemblage of the Congress, to make the acquaintance of Professor Lister. Then his attention was strongly directed to the considerations of the germ theory so far as it related to surgical practice and to the so-called antiseptic method. The very great courtesy extended to himself by Professor Lister certainly inclined him to a favorable opinion of anything which might claim him as an author or advocate.

He could not say, however, that his opinion, frequently expressed to this Society, of the germ theory of morbid inflammatory processes, and of the complicated method of treating wounds and performing surgical operations involving incisions, etc., had been changed or modified, except in being confirmed. Whilst he considered and fully appreciated the prominence which had been given to careful seclusion of wounds from the air, their being allowed to remain undisturbed for long periods of time, the means adopted to prevent putrefaction of secretions, mainly by careful provision for thorough and continual drainage, which we surely

largely owe in their present perfection to Lister's announcement of the germ theory, in connection with certain morbid surgical processes, Dr. Martin did not believe in the germ theory in the way, or to anything nearly approaching the degree, taught by Professor Lister and his more faithful and devoted disciples. If the practice is full of good, as he cheerfully and thankfully admitted, may it not be considered hypercritical to cavil at the theory to which, indirectly, we owe so much? Dr. Martin did not think so. When the theory that certain low forms of organic life are the sole cause of inflammation, and that varieties of inflammatory processes are each due to a different species of such organism, comes to be totally exploded, we shall be very apt to lose sight or full appreciation of the great advantages of a modified and reasonable practice of what is called the antiseptic method.

It has happened over and over again in the history of medicine that admirable points of treatment, associated with utterly exploded theories, have been swept into utter oblivion with the once widely popular theory which had led to, and been associated with, them. Those who have studied the history of our art, of the well-nigh innumerable, rapidly succeeding, and rapidly forgotten theories which have marked that history ever since the great iconoclast, Bombastes Paracelsus, smashed the highly respectable and venerable idols in the temple of Galen, will easily and readily appreciate the truth of this. To those who have not perused this extremely instructive study this is not the time to prove the fact. Nothing, however, could be easier; we need look no further back than the beginning of this century.

When Jenner stated the simple, fully-ascertained fact that casual inoculation of an *adult* human being with the virus from a certain vesicular eruption on the teats of the milch cow rendered the adult thus inoculated exempt from all danger of small-pox contagion, however conveyed, for the remainder of life, he announced a fully ascertained and infinitely important fact. When he also announced that inoculation of a second adult human being with virus obtained, at a certain stage, from the artificially induced disease, produced an apparently *precisely* similar effect, no one could doubt the interest and scientific importance of the discovery. When he asserted that virus obtained from vesicles in a human adult, being inoculated on a like subject, induced a disease precisely as protective of the patient from subsequent small-pox, he stated a *theory*, one very *probably* correct but not absolutely ascertained; by no means *proved*, either then or since. When he asserted that not only adults but infants inoculated with lymph taken after innumerable human removes from its original bovine source are thereby protected from small-pox in all degrees and forms for the remainder of life, exactly as the adult milker was proved to be completely protected, he started an essentially wild and really baseless theory, — a theory, however, regarded by the profession generally as absolutely ascertained. To doubt its truth involved for a long series of years such persecution as medical etiquette and professional magnanimity permitted, and to doubt and deny it, even twenty-five years ago, required great courage and indifference to consequences.

Now, however, whatever certain old fogies may think, no physician with any well-founded claim to consideration as a student of the subject, believes that there is no modification whatever in vaccine virus, re-

sulting from often repeated human transmission, or that the protection of one vaccination in infancy is as complete as that of an adult revaccinated with vaccinal effect, or as that of one first vaccinated successfully in adult life. What confusion and humiliation, what swallowing of one's thousand times uttered words or opinions, or even worse still, what angry and obstinate persistence in error, has grown out of the firm, unbending, unyielding faith of the profession (with rare and quite disregarded and despised exceptions) in *all* the doctrines of Jenner, not in so much of them as was based, really and logically, in the single ascertained fact of the permanent protection from small-pox of adult (over ten years of age) milkers by casual inoculation from the teats of the cow with the cow-pox, but on quite unproved, but very extremely *probable* surmises, the result, not of deduction from perfect premises, but of that reasoning from analogy, so fascinating to many minds, to that going from the particular to the general, which long ago one of the very wisest of the children of men declared to be a crying sin of physicians, and one which, more than any other, stood in the way of sound and true progress in medicine.

If, said Dr. Martin, the history of vaccination, of the thousand and one wild theories and suggestions to which Jenner's announcement gave rise, were investigated and considered, enough would be learned to make us hesitate before we accept all, or even a considerable part, of the theories already founded on the really very important, ascertained facts as to the rapid multiplication of certain low organisms and their agency in the production of certain diseased conditions.

The speaker had been led on far beyond the intended limits of remark on the subject. He had no doubt that antiseptic treatment, in a form much modified from what is now practiced by the Listerian, will have a continued and assured place in the surgery of the future. He could not doubt that Professor Lister deserved, as indeed he had received, the warm grateful applause of the profession and humanity for what he has done to establish and maintain antiseptic surgery, but he must continue to believe that much of the germ theory will crumble away into oblivion and discredit, and that the process will not be unassociated with a good deal of chagrin and humiliation to those who have so confidently and uncompromisingly assumed that it was "one complete and perfect chrysolite" of truth and of the result of sound logical reasoning.

The subject is a great one — too great to be lightly discussed. He hoped, as it concerned gynecological with all other branches of surgery, the Society would make it the subject of discussion for one or more sessions. Such ample time was absolutely necessary to anything like a fair and useful presentment of what might be said for and against the relations of the development and multiplication of certain low forms of organic life to surgery and the methods of treatment which that assumed relation has inspired.

ESSEX NORTH DISTRICT MEDICAL SOCIETY.

REPORTED BY DR. E. P. HURD, CORRESPONDING SECRETARY.

THE semi-annual meeting of the Essex North District Medical Society was held at the Eagle House in Haverhill, Wednesday, October 12, 1881. The president, DR. JOHN CROWELL, of Haverhill, in the chair.

DR. CHENEY reported an interesting case of Ova-

rian Dropsy where cure was accomplished by natural processes (absorption and elimination) without recourse to surgery. He also called attention to the beneficial effects of sodium salicylate in the treatment of typhoid fever.

DR. LOVEJOY read extracts from an article on the Use of Hypodermic Injections of Morphia in Puerperal Convulsions; followed by a discussion. The question was raised whether morphia suspends uterine action. The sentiment of the meeting was in the negative. Is the treatment of puerperal convulsions by subcutaneous injections of morphia *good* treatment? The answer was considered doubtful; anaesthetics and chloral seemed to give better results.

DR. TOWLE reported a case of Congenital Imperforate Rectum.

DR. ROOT reported a case of Hepatization of the Lungs in a child ten years old.

DR. TOWLE gave an interesting account of his recent illness in London. — passive pulmonary congestion relieved by hemorrhages, free and frequent.

DR. C. D. HENKING, of Haverhill, read a paper on Pneumonia; its Character and Treatment. He adopted the theory first proposed by Dr. William H. Draper, of New York,¹ advocated by Jurgensen, notably in this country by Dr. Austin Flint,² that Pneumonitis is an essential fever, and not purely a local inflammation. In other words, "the pulmonary lesion is a sequence in point of time of the pyrexia," representing "a conservative process by which a materies morbi is eliminated from the circulation," and is the result of a specific poison, allied to the poison of scarlet fever, small-pox, or typhoid fever, in the blood of persons suffering from the disease. In proof of this view (1) it cannot be induced by local causes, such as penetrating wounds, contusions, etc.; (2) cannot be induced experimentally; (3) has definite cycles and runs its course like the so-called essential fevers. If this view of the pathology of pneumonia is correct, it is evident that the treatment should be supporting and eliminating; the heart especially should be sustained by stimulants and digitalis; antimony and venesection should be discarded. The reduction of excessive temperature by cold baths and quinine was advocated by the writer. The essay was discussed by Drs. William Cogswell, R. C. Huse, and others.

Appropriate resolutions on the death of Dr. Martin Root,³ of Byfield, formerly secretary and one of the principal founders of the Essex North District Medical Society, were adopted; and the death of two of the senior members of the society was announced, namely, Dr. G. M. Garland, of Lawrence (died May 5, 1881), and Dr. W. H. Kimball, of Andover (died September 30, 1881).

¹ Bulletin of the New York Academy of Medicine, vol. ii. 1866.
² Practice of Medicine, Fourth Edition New York Medical Record, vol. xii., p. 443.

³ We publish below the resolutions, with the following synopsis of the preamble, which, in its entirety, is too lengthy for our columns.

Dr. Martin Root died of old age at his residence in Byfield, October 27, 1880, aged 78 years.

He studied medicine in Castleton, Vt., graduating in 1827. Settled in Byfield in 1828, joining the Massachusetts Medical Society about this time. In 1842 he helped found the Essex North District Medical Society, becoming permanent secretary in 1845, afterwards secretary and treasurer, till 1874. He never missed but one meeting of the District Society for over thirty years! In 1874 he resigned his office on account of failing eyesight and other infirmities; resolutions of esteem and confidence were passed, and he was voted a gift of fifty dollars from the Society treasury. Dr. Root left six children, one of whom is a physician, Dr. R. B. Root, of Georgetown, Mass.

As a physician he was popular and successful; he was conscientious.

Recent Literature.

A Treatise on Comparative Embryology. By FRANCIS M. BALFOUR. Vol. II. London: McMillan & Co. 1881. Price \$5.25.

WE are very glad to welcome Mr. Balfour's second volume, which completes his invaluable manual of comparative embryology. It is a bulky volume of nearly 700 pages. The first half is devoted to the completion of the first part of the work, (systematic embryology), and is accordingly occupied with chapters on *Amphioxus*, the *Tunicata*, and the several classes of vertebrates. The second half of the present volume contains Part II., *Organogeny*. It deals almost exclusively with the comparative morphology of the vertebrata, the author holding that "our knowledge of the development of the organs in most of the invertebrate groups is so meagre that it would not be profitable to attempt to treat systematically the organogeny of the whole animal kingdom." We know of no other work in which the problems of vertebrate morphology are so ably and philosophically presented and discussed. The manner in which he has brought out the essential features of vertebrate structure is very striking, and his work cannot fail to exercise a profound influence on the progress of anatomical and embryological research. To the English-speaking scientists the convenience will, of course, be particularly great. It is certainly gratifying to have a manual in our own language equal to the very best of German text-books. Indeed, Balfour's book is an abler production than Kolliker's *Entwicklungsgeschichte*, with which one naturally compares it, especially if we consider that the clearness and conciseness of the English work renders the tedium of the diffuse style of the Wurzburg Professor more offensive by comparison.

The chapters in the first half of the volume take up the classes of the *Chordata* in systematic order, an improvement on the pell-mell arrangement of the first volume. They one and all betoken Mr. Balfour's fitness for the difficult labor he has undertaken. The selection of what to present, the correct estimation of the relative value of conflicting observations and theories, and the relegation of the less trustworthy conclusions to a subordinate place, required an unusual insight and discrimination. The author, while following out all the latest advances in embryology and the newest and most startling deductions, exhibits a fortunate independence of judgment, for he is neither hampered by traditional opinions nor yet carried away by over eagerness for innovation. His pages are, moreover, enriched by original observations and mor-

phological conceptions at once new and philosophical.

If we should enter upon a detailed criticism of the work, we should produce a rather monotonous eulogium, although there are several respects in which we think changes or additions would result in improvement. Thus the primitive histological characteristic of the germinal layers is nowhere clearly brought forward. There is a neglect to take advantage of Hatches's very important work on the homologies of larval forms. More figures of whole embryos, and more reliance upon the results to be obtained by dissection of embryos, are to be recommended. The lungs and liver should have a much fuller treatment.

As a whole, the second volume is better than the first, not only because the subjects have been more fully investigated, but also because the author's handling has improved with experience, and he has profited by some of the criticisms passed upon the first volume.

The labor of preparing this work has been enormous and extremely difficult, but the result is so excellent and valuable that the author has placed all biologists and anatomists in his debt. Balfour's Embryology is a standard work, with which every student of zoölogy, and every investigator of anatomy, ought to be familiar.

C. S. M.

Photographic Illustrations of Cutaneous Syphilis. By GEORGE HENRY FOX, A. M., M. D. New York: E. B. Treat, No. 757 Broadway.

These three numbers complete the series of forty-eight plates, "photographed from life and colored by hand," and portray excellently the various syphilodermata. We have called attention at various times to the previous nine parts as they appeared, and while we did not feel authorized to indulge in the fulsome adulation expressed by some reviewers of emotional temperaments rather than minds judicial, our criticisms have yet been on the whole quite favorable. That to which we took occasion especially to object was the inferiority of succeeding to the first, and, as it were, specimen, numbers. Also the marked difference existing between different plates of the same case, the artist's work varying in its degrees of merit. These three concluding numbers are, however, as we said above, excellent. Dr. Fox is to be congratulated upon the successful accomplishment of a work which must have involved the expenditure of much time and effort by himself personally, while his promptness and regularity in issuing all the parts of the series is worthy of sincere commendation.

Part X. consists of five plates representing the ulcerative forms of the syphilodermata, and of these there is but one plate which is not exceptionally good. Part XI. comprises seven plates, large and small, portraying loss of nose; extensive ulceration due to chancrels; two primary lesions of syphilis, that is, initial indurations; periadenitis; and the syphilitic and non-syphilitic forms of condylomata. Part XII. concludes the series, and contains four fine plates of hereditary syphilis, and four smaller ones of syphilitic dactylitis, which, being dependent for their accuracy upon the camera rather than upon the artist are, of course, well given.

The series is not made up of exactly the illustra-

ties, and faithful in the discharge of every duty; in private life and in public, in every good work and word."

It was, that in the death of Dr. Martin Root, of Byfield, we were enabled to select an esteemed and valuable member of our Society, whose life was devoted to its interests, and was ever careful of the honor of the profession to which he belonged; one who in his long and useful connection with the Essex North District Society as its president, and in the discharge of his duties, had shown a high degree of fidelity, energy, and integrity, and to secure the continuance of his services, and the benefit of his example, we were enabled to select a successor, one who was a great help to the Society, and who, since his death, has been a great help to the Society, and who, since his death, has been a great help to the Society.

And it was, that in the death of Dr. Martin Root, of Byfield, we were enabled to select an esteemed and valuable member of our Society, whose life was devoted to its interests, and was ever careful of the honor of the profession to which he belonged; one who in his long and useful connection with the Essex North District Society as its president, and in the discharge of his duties, had shown a high degree of fidelity, energy, and integrity, and to secure the continuance of his services, and the benefit of his example, we were enabled to select a successor, one who was a great help to the Society, and who, since his death, has been a great help to the Society.

tions announced in the publisher's list; but the ones furnished are, as to subjects, equally well selected, and have been no doubt preferred as being finer in execution than the ones originally promised. The whole book is a treatise upon syphilis with illustrations, rather than plates of cases with accounts of the same, and is all the more valuable for that reason. A true list of illustrations is appended, together with a table of contents; also condensed notes upon the cases by number; finally, a well-selected formulary, arranged upon the metric system, as every scientific work of to-day ought to be, has been compiled and inserted, and will be appreciated by every busy practitioner of medicine.

E. W.

A Manual of Practical Normal Histology. By T. MITCHELL PRUDDEN, M. D., Director of the Physiological and Pathological Laboratory of the Alumni Association of the College of Physicians and Surgeons, New York, etc. New York: G. P. Putnam's Sons. 1881.

Histological manuals have multiplied of late with such rapidity that when we took up this little volume we were by no means disposed to welcome it, but on a closer acquaintance our preconceived aversion disappeared, and we are happy to find that a really valuable addition has been made to literature. The work is not merely a treatise on methods; it gives also brief accounts of the structure of the tissue and organs. The author is evidently a master of his craft, and fully understands the practical details. We are surprised at the amount of information put into such small compass.

Medical and Surgical Journal.

THURSDAY, NOVEMBER 10, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

BOSTON MEDICAL LIBRARY ASSOCIATION.

WE call the attention of our readers to the final appeal of the Medical Library Association on another page, and trust that it will meet with the ready response which it deserves.

It is now about six years since the library was first started in two small rooms in Hamilton Place, with scarcely any books, without a dollar, in the face of lukewarmness and great skepticism on the part of many influential members of the profession as to the possibility of carrying out the plan, and backed only by the faith of a minority that the physicians of a city like Boston could and would support a special library of their own in no less degree than its lawyers and its clergymen. That this faith was well grounded subsequent events have shown.

The Association now—within six years of its birth—has a membership of over 200, occupies and owns a building of its own, which is assessed for upwards of \$20,000, is admirably situated and adapted to its purposes, and contains a fine hall in which the meetings of all the local medical societies are held. It is regularly in receipt of 273 medical periodicals, has a reference library of more than 10,000 volumes and nearly 6000 pamphlets, and a circulating library of over 2200 volumes, with a cross reference card-catalogue of all, which is approaching completion. The Association carries on and gives a home to a Directory for Nurses, now about to enter on the third year of its existence, and this has already proved an immense boon to the medical profession and the public alike. Through its instrumentality a competent nurse for any case of illness can be secured promptly at all hours of the day and night for a very small fee, with full information as to her character, qualifications, price, etc.; and it was the existence of the medical library in a building of its own which alone rendered the establishment of such a Directory possible. The need had long been felt, and frequent attempts had been made to supply it, but the nurses could not be induced to cooperate in a scheme which savored to their minds too much of the intelligence office, while they were not slow to appreciate the advantages of the plan when taken up and carried out by the medical profession. There is scarcely a desirable nurse in the city of Boston or its immediate neighborhood who is not registered in the books of the Directory, and during the last year about 900 applications for nurses have been filed.

The Association, again, has received by donation a valuable nucleus of a collection of surgical instruments, which are loaned to members as required. In short, the aim of the management has been to make the library a medical centre, and useful in as many ways as possible to the members of the profession, and to the general public, not only in Boston but also in all parts of the State. The Directory for Nurses, indeed, is proving of service to all parts of New England.

If free from debt the Association would have an income of about three thousand dollars per annum, a sum sufficient to enable it to meet all reasonable expectations of the profession and of the public; but the interest charges and the reduction of the principal of the debt have necessitated the strictest economy in the past in order to make both ends meet. We trust that each member of the profession will see his interest as well as his duty in contributing according to his ability toward the fifteen thousand dollars which are asked for. A generous response from the profession itself will encourage generous friends outside of the profession, and the work of the Medical Library will immediately and once for all be put on a perfectly secure basis.

In the course of time the library will doubtless be endowed, members of the profession remembering it in their wills, but the receipt of the sum now asked for will obviate the necessity of any further direct appeal.

THE RADICAL CURE OF CANCER.

THE offer of prizes for essays on the Radical Cure of Cancer, to be found in the advertising columns of this Journal, will probably excite various phases of thought among our readers. Undoubtedly there is a certain proportion of medical men to whose minds the idea of instituting a search for a cure for cancer will not appeal very strongly. The belief that disease is a part of the plan of creation, and that, therefore, there will always exist pathological conditions beyond the avail of remedial agents, has a goodly proportion of adherents. Considered incurable (at least by medicine) before the time of Ovid, — "*utque malum late solum inmedicabile cancer serpere*," — the tone of discouragement being echoed by Monroe, Le Dran, Sharpe, and other physicians of note, cancer, it must be confessed, remains one of the chief *opprobria* of medicine. Nevertheless, there are those eminent in the practice of the medical and surgical art, as well as for their scientific attainments, who, in the matter of the possibility of curing cancer, have ranged themselves in the ranks of the less skeptical. It is only necessary to refer to the quotation from Sir James Paget's remarks in the discussion on cancer in the Pathological Society of London to show the truth of our statement. "If," says this distinguished man, "I look, and I do look, for a [remedial] hope of recovery from cancer," etc. As a matter of fact, Sir James Paget, in announcing this hope, echoes the implied, if not the expressed, belief of a large body of medical men for several hundred years. From the time, in the tenth or eleventh century, when Theodoric, the monk, extolled the internal use of arsenious acid as a cure for cancer, to the present day, the claim of the radical efficacy of certain drugs in this disease has always awakened the liveliest interest in the profession. The failure of the monk's remedy did not prevent Storck and Récamier from believing firmly in the curative powers of conium; nor did the non-fulfillment of the hopes raised by these two experimenters serve to diminish the eagerness with which, a few months ago, physicians beset the druggists' shops for long-forgotten jars of Chian turpentine.

There is thus, in the medical profession, evidence of an abiding hope, amounting to faith, of the possibility of the discovery of a radical cure for cancer; and we trust that the generosity of the donor of these prizes will be the means of bringing forward suggestions worthy of serious consideration.

The answer to the possible inquiry, what forms of morbid growths it is intended to include under the denomination cancer, is given, substantially, in the announcement. The term "malignant disease" has been employed, and this is intended to embrace, in a comprehensive way, all those forms of growth which possess infectious qualities, whether of an epithelial, connective tissue, or other anatomical character. It is rather the clinical aspect of the disease which is to be considered, and therefore even the growths of a lesser type of malignancy must be kept in view; for while these can, in the vast majority of instances, be controlled by sur-

gical art, they may, under certain unfavorable conditions, assume a highly infectious character.

We invite, then, earnest attention to the offer of these prizes, and we commend to consideration a quotation from Christopher Turner Johnson: "To view a disease as incurable is, in effect, to render it such, for, where this idea has unfortunately taken possession of the mind, the necessary result is a state either of dull stupidity, or of supine indolence. It is the generous hope of future discovery that will best serve to animate and lead us forward, in every scientific pursuit."¹

THE INDEX MEDICUS.

THE *Index Medicus* is a periodical which has reflected great credit upon American medicine; it is, as its name indicates, an index to medical literature, published monthly, giving the titles, properly classified, to original articles in the medical periodicals of the preceding month. Its use is, of course, mostly limited to physicians who desire to keep themselves specially informed on certain topics, and who have the means of consulting those journals referred to as containing articles of special interest to themselves. But if its use is limited to a comparatively small number of men, its influence is felt through the whole field of medicine. It is easy by its means for any man to keep himself well informed on what is being written; it is a great saver of time. It is a great addition to the armamentarium of medical libraries, and has received many encomiums from very various quarters; but this moral support by no means compensates for the paucity of *bonâ fide* subscriptions. It has been supported through the present year by private contributions, and the publisher is obliged to ask the support of the profession for the coming year. In a circular just issued he says: —

"The publisher cannot, in justice to himself, stand the risk of additional loss, nor does he feel justified in expecting the same small minority, who came so generously to the rescue this year, to bear the burden of the deficit a second time.

"While he cannot object to any individual contribution that may be directly pledged, he is unwilling to make any special appeal, believing that the enterprise is of such importance to medical science as to entitle it, on the part of the profession, to a more general support. If the general practitioner has no direct use for the *Index*, he is, nevertheless, indirectly benefited by its work. The publisher is at a loss to devise any means by which to impress this fact on those too busy to realize it, but he believes that in some measure a more general estimate of the work, and a more adequate cooperation on behalf of its support, could be insured through the medical organizations. Four associations, indeed, have already taken action in this direction, namely, the American Medical Association, the Philadelphia County Medical Society, the Philadelphia Pathological Society, and the Philadelphia

¹ A Practical Essay on Cancer. Annual Prize Essay of the Royal College of Surgeons of London for 1898.

Obstetrical Society, each of which subscribed fifty dollars toward the guarantee fund of 1881. If this example could be followed proportionately by other medical societies, the deficit could be covered with a minimum tax on individual members. Subscriptions by societies certainly divide the expense most evenly among the profession and seem the most desirable method of sustaining this enterprise, which is too good to die—we sincerely hope it will not prove too good to live.

EXPERIMENTAL PHYSIOLOGY.

THOSE who may be disposed to follow the example of England and seek to impose prohibitory restrictions upon experimental physiology, even in the hands of educated men, would do well to read the address of Mr. John Simon, delivered at the recent Medical Congress in London.

On another page our readers will find some copious extracts from this address, which we should have been glad to give entire did our space permit. Mr. Simon puts his side of this subject—which is our own—very clearly and very strongly.

MEDICAL NOTES.

—The Massachusetts Medical Benevolent Society had an agreeable social reunion at the house of its President, Dr. H. W. Williams, Thursday evening, November 3d. At the business meeting preceding the social entertainment the old officers were reelected with the exception of a change in three of the trustees.

—Professor H. J. Bigelow, and his son, Dr. W. S. Bigelow, arrived at home from England a few days ago. Professor Bigelow is one of the last of the attendants upon the International Medical Congress to return. We congratulate him upon the appreciative attention and interest excited among the surgical delegates by his modifications in the operation for lithotomy. These were subsequently the subject of two elaborate papers in the *Lancet* copiously illustrated by cuts.

—The notice of the first meeting, after vacation, of the Clinical Society of London, in the *British Medical Journal*, reminds us of the nominations by the Council of the International Congress of a few representative even as honorary members of that Society:

“The first meeting of the Clinical Society after the autumn vacation took place on Friday, October 14th. There was a good attendance of members, and the chair was taken by the President of the Society, Mr. Lister. After the reading of the minutes of the preceding meeting, the President announced that the Council had decided to recommend the Society to commemorate the recent meeting in London of the International Medical Congress by the election of several honorary members of the Society. The names of the distinguished persons recommended for such election were the following: Sir James Paget, the President of the Congress, and the second president of the Clinical Society, the only British subject proposed for the honorary membership; Dr. H. J. Bigelow, Pro-

fessor of Surgery in Harvard University, and Dr. J. S. Billings, of the United States Army, representatives of America; Professor Esmarch, of Kiel, and Professor Volkmann, of Halle, representing Germany; Dr. Vernetil, Professor Ollier, and M. Pasteur, representing France; and Dr. Pantaleoni and Professor Mazzoni, representatives of Italy. In mentioning the name of M. Pasteur, the President remarked that he was not, strictly speaking, a medical man, but that his distinguished services to medicine would be held as more than ample to qualify him for the proposed honor. The mention of the above names received the cordial approval of the members present, but the election of the honorary members cannot take place until after the required interval.”

—A new building has been fully determined upon for the Boston Dispensary. The additional sum of fifty thousand dollars is requisite to complete its fund. Eleven subscriptions of one thousand dollars each have already been obtained.

—A few changes and additions are to be noticed in the list of instructors in the Harvard University Medical School, as published in the schedule, as follows: E. N. Whittier, M. D., instructor in theory and practice; G. M. Garland, M. D., instructor in clinical medicine; F. A. Harris, M. D., demonstrator of medico-legal examinations; E. H. Bradford, M. D., assistant in clinical surgery. Special instruction is to be given by the following gentlemen: J. R. Chadwick, M. D., in diseases of women; T. B. Curtis, M. D., in diseases of the urinary organs; O. F. Wadsworth, M. D., in ophthalmoscopy; and J. Homans, M. D., in the diagnosis and treatment of ovarian tumors.

—On Saturday last there were nine cases of small-pox in hospital.

—A physician of Erie, Pennsylvania, is training carrier pigeons for use in his practice. He leaves pigeons at places from which he wishes reports to be sent him.

—A great increase in the cost of treating hospital patients has taken place in the last dozen years. In 1867, in St. George's Hospital, each patient cost £4 17s. 9d., increased last year (1880) to £6 17s. 3d., as we learn from the *Medical Times and Gazette*.

—The arrangements for the festival in honor of the twenty-fifth anniversary of Virchow's appointment as Professor to the University of Berlin—an anniversary which coincides with his sixtieth birthday—are now being made. The 19th of November has been fixed for this festival. The most interesting part of the proceedings will be the handing over to Professor Virchow the title-deeds of a new institution to be devoted to the prosecution of scientific researches especially relating to anthropology, of which he will have the full control. As a politician, an anthropologist, and an antiquarian, no less than as a pathologist, Professor Virchow has claims, not on Germany alone, but on the whole of civilized humanity; and we heartily join in the desire to do him honor.

—Frequenters of the Medical Library have learned to appreciate Dr. Neale's Medical Digest. It is a classified index to a large portion of the medical peri-

medical literature for the past thirty years. A second edition is in course of publication, which is to be even more complete and valuable than the first edition. It is to be published by subscription. The first edition was published by the Sydenham Society.

— A gentleman of Milan, Signor Lorin, has offered 20,000 francs to the municipal authorities of that city to maintain a mortuary and post-mortem room in connection with the crematory, wherein the bodies of all persons dying of unexplained causes shall be rigidly examined before they are cremated. This is indispensable if special facilities for poisoners and other murderers by secret processes are not to be created by the recourse to cremation.

— Professor Ira Remsen of the Johns Hopkins University is in Boston and is engaged upon an examination of the water. We fear the results must be of a negative character.

— Mayor Latrobe, of Baltimore, has signed an ordinance absolutely prohibiting the sale of toy pistols in that city. The large number of deaths by lockjaw last summer prompted the passing of the act.

— The London Sanitary Protection Association, which was organized about a year since, lately announced its first general meeting, when Professor Fleeming was to give an account of work already done. Professor Huxley is chairman of the Association, and Drs. Acland, Britowe, Andrew Clark, Burdon-Sanderson, Sir William Gull are, among others, members of its council. The convenience, economy, and utility of these associations are destined, we think, to make themselves felt in all cities and thickly settled towns.

NEW YORK.

— The Rev. Dr. John Hall has been elected Chancellor of the University of the City of New York in place of Dr. Howard Crosby, resigned.

— The fifth annual commencement of the Nurses' Training School at the Charity Hospital on Blackwell's Island took place on the 27th of October. Diplomas were conferred on seventeen graduates, three of whom read essays, a number of prizes were awarded, and an address to the class was made by Dr. Fessenden N. Oels. One of the essays was on Emergencies, another on The Care of the Sick, and the third was of a valedictory character.

Miscellany.

PERINEAL SUTURES.

ROBERT B. DEXON, M. D.

When a perineum is torn at the time of child-birth the proper thing to do is to sew it up at once, unless there is some grave contra-indication, as extreme exhaustion or very severe hemorrhage. If the tear should be extremely deep, through the sphincter and involving the rectum, it may then be well to let it go for six weeks or more, till the woman is in good condition for a secondary operation, when a better result will probably be obtained than would have been if the operation had been done primarily.

Many experienced practitioners never sew up a torn

perineum, or even examine to see if the perineum is all right. But when they learn that there is a tear, all that is considered necessary is to tie the legs together, turn the woman on her side and let her go. The result is the perineum fills up more or less with granulations, followed by the usual amount of cicatricial tissue. If, however, a suitable suture had been used at the time, and union obtained by first intention, as may usually be done, then the many secondary results of a lost perineum will be saved the woman in the future. By sewing up the parts at once, the danger of septicaemia from absorption of the lochial discharges running over the abraded surfaces is prevented. But in many cases, when the operation is done at the right time, nothing is gained because of the sutures being inadequate for the work for which they are intended. As the selection of a proper suture has a great deal to do with getting a good result from the operation, and as it has been repeatedly shown by abundant experience that the principal difficulty with sutures has been, that they either dissolve too readily before union is perfected, or else give rise to troublesome ulceration; then, what is wanted is a suture which combines in itself both strength and non-irritability.

The sutures which have been most commonly used are the carbolyzed cat-gut, silk, silver wire, silver plated and nickel plated iron wire, annealed iron wire (which is used considerably in France), and, for a great many years by Dr. H. H. Hill, of Augusta, Maine, the lead wire. I do not know of this latter having been used by others than Dr. Hill, who has kindly told me of its advantages. Besides those above mentioned, horse-hair and split tendon have been used to a slight extent.

Carbolyzed cat gut has been probably used for the past few years in the primary operation more frequently than any other material. The disadvantage in the use of this is easily seen, from its too readily dissolving and allowing, in most cases, the parts to separate on the third or fourth day, when the cat-gut gives out, before the torn surfaces are even partially united.

Silk has been, and is, used a great deal, but it irritates and produces ulceration, necessitating removal before thorough and complete union is obtained.

Silver wire works very well, but is quite expensive. I saw it used a great deal in Vienna the past winter by Dr. Powlik, in Professor Braun's wards. Besides expense the principal fault found with it was, that it caused some ulceration before the parts were firmly united.

Silver-plated and nickel-plated iron wire answer admirably as regards strength, but the trouble is the plating wears off too soon, often coming away in flakes, leaving the exposed iron, which soon makes trouble.

Annealed iron wire has been used, but it does not answer all purposes. If the iron wire is polished it works better, but the expense is considerably increased.

Tendon has been so little used that not much is known about it. One complaint about its preparation has been the difficulty of splitting the tendon into threads.

Gut and horse hair have been considered the least irritating materials for sutures we possess.

Bryant says iron and silver sutures are about as irritating as silk, but not more so.

Regarding lead wire, which has been but little used, I shall say more than of the others, as it seems well worth being tried where there is the necessity for a

metallic suture, not only in operations on the perinaeum, but also in other surgical operations, especially when mucous surfaces are involved. I refer to it in this article, however, only in its connection with the perinaeum.

I have had but one opportunity to use the lead wire myself, but in that case it worked splendidly in every way.

Dr. Hill informed me that he has used the lead wire for more than twenty-five years in his practice, with excellent results: never seeing the slightest ulceration from its use, and in no case was it necessary to remove the wire till a cure was obtained.

The lead wire can be prepared by any one, by cutting off strips about one eighth of an inch wide, from a piece of sheet lead, and then drawing it through a wire-plate, to any size needed. The usual size required to possess the requisite amount of strength is about as large as the ordinary pocket-case probe, about half an inch from its bulbous end. Soft soap is a very good vehicle to rub on the wire, as it is being drawn down.

The only sutures we have then, which can be used to advantage, are the silver and lead. The trouble with the former is its expense and a certain amount of ulceration which it will produce. The lead wire answers every purpose. It is sufficiently strong for use anywhere, where metallic sutures are wanted. It does not produce ulceration, is pliable and inexpensive, and can be easily made by any one. It can be left in as long as desirable, till the parts are fully united, without causing any trouble whatever.

If the lead wire should be used more frequently in the primary operation I think there would be far fewer cases presenting themselves for a secondary operation.

Dr. W. L. Richardson, in a recent article, says: "Perineal sutures should be put near together, and not drawn too tightly." The nearness of the sutures prevents interspaces to be filled up by granulations, and by not drawing the sutures too tightly strangulation of the vessels is prevented.

During my term of service as interne, at the Boston Lying-In Hospital, under Dr. Richardson, it was shown on a number of patients, that if the woman's legs were drawn apart much farther than they would naturally be by her own unintentional movements, the perinaeum was not drawn upon at all. If the legs, or especially one leg, should be flexed at a right angle with the body or drawn up still nearer the abdomen, then the perinaeum was drawn upon, varying in extent with the amount of flexion.

Boston, October 10, 1881.

MALARIAL DISORDERS IN NEW ENGLAND.

THE secretary of the Connecticut State Board of Health, in his September report, says, in regard to malarial disorders, that "New Haven shows the greatest mortality from malarial diseases this month, — twelve in all. The protracted drought doubtless has been an efficient factor in causing the increased prevalence of malarial diseases reported, pretty generally where these diseases have become more or less established. The greatest increase yet mentioned is at Thompsonville, where nearly a hundred cases occurred almost simultaneously. The mortality in Hartford does not show increase, but more cases are reported. There is no exemption from age. Even infants are attacked in

many places. The attendance at school is more or less interfered with by the recurring chills. Fairfield, where considerable attention to drainage has been paid, reports a few cases through the drought, but much less than in former years, while for the present, New Milford, where similar work in systematic drainage has been done, is reported as entirely free from malarial diseases for the present at least.

"Quite an outbreak is reported in the northern part of Providence, R. I., and in Cranston and Elmwood, adjacent villages. A hundred cases or more are estimated in Providence city limits. As we have it endemic in New York and the valley of the Hudson and thus far in the Housatonic, Naugatuck, Quinnipiac, Farmington, and Connecticut River valleys, and to the northward as far as Holyoke at least, the prospects for a complete invasion of the State are very good. Thus far the greater portion of New London, Tolland, and Windham counties have escaped, and some portions of Litchfield County have been but lightly invaded. In Massachusetts reports occasionally come to hand of the encroachments east and west from the Connecticut River valley."

PREVENTIVE MEDICINE AND EXPERIMENTAL PHYSIOLOGY.¹

THE experiments which give us our teaching with regard to the causes of disease are of two sorts: on the one hand we have the carefully prearranged and comparatively few experiments which are done by us in our pathological laboratories, and for the most part on other animals than man; on the other hand we have the experiments which accident does for us, and, above all, the incalculably large amount of crude experiment which is popularly done by man on man under our present ordinary conditions of social life, and which gives us its results for our interpretation. . . .

Let me illustrate my argument by showing you the two processes at work in identical provinces of subject-matter. What are the classical experiments to which we habitually refer when we think of guarding against the dangers of Asiatic cholera? On the one side there are the well-known *scientific* infection experiments of Professor Thiersch, and others following him, performed on a certain number of mice. On the other hand there are the equally well-known *popular* experiments which, during our two cholera epidemics of 1848-49 and 1853-54, were performed on half a million of human beings, dwelling in the southern districts of London, by certain commercial companies which supplied those districts with water. Both the professor and the companies gave us valuable experimental teaching as to the manner in which cholera is spread. I need not state at length the facts of those experiments, probably known to all here, but may rather justify my parallel by referring to an aetiological question which will presently be discussed in our section. . . .

The two sorts of experiment — the scientific and the popular — differ, as I have noted, in this particular: that the popular experiment is almost always done on man, the scientific almost always on some other animal. It is true that many memorable cases are on record

¹ Extracts from an Address on State Medicine, delivered at the opening of the Section of Public Medicine in the International Medical Congress, by John Simon, C. B., F. R. S., D. C. L., LL. D.

where members of our profession have deliberately given up their own persons to be experimented on by themselves or others for the better settlement of some question as to a process of disease; have deliberately tried, for instance, whether, in this way or in that, they could infect themselves with the poison of plague or of cholera; and as regards one such case which is in my mind, I think it not unlikely that the illustrious life of John Hunter was shortened by the experiments which he did on himself with the ignoble poison of syphilis. There have been cases, too, where criminals have been allowed to purchase exemption from capital or other punishment at the cost of allowing some painful or dangerous experiment to be performed on themselves. And cases are not absolutely unknown where unconsenting human beings have been subjected to that sort of experiment. But waiving such exceptions, the rule is, as I have said, that scientific experiments relating to causes of disease are performed on some animal which common opinion estimates as of lower importance than man. Now, as between man and brute, I would not wish to draw any distinction which persons outside this room might find invidious, but, assuming for the moment that man and brute are of exactly equal value, I would submit that, when the life of either man or brute is to be made merely instrumental to the establishment of a scientific truth, the use of the life should be economical. Let me, in that point of view, invite you to compare, or rather to contrast with one another, those two sorts of experiment from which we have to get our knowledge of the causes of disease. The commercial experiments which illustrated the dangerousness of sewage-polluted water supplies cost many thousands of human lives; the scientific experiments which with infinitely more exactitude justified a presumption of dangerousness, cost the lives of a few dozen mice. So, again, with experiments as to the causation of tubercle; judging from the information which I quoted to you, I should suppose that the human beings whose milk supply on any given day includes milk from tubercular cows might be counted, in this country, in tens of thousands; but the scientific experiments which justify us in declaring such milk supply to be highly dangerous to those who receive it were conclusive when they amounted to half a dozen. So far, then, as regards the mere getting of experimental knowledge, we must not, with a view to economy of life, be referred to popular, rather than scientific, experiment. And in the same point of view it perhaps also deserves consideration that the popular experiments, though done on so large a scale, very often have in them sources of ambiguity which lessen their usefulness for teaching.

Let me now briefly refer to the fact that, during the last quarter of a century, all practical medicine (curative as well as preventive) has been undergoing a process of transfiguration under the influence of laboratory experiments on living things. The progress which has been made from conditions of vagueness to conditions of exactitude has, in many respects, been greater in these twenty-five years than in the twenty-five centuries which preceded them; and with this increase of insight, due almost entirely to scientific experiment, the practical resources of our art, for present and future good to the world, have had, or will have, commensurate increase. Especially in those parts of pathology which make the foundation of preventive medicine, scientific experiment in these years has been

opening larger and larger vistas of hope; and more and more clearly, as year succeeds year, we see that the time in which we are is fuller of practical promise than any of the ages which have preceded it. Of course I cannot illustrate this at length, but some little attempt at illustration I would fain make. First, let us glance at our map. When we generalize very broadly the various causes of death (so far as hitherto intelligible to us) we see them as under two great heads, respectively autopathic and exopathic. On the one hand there is the original and inherited condition under which to every man born there is normally assigned eventual old age and death, so that, sooner or later, he "runs down" like the wound-up watch with its ended chain; and, as morbidities under this type, there are those various original peculiarities of constitution which make certain individual tenures of life shorter than the average, and kill by way of premature old age of the entire body, or (more generally) by quasi-senile failure of particular organs. On the other hand, as a second great mass of death-causing influence, we see the various interferences which come from outside; acts of mechanical violence, for instance, and all the many varieties of external morbid influence which can prevent the individual life from completing its normal course. As regards cases of the first class — cases where the original conditions of life and development are such as to involve premature death (which in any such case will commonly show itself as a fault in particular lines of hereditary succession) — the problem for preventive medicine to solve is, by what cross-breeding or other treatment we may convert a short-lived and morbid into a long-lived and healthy stock; and this, at least as regards the human race, has, I regret to say, hardly yet become a practical question. But as regards cases of the second class, evidently the various extrinsic interferences which shorten life have to be avoided or resisted, each according to its kind; and here it is that the scientific experimenters of late years have been giving us almost daily increments of knowledge. . . .

I have reason to believe that if that Act (the Contagious Diseases Act) continues on the statute-book one of two results will follow. Experiments, indispensably necessary for the growth of medical science in relation to the cure and prevention of disease, will cease, or almost cease, to be done in this country; or, as the alternative to this, persons who desire to advance the science of their profession, will be tempted to clandestinely ignore the law and to run their chance, if the worst comes to the worst, of having to try conclusions with the common informer.

Let me illustrate this by two personal references; I have already mentioned Professor Lister as an experimenter, whose name is now classical wherever science has reached, and whose work has been of signal advantage to mankind. Last autumn Mr. Lister wished to do some experiments in extension of the particular branch of knowledge with which his name is identified, and at a point which he considered of extreme importance in surgical pathology. He found he must either abandon his investigation or must conduct it in a foreign country, and in his zeal for science he chose the latter course. His experiments (which had to be on large animals) were done at the Veterinary College of Toulouse; and in stating this fact in a letter, from which I quote, Mr. Lister added that "even with reference to small animals, the working of the Act is

so vexatious as to be practically prohibitory of experiments by a private practitioner like myself, unless he chooses to incur the risk of transgressing the law." A second name which I have mentioned is that of Professor Greenfield, who has so highly distinguished himself in developing, by means of experiments, the preventive medicine of splenic fever. Dr. Greenfield, in order to perform his inoculation experiments, had of course to become a license-holder under the Act; and his experience of the hindrances which attach to that position is expressed to me in the following terms: "It is my deliberate conviction, as a result of my experience, that these hindrances and obstacles are so numerous and so great as to constitute a most serious bar to the investigation of disease, and even of such remedial measures as would by common consent be for the direct benefit of the animals experimented upon. When to this is added all the annoyance and opprobrium which are the lot of investigators, it is to be wondered at that any one should submit to be licensed." Dr. Greenfield's experimental operations consisted only in inoculating the virus of animal diseases, and he says: "I have not been engaged in other investigations for the simple reason that, with the present restrictions and the difficulty of obtaining a license, I regard it as almost hopeless to attempt any useful work of the kind in this country."

As I feel sure that the Act must at no distant time be reconsidered by the Legislature, and as I also very strongly feel that, quite apart from any question of legal enactments, there is the question of moral right or wrong to be considered in the matter, I would beg you to allow me to make my own public confession of faith (from which I dare say yours will not much differ) in that extremely important matter of controversy.

[In connection with the preceding, we take the following parenthetical remarks from a clinical lecture of Dr. William Hunt's, appearing in the *Medical News and Abstract*. — Ed.]

"This was the case that thus early in my surgical life strongly impressed me with the phenomena that occur in serious injuries to the spinal column and cord, or to either of them. In those phenomena I have ever since taken a deep, though melancholy, scientific interest; melancholy, because of the utter hopelessness of recovery for most of the victims; scientific, because these and brain cases are those which give us more knowledge of the physiology of the nervous system than anything else.

"They are cruel, accident vivisections, vivisections performed on the highest of God's creatures. I dislike vivisection, although I have done something at it in my day; but I have frequently thought when standing helpless at the bedside of one of these terrible cases of spinal injury, that if a dog could be wounded and give me any light for the relief of the man, it ought to be done. I think of Him who said, 'Ye are of more value than many sparrows,' and I say ye are of more value than a few dogs."

THE STANDARD OF COWS' MILK.

An interesting paper has been published by Professor C. A. Cameron, in a recent number of the *Scientific Proceedings of the Royal Dublin Society*, on the composition of the milk of cows. During the winter quarter of 1880, analyses were made of the milk of

forty-two cows which were kept at the government agricultural institution, known as the Albert Farm, at Glasnevin, in the county of Dublin. The morning's and the evening's milk of each cow were each analysed once, and an examination of the mixed milk of the forty-two cows was also made on the 11th of December, 1880. The cows were, as might be expected, good animals, having from one to three crosses of the Shorthorn breed. They were in the house during the period of the experiments; their food consisted of a daily allowance of about nine stone of pulped mangolds and turnips with exhausted brewery grains, together with about one stone of hay. Their ages ranged from four to nine years inclusive. Dividing them into two groups — those aged four and five years, and those aged eight and nine years — a marked difference in favor of the milk of the latter, both in quantity and quality, was noticed. This, however, might easily be accounted for by the process of artificial selection, for while it is only good milch cows that would be kept in the dairy for several years, the younger ones, proved not to be good milkers, would be put into the fattening stalls. The belief that milk becomes deteriorated in quality towards the end of lactation was not supported by these experiments. The quantity naturally became scanty, but the quality improved. The average yield of milk was for each cow $11\frac{1}{4}$ quarts. In every instance, the quantity of milk yielded in the morning exceeded the proportion furnished in the evening, eight hours intervening between the milkings. Thirty out of the forty-two cows gave richer milk in the evening than in the morning; eleven gave richer milk in the morning than in the evening, while the remaining cows' milk was equally good at both milkings. The increase in the amount of solid matters in the evening's milk was chiefly due to the larger amount of fats contained in the latter. — *Sanitary Record*.

BOSTON MEDICAL LIBRARY ASSOCIATION.

AN APPEAL TO THE PROFESSION AND TO THE PUBLIC.

THREE years ago the Boston Medical Library Association appealed to the profession and public for pecuniary aid to enable it to purchase and fit up a house to contain its extensive library, and also a hall for the meeting of all the medical associations in the city. More than ten thousand dollars were then subscribed, the building bought and altered, leaving the Association with a mortgage of eight thousand dollars and a floating debt of four thousand dollars; the latter has since been reduced to one thousand dollars, by further subscriptions by the profession and by the practice of the most rigid economy.

The usefulness of the Institution has been so fully appreciated and endorsed by the profession, and the Directory for Nurses, established and carried on by the Association, has proved such a boon to physicians, nurses, and especially the public, that the executive committee feel authorized to appeal for a new subscription of fifteen thousand dollars for the purpose of cancelling the entire debt, making some pressing and long-neglected alterations and repairs, and having a small fund for binding and for buying new books, as soon as issued.

With this sum we feel that the Library Association will be established on so lasting a basis as to preclude

the necessity of appeals for pecuniary assistance in the future.

It is not necessary to dwell upon the value of libraries in general, but we would remind our patrons that the mass of medical literature is now so great as to be beyond the purchasing power of even the richest physicians, and yet the life and health of every individual in the community, is, in a large measure, dependent upon a familiarity, on the part of the medical profession, with every advance in the science and practice of medicine.

To meet this pressing need more fully than has heretofore been possible with our limited resources, we hereby appeal to the profession and the public.

Subscriptions may be sent to any of the undersigned.

O. W. HOLMES,	W. L. RICHARDSON,
F. I. KNIGHT,	EDW. WIGGLESWORTH,
O. F. WADSWORTH,	P. C. SHATTUCK,
CHARLES P. PUTNAM.	

Executive Committee.

19 BOYLSTON PLACE, BOSTON, October, 1881.

CONGRESS CORRESPONDENTS.

The *British Medical Journal* says editorially:—

"A Journal-Reader" writes to us: Most of the correspondents who have reported their notes on the recent Congress have done so in language of warm compliment and congratulation. Some of the French correspondents are a little dissatisfied that their own language was not more generally spoken, and that they could not understand any other. One or two of them complain that there were too many Germans; and one, that the Germans ate too much, and carried their wives' portraits about with them in lockets. The Germans are generally well pleased. The *Berliner Klinischer Wochenschrift* observes that the public and opening addresses were, with the exception of Pasteur's, somewhat unsubstantial. The American journals, especially the *New York Medical Record* and the *Boston Medical Journal*, give excellent reports of the proceedings; so does the *Progrès Médical* in France. Some of the reporters are easily censorious; very few carefully criticised. Dr. Rumbold has made quite a little collection of things which ought not to be, and of tales out of school, with which he regales his countrymen. At the Liverpool Infirmary, he was scandalized with the "young ward doctors;" "the most of them," he observes parenthetically, "part their hair in the middle." He spoke to the young gentleman who thus incurred his wrath, of the nasal cavities and Eustachian tube, and reports this answer: "Oh, that is a nasty part of the head; we can learn enough of this in the books." "His contempt, his conceit, and his ignorance," says the amiable visitor, "were equal." Dr. Rumbold was then taken through the whole hospital. His comment is: "As I have said, I saw nothing that was striking, except the universal clumsiness of their splints for fractures of all kinds." Except for grammar and orthography, this leaves nothing to be desired. Coming on to London, he has much to say of the bungling mistakes of brilliant operators. Thus he describes an operation in which the mastoid process was needlessly trephined and the lateral sinuses opened. He adds: "I am very certain that it will pay American physi-

cians to come over here and see mistakes made; but to see them too often makes one too reckless, which is closely allied to barbarism." He adds: "As an instance of heroic surgery at one of the old hospitals, I may direct the reader's attention to an operation of ovariectomy performed there. The abdomen was ripped from pubis to sternum, and what appeared to me to be ovarian or ovario-uterine or uterine fibroid, by a persistent and persevering series of separating, tearing, ligating, and dividing, was taken out of the then apparently (at a casual look) eviscerated subject, and the extensive wound stitched up, just before the patient breathed her last." Further: "A gynaecologist of considerable experience a few days ago proposed to do ovariectomy; but, after opening the abdomen, he found the tumor to be uterine, when he declined to proceed further, and closed up the opening at once. Another prominent gentleman found a tumor in the upper portion of the vagina displacing the uterus somewhat; but it was found by a more careful diagnostician that the woman had pelvic cellulitis." Partly, however, our censorious friend relents. "Notwithstanding, in some instances, John Bull, with self-complacent dignity and a sullen icicle selfishness apparent, passes his American cousin, and even his European *confères*; yet many London doctors show the true gentlemen that they are and seem willing and anxious to interest and entertain strangers from every land; and I shall return to America glad that I came, and with many pleasant recollections connected closely with medical men of the great city of London." This will save some of us from being too much elated at the success of our efforts to entertain our visitors and show them what was best worth seeing. It may also interest our instrument-makers and more inventive surgeons, to know that M. Fochier of Lyons is of opinion that there was nothing new in the display of instruments, and that French models were largely copied and exhibited as English novelties.

DRAINAGE OF THE PERICARDIUM.

A CASE, probably unique in the annals of paracentesis, has been recorded by Rosenstein, of Leyden. A child, aged ten years, suffering from pericardial effusion, presented such a degree of interference with circulation and respiration, that an aspirator needle was passed into the fourth intercostal space, near the sternum, and 620 cubic centimetres of liquid were withdrawn. Left-sided pleural effusion soon followed, and 1100 cubic centimetres of liquid were evacuated. The cardiac symptoms increased, and necessitated a second puncture of the pericardium; 120 cubic centimetres of purulent liquid were withdrawn. A relapse occurring, a larger opening was made (an inch and a half long) in the fourth intercostal space. The soft parts were divided layer by layer under strict antiseptic precautions. When the pericardial cavity was reached a large quantity of pus escaped. Two drainage tubes were inserted. The operation was followed by an immediate return of the circulation and respiration to normal conditions. An incision into the pleura, however, also became necessary. At the end of four months of treatment the patient left the hospital in good condition. There was no pyrexia or oedema of the skin in the precordial region to indicate the purulent nature of the effusion. — *The Lancet*.

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 29, 1881.

Cities.	Population by Census of 1880.	Reported Deaths in each.	Deaths under Five Years.	The Principal "Zymotic" Diseases.	Percentage of Deaths from

Deaths reported 2734 (no report from St. Louis): 1053 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 860, consumption 412, diphtheria and croup 286, lung diseases 228, diarrhoeal diseases 169, typhoid fever 124, small-pox 89, scarlet fever 74, malarial fevers 60, whooping-cough 20, cerebro-spinal meningitis 19, puerperal fever 11, erysipelas four, measles three, typhus fever one. From *small-pox*, Chicago 49, Pittsburgh 21, New York seven, Philadelphia six, Boston and Cincinnati three. From *scarlet fever*, New York 31, Brooklyn 14, Philadelphia 10, Pittsburgh five, Baltimore and Buffalo three, Chicago and Milwaukee two, District of Columbia, Worcester, Fall River, and Fitchburg one. From *malarial fevers*, Brooklyn 17, New York 12, District of Columbia nine, New Orleans five, New Haven four, Baltimore and Nashville three, Chicago two, Philadelphia, Pittsburgh, Charleston, Lynn, and Holyoke one. From *whooping-cough*, New York 10, Chicago three, Baltimore two, Philadelphia, Brooklyn, District of Columbia, Cambridge, and Salem one. From *cerebro-spinal meningitis*, New York six, Chicago and Buffalo two, Philadelphia, Cincinnati, District of Columbia, Milwaukee, Fall River, Lynn, Springfield, New Bedford, and Chelsea one. From *puerperal fever*, Chicago and Milwaukee two, New York, Boston, Baltimore, New Orleans, Buffalo, Lynn, and Holyoke one. From *erysipelas*, New York two, Chicago and Boston one. From *measles*, Chicago, Cincinnati, and Providence one. From *typhus fever*, New York one.

Eighteen cases of small-pox were reported in Brooklyn, nine in Boston, 11 in Cincinnati, 89 in Pittsburgh, one in Buffalo; diphtheria 39, scarlet fever nine, typhoid fever 40, in Boston; diphtheria eight, scarlet fever eight in Milwaukee.

In 41 cities and towns of Massachusetts, with a population of

1,067,299 (population of the State 1,783,086), the total death-rate for the week was 19.64 against 21.29 and 23.50 for the previous two weeks.

For the week ending October 8th in 149 German cities and towns, with an estimated population of 7,936,736, the death-rate was 23.3. Deaths reported 3560; under five 1688: pulmonary consumption 434, acute diseases of the respiratory organs 237, diarrhoeal diseases 193, diphtheria and croup 163, scarlet fever 121, typhoid fever 72, whooping-cough 64, puerperal fever 22, measles and *rötheln* nine, small-pox (Aachen) three, typhus fever (Rostock, Thorn two) three. The death-rates ranged from 14.3 in Lubek to 36.2 in Görlitz; Königsberg 25.1; Breslau 26.9; Munich 30.5; Dresden 25.7; Berlin 25; Leipzig 16.5; Hamburg 21.4; Hanover 16.1; Bremen 16.9; Cologne 19; Frankfurt 15.6; Strassburg 20.

For the week ending October 15th in the 20 English cities with estimated populations of 7,608,775, the death-rate was 20.5. Deaths reported 2985; acute diseases of the respiratory organs (London) 279, scarlet fever 170, diarrhoea 85, measles 70, fever 63, whooping-cough 61, diphtheria 29, small-pox (London 22) 23. The death-rates ranged from 14.8 in Leicester to 27.9 in Liverpool; Bristol 15.1; Leeds 17.1; Sheffield 17.2; London 19.9; Manchester 21.9; Birmingham 22.6. In Edinburgh 21.4; Glasgow 23.3; Dublin 18.2.

For the week ending October 15th in the 21 chief towns of Switzerland, population 479,934, there were 25 deaths from diarrhoeal diseases; acute diseases of respiratory organs 16, scarlet fever four, diphtheria and croup two, typhoid fever two, puerperal fever one. The death-rates were, Geneva 22; Zurich 22.3; Basle 19.3; Berne 21.1.

The meteorological record for the week ending October 29th, in Boston, was as follows:—

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM OCTOBER 29, 1881, TO NOVEMBER 4, 1881.

DAVIS, W. B., first lieutenant and assistant surgeon. Relieved from duty in Department of Dakota, to proceed to Richmond, Va., and, on arrival, report by letter to the Surgeon-General. S. O. 240, C. S., A. G. O.

KOLMER, E. A., captain and assistant surgeon. Relieved from further duty at Yorktown, Va., and to proceed to Plattsburg Barracks, N. Y. S. O. 191, Department of the East, November 3, 1881.

CARVALLO, C., captain and assistant surgeon. Granted leave of absence for one month on surgeon's certificate of disability, with permission to go beyond the limits of the department and to apply for five months' extension. S. O. 108, Department of the Platte, October 24, 1881.

SKINNER, J. O., captain and assistant surgeon. Relieved from duty as acting medical purveyor in the field, and to proceed to his proper station, Whipple Barracks, A. T. S. O. 123, Department of Arizona, October 26, 1881.

ARTHUR, WILLIAM H., first lieutenant and assistant surgeon. Relieved from duty at Fort Sanders and assigned to duty at Fort Washakie, Wyo. Ter. S. O. 110, Department of the Platte, October 29, 1881.

APPOINTMENTS. — To be assistant surgeons, with the rank of first lieutenant: —

EDWARD C. CARRER, of New York, October 22, 1881, *vice* Phillips, deceased.

HENRY I. RAYMOND, of New York, October 22, 1881, *vice* O'is, promoted.

THOMAS J. C. MADDOX, of New York, October 22, 1881, *vice* Smith, resigned.

RICHARD W. JOHNSON, of Minnesota, October 22, 1881, *vice* Jaquett, promoted.

G. O. 77, A. G. O., October 31, 1881.

ERRATUM. — In the report of the American Academy of Dental Science, November 3d, page 134, Dr. T. L. Williams should read Dr. J. L. Williams.

BOOKS AND PAMPHLETS RECEIVED. — A Manual for Hospital Nurses and others engaged in attending on the Sick. By Edward J. Danville, L. R. C. P. Lond. Fourth Edition. Philadelphia: Presley Blakiston. 1881.

Second Annual Report of the State Board of Health, Lunacy, and Charity of Massachusetts. 1880. Supplement containing the Report and Papers on Public Health.

Third Annual Report to the Legislature of Massachusetts regarding the Registry and Return of Births, Marriages, and Deaths in the Commonwealth for the Year ending December 31, 1880.

A Practical Treatise on Hernia. By Joseph H. Warren, M. D. Second and Revised Edition. Fully Illustrated. Boston:

James R. Osgood and Company. London: Sampson, Low, Marston, and Rivington. 1882. All rights of translation reserved by the author.

Artificial Anesthesia and Anesthetics. By Henry M. Lyman, M. D. New York: William Wood & Co. 1881. Library of Standard Medical Authors.

A Treatise on Orthopaedic Surgery. By J. Warrington Howard, F. R. C. S. London: Longmans, Green & Co. 1881.

New System of Ventilation, which has been thoroughly tested under the Patronage of many Distinguished Persons, being adapted to Parlors, Dining and Sleeping Rooms, Kitchens, Basements, Cellars, Vaults, Water-Closets, etc., etc. A Book for the Household. Fourth Edition, enlarged, with New Illustrations. By Henry A. Gouge. New York: D. Van Nostrand. 1881.

Favorite Prescriptions of Distinguished Practitioners, with Notes on Treatment. By B. W. Palmer, A. M., M. D. New York: Birmingham & Co. 1881.

Essentials of the Principles and Practice of Medicine. A Handbook for Students and Practitioners. By Henry Hartsborne, A. M., M. D. Fifth Edition. Thoroughly revised and improved, with one hundred and forty-four illustrations. Philadelphia: Henry C. Lea's Son & Co. 1881.

Chronic Pelvic Abscess. A Contribution to the Differential Diagnosis of Abdominal Tumors. By A. F. Erich, M. D., Professor of Diseases of Women, College of Physicians and Surgeons, Baltimore. (Pamphlet.)

Ophthalmology, Ancient and Modern. Annual Address before the Maine Medical Association, June 22, 1881. By James A. Spaulding, M. D. Portland: Stephen Berry, Printer. 1881.

Historical Sketch of the Obstetrical Society of Boston. By Benjamin E. Cotting, M. D. (Harv.) Boston: David Clapp & Son. 1881.

Three Cases of Compound Committent Fracture of the Leg. Recovery without Suppuration. By Thomas R. Wright, M. D. (Reprint.)

The Science and Art of Midwifery. By William Thompson Lusk, A. M., M. D. With numerous illustrations. New York: D. Appleton and Company. 1882.

A Treatise on the Diseases of Infancy and Childhood. By J. Lewis Smith, M. D. Fifth Edition, thoroughly revised, with illustrations. Philadelphia: Henry C. Lea's Son & Co. 1881.

A Text-Book of Physiology. By M. Foster, M. A., M. D., F. R. S. Second American from the Third and Revised English Edition. With Extensive Notes and Additions. By Edward T. Reichert, M. D. With two hundred and fifty-nine illustrations. Philadelphia: Henry C. Lea's Son & Co. 1881. (A. Williams & Co.)

The Therapeutics of Gynecology and Obstetrics, comprising the Medical, Dietetic, and Hygienic Treatment of Diseases of Women. Second Edition, thoroughly revised and greatly enlarged. Edited by William B. Atkinson, A. M., M. D. Philadelphia: D. G. Brinton. 1881.

Historical Sketch of the Medical Societies of Baltimore, Md., from 1730 to 1880. By G. Lane Tameyhill, A. B., M. D.

State Medicine. An Address delivered before the New Hampshire Medical Society. By G. P. Conn, M. D. (Reprint.)

Photographic Illustrations of Cutaneous Syphilis. By George Henry Fox, M. D. Parts X, XI, XII.

Lectures.

CLINICAL LECTURE ON DISEASES OF WOMEN.¹

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

BY PROF. T. GAILLARD THOMAS, M. D.

CASE I. FIBROID OF THE OVARY.

GENTLEMEN, — Before introducing any new patients to-day, I wish to say a word in regard to the one whom you saw here three weeks ago, and whom some of you saw me operate on a fortnight since at the Woman's Hospital. Since my last report of the case to you the sutures have been taken out, and the woman has continued to do perfectly well in every respect. As to the character of the tumor removed I have a correction to make. When I exhibited it to you last week I told you that it was a sarcoma of the ovary, which is a kind of malignant growth liable to return, and which would render the ultimate prognosis very unfavorable. At that time it had been examined only by an inexperienced microscopist; but since then it has been placed in the hands of Prof. Francis Delafield, and he has written me concerning it as follows: "The outer portions of the solid ovarian tumor removed by you are composed of dense, compact tissue; the central portions of a looser and more spongy tissue. The anatomy of both these portions, however, is essentially the same. Their structure resembles that of the ordinary fibroid tumors of the uterus. That is, they are composed of connective tissue and smooth muscular fibres. The tumor is, therefore, a *myo-fibroma*. There has been, as you know, some question whether ovarian tumors ever contain smooth muscle; but the best authorities now admit that it does sometimes exist in such tumors. I suppose that you are certain that this tumor was not attached to the uterus, nor contained in one of the broad ligaments."

[Before the removal of the tumor it was supposed by Dr. Thomas to be an ordinary case of uterine fibroid with long pedicle. His reasons for undertaking the operation were that the growth had given rise to abdominal dropsy and was rapidly undermining the health of the patient. P. B. P.]

The question which Dr. Delafield suggests is a very natural one in view of the extreme rarity of ovarian fibroids; but I could not possibly have been mistaken in regard to the attachment of the tumor for the reason that when I was performing the operation I took the precaution of lifting both the uterus and ovaries outside of the body in order to be sure about the matter. It was without doubt a fibroid of the ovary with a long pedicle, and was the first one of the kind that I have met with in all my experience. I was mistaken, therefore, in my diagnosis previous to the operation only as regards the attachment of the tumor, and such a mistake is certainly excusable when the fact is considered that there is no means whatever known to science for determining absolutely in such a case whether the growth is attached to one of the ovaries or to the uterus. I reasoned in this way: It must belong either to the uterus or to one of the ovaries, and as fibroids of the uterus are exceedingly common, while those of

the ovaries are so exceedingly rare as almost never to be met with, it was in all probability connected with the former.

CASE II. RUPTURE OF THE PERINEUM FOLLOWED BY PROLAPSE UTERI.

Ann R., aged forty years and a native of Ireland. She has had one child (six years ago) but no miscarriages, and is now a widow.

How long have you been complaining? "For about a year." How do you suffer? "From a great pain in my back." What else? "Pains in my knees, legs, and shoulders." Do you suffer much at your monthly periods? "No." Can you walk about pretty well? "Yes." Can you go up and down stairs well? "No." Can you do as much work as before you began to feel badly? "Oh, no." Have you any trouble about your bladder? "I have to pass my water too often." How many times during the night? "Only once or twice at night, but I have to pass it very often indeed through the day." You feel relieved in this respect, then, at night? "Yes." Do you have the whites? "Yes."

You observe that the patient has a very strong frame, such as we commonly associate with persons in robust health; but it needs only a glance to see that she looks harassed and depressed. As you have heard, she was well up to one year ago, when she began to suffer from great weakness and pain in the back and thighs. Then followed leucorrhœa and irritability. Such symptoms scarcely seem like those that could seriously affect a patient apparently so strong, and she herself does not make very much of them; but yet the fact remains that she cannot do her ordinary work any more.

Now let me show you what took place in this woman's case six years ago, and has really caused all her trouble, although she has been complaining only for the past year. Before the birth of her child her uterus was kept up in place by the ordinary means provided by nature for the support of this organ; but at the time of the delivery the perineal body was split directly in two, the rupture of the parts extending completely back to the anus. What was the result of this accident? Presently the bladder began to fall, because the laceration of the perineum took away its entire support; and as it descended lower and lower, the uterus (which was in a state of subinvolution and greatly enlarged) came down with it. The patient's system bore up nobly under such a strain; but at last, at the end of five long years, it began to give out. The uterus has not as yet come down outside of the body in this case, but it has fallen down to the vulva; so that the fundus thus presses upon the bladder, while the rectum, on the other hand, is dragged upon.

Next we inquire, Can the symptoms, of which the patient complains, be satisfactorily explained by such a prolapsus uteri as we find here? and the answer is, "Undoubtedly they may." This is in some respects a prolapsus of the second degree: but it is to be classed as one of the first degree, because, for some reason, the uterus still retains its normal axis, instead of having become retroverted, as is generally the case. I presume that if nothing were done to prevent it the organ would, before a great while, come down entirely outside of the body; the ligaments having finally given up all resistance.

I wish to pause here for a moment to say, that any

¹ Reported by P. Brynberg Porter, M. D.

medical man who is in the habit of practicing obstetrics and ignores such an accident as rupture of the perineum had better, by all means, give up this branch of the profession. All sorts of uterine troubles are constantly arising from it; and the most lamentable part of the matter is that they might all have been avoided if the accoucheur in attendance in each case had only performed his duty properly. Of course, rupture of the perineum is sometimes inevitable, in spite of all our efforts to save it; but not infrequently the accident can be prevented by a little care. For instance, when forceps are employed it is better to take them off before the head is delivered. If by taking every precaution, then, we can prevent the perineum from giving way, we are doing a vast deal for the patient's present safety, as well as for her future welfare. There are some who boast that they do not even tear the fourchette in delivering their patient; but as a fact it is found that this almost invariably gives way. Such a rupture, however, is physiological, rather than pathological, and it is not of this that I am speaking. More extensive lacerations of the perineum are, unfortunately, very frequent, and, indeed, they take place in the great majority of instrumental labors. Of course, I do not mean that in the generality of forceps cases the perineum is torn all the way through to the anus; but enough injury is done to give rise to very serious trouble. When we consider what an acrid and irritating fluid the lochial discharge is, it certainly appears marvelous that more parturient women do not die of septicæmia, because when there is a rupture of the perineum the raw surfaces are constantly bathed by this irritating material pouring from the uterus. Yet this is only one of the many evils that result from this accident.

Now suppose that, in some case, in spite of all efforts to prevent it, you find that there has been a rupture of the perineum. The question at once presents itself, Shall I close it or shall I let it alone? While it is impossible to lay down any law that shall be universally applicable in such cases, the rule is, put in sutures immediately and repair, as far as it is possible, the damage that has been done. To this, however, there are some exceptions. When, for instance, the patient has lost a large quantity of blood, or has otherwise become much exhausted during labor, or when there are weak-minded relatives present who will cry out with horror at the mere thought of such a procedure, and nearly frighten the patient to death, it is better to delay the operation until a more appropriate time. If the patient has been bleeding very profusely, she may actually die while the sutures are being put in, and, of course, any obstetrician who attempts to operate under such circumstances must be regarded as culpable.

If done carefully and thoroughly the immediate operation is generally successful. Usually, however, the practitioner does not have the necessary appliances for operating with him, but it should be the rule of every one who practices obstetrics at all to always have the things required at hand in every case which he attends. When this is the fact he can put in the sutures without any delay, and if anesthetics have been previously used during the labor, the patient very often is entirely unaware that any operation is being performed upon her. When a laceration has thus been promptly repaired you have closed up two avenues of future trouble to your patient. In the first place, you have prevented the exposure of the

raw surfaces of the torn perineum to the septic action of the lochial discharge, to which allusion has already been made. I often wonder why it is that all women do not die of puerperal fever after labor. As the patient lies on her back the septic fluid bathes not only the cervix (which is very likely to have been lacerated) and the vagina, but also pours directly over the fourchette, whose lymphatics and blood-vessels have been exposed by its almost inevitable rupture. All this is going on for days and days together, and although vaginal injections may be of service, they cannot prevent it. How much greater must be the danger, then, when not only the fourchette, but perhaps nearly the whole perineum, is torn through, and the extensive surfaces of its two parts left exposed. In the second place, by an early operation the necessary support is furnished to the uterus, and the danger of prolapsus in the future is averted. During the present course I have not had so good an opportunity as the present for speaking of this subject, which I regard as a very important one.

But now, as to the patient before us. Can she be cured? I think she can, but it will take a long time. Under the circumstances here present I would by no means advise that the treatment should be begun with a surgical operation. It is possible to restore this uterus to position and maintain it there by other means, and this will relieve both the engorgement which now characterizes it and the severe dragging upon the ligament which has been going on so long. For this purpose I would suggest Cutler's pessary or some modification of it (which might be removed at night), and in addition copious vaginal injections of hot water should be frequently used, while care should be taken that all pressure from tight clothing be removed. After three months of such treatment as this I do not doubt that we should have a uterus much less hyperæmic and heavy than at present, and it would then be proper to restore the lacerated perineum by an operation. The restoration of the perineal body would thus support the bladder, and all traction having been removed the uterus would probably remain in its normal position without the aid of a pessary or other mechanical contrivance.

CASE III. PROLAPSE OF THE BLADDER FROM RUPTURE OF THE PERINEUM; MARKED RETROFLEXION.

Lena P., twenty-six years old, and a native of Germany. She has been married eight years, and has had three children, but no miscarriages. The last child was born six months ago.

How long have you been sick, Mrs. P.? "Six months." Have you never been well since the birth of your last child? "Yes, I feel well sometimes, but I cannot do my work any longer." Why cannot you do your work? "Ever since my baby was born my womb keeps coming down outside of my body, and prevents me from working as I used to."

Here, you see, we have a diagnosis given us at once, but, as is very apt to be the case under such circumstances, it is not correct. The uterus, I find, has never been down at all.

What else troubles you? "Pain in the back and great distress in the lower part of my stomach." Do you suffer from anything else? "I feel just like fainting sometimes, because I am so very weak." Have you any trouble with your bladder? "No, but I notice that when I pass my water the womb always goes

up, though it comes down again afterward." Do you have to get up at night to pass your water? "No."

From the appearance presented when I first looked at the vulva of this patient, I supposed that the uterus was in reality out of the body, as she stated; but as soon as I touched the supposed uterus with my finger, I found that the mass yielded, and that instead of having prolapsus uteri to deal with, there was prolapsus of the anterior wall of the vagina with prolapsus of the bladder as well. In addition, the examination revealed that the patient had also lost her perineum; and hence it is that the bladder, having been deprived of its normal support, has fallen down in this way, until it is practically entirely out of the body.

But what gives all this pain in the back and the great distress of which the patient speaks? In pursuing my investigation of the case I found, furthermore, that the uterus was completely retroflexed; the cervix being felt very high up, and the fundus down behind it. I thought at first that the latter might be a fibroid (but soon found that it was not sufficiently hard for that), and then that it was a small ovarian cyst which had slipped down into Douglas's cul-de-sac. When I resorted to conjoined manipulation, however, I at once found that the body of the uterus was not in its normal position, and the passage of the sound showed that there was complete retroflexion of the organ. If the diagnosis of prolapsus uteri had been taken for granted here, and a pessary appropriate for that condition ordered, it would have done harm instead of benefiting the patient. A pessary for prolapsus can do no good where there is retroflexion of the uterus, and this is altogether the most marked case of retroflexion that has been at the clinic for at least a year.

The question now comes up, Has all this trouble come on since the birth of her last child, six months ago? I think not; for it is much more probable that the prolapsus of the bladder was the result of her first labor, six years ago. The retroflexion, however, I believe must have followed the last one, six months ago; because it is so extremely marked that I can scarcely see how it is possible that so many conceptions should have occurred with the organ in this position.

This patient, I believe, can be cured; but it will be a very troublesome case to treat. What shall we do first here?—restore the perineal body? If we do, we shall most certainly fail in curing the patient; because this bladder, instead of being of the normal size, is now three times as large as it ought to be, and it cannot be satisfactorily supported in its present condition. The only proper way to proceed here is to begin by reducing the size of this organ, and this can be done most simply by taking an ellipse from its walls, and bringing the denuded mucous membrane together by means of silver wire sutures. After the operation Sims' glass plug should be worn for a time in the vagina, and at the end of nine days the sutures should be removed. Thus having succeeded in markedly diminishing the size of the hypertrophied bladder, the next step will be to restore the perineal body by the usual operation; and the uterus, having then been replaced, should be kept in position by a pessary. When all this has been done for her the patient will imagine that she is cured; but in every such case you should beware of telling the woman that she can get along without wearing a pessary. I should think it

would be fully two or three years before the pessary could be safely abandoned in the present instance, because the uterus has completely lost its tone.

CASE OF PRESIDENT GARFIELD.

STATEMENT OF DR. J. COLLINS WARREN.¹

MR. PRESIDENT AND GENTLEMEN OF THE SOCIETY,—Before making any remarks on our President's case, perhaps it will be proper for me to say that I am in possession of no facts or data that other members of the Society have not had the opportunity of reading and finding out for themselves. The diagrams and one or two other matters of interest which I shall show were collected together for illustration to the class at the Medical School, and I thought it might be of interest to the members of the Society to present them, such as they are, imperfect as the statement of the case would be to them. I therefore offer no further apology for the incompleteness of my remarks. I suppose that it would hardly interest the members, either, to hear all the details which I went into at the school, but I will select certain points which may be of interest to them as physicians.

In the first place I would present for inspection a specimen of the ball with which the President was wounded, No. 44 calibre.—quite a formidable pistol-ball. I will pass it round, together with the pistol, which is of the British bull-dog pattern, which I have here with me. The noticeable features about it are its short barrel, its large mouth, and the fact that it has a repeater, which shows that the assailant was able to fire two shots in rapid succession. In reading one of the sporting papers in the course of the summer I noticed some remarks by the editor on the character of this weapon. Attention was called to its small penetrating power. The shortness of the barrel did not give an adequate opportunity for the rifling to exert its influence. Secondly, the charge of powder which is contained in the cartridge is apt to be diminished in quantity by the grease which is used in connection with the preparation of the cartridge and ball. At all events the amount of powder placed in this shell is apt to be of a variable quantity and of a smaller quantity than a full charge. The result is a low rate of velocity. These facts being taken into consideration the small penetrating power was dwelt upon, the writer concluding with the statement that the bark of such a weapon was worse than its bite. It is a kind of weapon apt to be selected by one unfamiliar with the use of firearms, owing to its formidable appearance and also to the amount of noise which the weapon makes in its discharge.

In regard to the direction of the bullet, I have prepared a skeleton, with a wire, on the end of which is inserted a large size bullet showing the track of the ball, with a wire behind here running somewhat in the direction the bullet came before it struck the body. The point at which it entered the body was in the intercostal space between the tenth and eleventh ribs, about three and a half inches to the right of the spinous process of the adjacent vertebra. On entering it descended pretty vertically, so much so that it grazed

¹ Made at a meeting of the Suffolk District Medical Society, October 29, 1881; see page 470.

the inside of the twelfth rib, inflicting a fracture on that rib also, having previously produced a fracture on the eleventh rib. It then entered the intervertebral substance between the last dorsal and first lumbar vertebrae and continued downward obliquely and forward in its course, and emerged on the median line in front of the spine, that is, near the middle of that dorsal vertebra. It then went about two and a half inches further, and lodged behind the pancreas.

Here [referring to diagram] I may add is the track of the ball as shown in a diagram taken from photographs which were kindly sent to me by Dr. Woodward from the Medical Museum. Here you see the twelfth vertebra, and there you see a probe passing through the hole. I have here the photographs which were sent me, the first one showing the injury to the bone by the ball, the second showing the bone laid open to demonstrate the great injury to the body of that vertebra and the intervertebral substance, and even to some of the bony structures of some of the adjacent bodies.

This diagram shows a section of the body at the plane at which the ball lodged, the general plane which the ball traversed. That is about the level of the last dorsal vertebra. This is a diagram taken from one of that beautiful series of anatomical plates of Braune, which are so satisfactory for the purposes of study. Here we have the body of the vertebra, and here the kidneys, right and left; here is the liver; there is the tip of the spleen, and there is the ascending and there the descending colon. In the centre of all lies the pancreas, which you see looks like quite a large organ, and assumes a much more prominent place in such a section than one might imagine. A noticeable feature of that diagram is that the peritoneum lies entirely in front of the pancreas. There is a whitish line shaded dark at the edges, which winds about the colon, intestines, and liver, but leaves behind it the pancreas and the kidney, so that it is a curious fact that the ball entering the body at that part might go more than half way through the body, and yet not make what is technically termed a penetrating gun-shot wound of the abdomen, that is, a wound which had penetrated the peritoneal cavity.

Another interesting feature about the anatomical relations of the bullet at the point of entrance is that, although it had so much to do with the abdominal region, it really entered above the diaphragm, yet at the same time it did not touch the pleura; the pleura did not come quite so far down at this point, and the ball passed along, as it were, the tendons of the insertion of the diaphragm, then penetrated the point of origin of the psoas muscle, according to the statement of Dr. Weisse, passed downwards, as we have described, passed through the muscular attachments below the diaphragm, and rested, as I said before, near the pancreas. As it passed through the tendons of the insertion of the psoas muscle, and entered a bony partition, it left behind it, naturally, a very small point to trace its future progress, to mark the distant portion of the wound.

Here we have another diagram showing the pancreas and its arterial supply, intended to show the splenic artery. Here is the artery about which much has been said, showing its tortuous course towards the spleen, and lying along the upper edge of the pancreas, the ball passing, as you remember, obliquely behind the pancreas and very near the splenic artery in its course.

There are a number of points connected with the

pathology of the case, which, of course, are worthy of discussion amongst physicians. In the first place, the first clinical symptom of note was the shock. There was a large amount of shock at the time of the injury that did not, I think, receive satisfactory notice in the papers at the beginning of the record of the case. At the time of the injury the pulse was weak and very rapid, and the temperature was below normal. There were also other symptoms — pallor and coolness — of a very marked shock.

There was on the whole a considerable amount of examination of the wound, although it was of a cautious character so far as probing, in the old sense of the term, is concerned. We cannot say, I think, that the wound was unduly probed, that is, the deeper parts of the wound were not meddled with, but from an antiseptic view, we might criticise the introduction of the finger of several surgeons into the wound. For instance, there was a statement made by a physician, I think a homœopathic physician, who was some relation or friend of President Garfield's, in which he states that, hearing of the injury, he went to the White House and found the patient lying so and so, with his clothes on him, and he turned him over on his side, put his finger into the wound, and then exclaimed, "My God, General! You ought to have surgical advice," to which President Garfield replied, "There are about forty of them in the adjoining room, go and consult with them." That shows the impression left upon the President's mind by the examination he had been subjected to. Of course, from an antiseptic point of view, these examinations were not in accord with the prevailing present theories.

In regard to the wound to the liver. At the point at which the ball entered the body there is a reflection of the peritoneum, on the liver from below downwards and from above upwards, so that if the ball had entered the body directly and had penetrated the liver, as was supposed, it would not have injured the peritoneum, because there was no peritoneum at that particular point. In fact, with this route of the ball, it would seem as if there was less chance of injuring the peritoneum than in almost any other route that possibly could have been selected. Then the symptoms of injury to the liver were not present.

Dr. Otis, in his great work, the Surgical History of the War, points out some symptoms. Among them the great hæmorrhage, and the characteristic color of the discharges. A gun-shot injury to the liver is not unlike a gun-shot fracture upon glass. The brittle character of the organ renders it liable to become very much comminuted by the shot. I have here the volume for the purpose of showing that point. Such an injury would be a very severe one, and the fact is that gun-shot injuries of the liver are of a very fatal character. Precisely what the statistics are I do not remember, but a great many die from hæmorrhage, which is a striking feature.

We come now to two prominent features in the course of the case, one near the end of July and the other about a week later, in the early part of August. Those are easily accounted for. The burrowing of pus in the neighborhood of the fracture of the ribs rendered counter openings necessary. First, I think, the wound was lengthened a little, subsequently a deeper opening was made lower down, below the ribs, and at fording much more complete drainage of the wound than before. Then, as the case progressed, the fact

that the outlines of the wound began to show themselves in the neighborhood of the groin, the pus burrowing, as is characteristic of pus, from carious vertebrae along the psoas muscle, and ending at a point in the groin. Speaking of the counter openings for the purpose of drainage, I would mention that Dr. Marcy has just handed me a flexible tube, which he tells me has been devised by himself for getting up a double current. The wound was washed out, I am told, with a tube of this character.

In regard to the drainage of the wound, so far as I can gather from the accounts which I have thus far read, there was no tube left in permanently. At one time it was mentioned in the papers that chicken-bone drainage-tubes had been used. If that was the case, of course they were used under a misapprehension of the peculiar qualifications of those tubes, the object of which is to enable them to disappear and become useless after a certain period of time. They are intended for amputations, as for instance, of an extremity where it is desired that the wound shall heal, and they are intended to play the provisional duty which a cat-gut ligature or suture does to accomplish its work, and then become absorbed later: so that with cat-gut ligatures or sutures, and a bone drainage-tube, it would be possible ideally to do up an amputated stump, as you cover a cut on the finger with a piece of court-plaster, and never remove the dressing until the whole part has become healed, and all the agents which have been used in draining and keeping the parts in position have become absorbed and have disappeared. Therefore, if such a tube was used, it was of little use in such a case as this, where the idea was to keep the wound open all the time.

The washing out of the wound, of the pus cavities, as it was called, which burrowed downward, would involve a washing out of the entire wound, as it was observed at the autopsy.

It was stated to me by a lawyer, that a great point could be made in the defense of the fact that the real wound was never dressed, never was treated by the surgeons, during the whole course of the case; that is, the track in which the ball went, starting from between the tenth and eleventh rib to the spot behind the pancreas. We know a part of that had been obliterated, had healed up, the ball having become encysted, and needed no such treatment. The wound, it seems to me, on more accurate study, was one large irregular cavity, similar in its outline to the ordinary pus cavity in a case of Pott's disease, a tortuous, irregular mass of pus burrowing in different directions, modified somewhat by the two broken ribs, which were centres from which radiated inflammatory tendencies, and that the washing out with the catheter probably effectually cleansed the whole wound.

We come now to the next point of interest, one which is, perhaps, as interesting to the profession as any; the significance of the inflammation of the parotid gland in this case. This brings us to the question of pyæmia and septicæmia. So much was said about these diseases, and so many contrary opinions were expressed as to whether it was pyæmia that the President had, or septicæmia, that I have taken the liberty of bringing a few charts here giving the fever curves of cases of pyæmia and septicæmia, and I will take your time for a moment in rehearsing some of the prominent symptoms of those two diseases, as given to us by modern writers. Let us see, then, what is the character of septicæmia, a poisonous fever arising from

an absorption of the products of decomposition in a wound. Take, for example, an amputation where during the first day or two there had been sloughing of the fat or muscular tissues, the serum of the blood which has been discharged mixing with the decomposed tissues, and there has been some poison generated which has been absorbed. The patient has an unusual amount of fever, an increased temperature, continuing at a high rate, until at the end of a few days death ensues. There has been practically no other symptom but fever, which has been accompanied by delirium, rapid pulse, etc., but no other particular symptom characteristic of a special disease. At the autopsy no particular pathological appearances would be found beyond, perhaps, a cloudy swelling of the liver and some other organs.

Take a case of pyæmia and compare it with that. The patient not having succumbed in the early stages, following an amputation, to a severe attack of fever like this case, suppuration takes place, and having been unusually abundant, the fever curve, instead of going down to normal at the end of a week or ten days has been kept a little above that point. Suddenly the patient has a chill, followed the next day by a chill, and perhaps the next day two chills, and there is a certain discoloration of the skin showing a slight bilious tinge, and the abnormal febrile disturbance continues for a longer or shorter time until death ensues. Before, however, death has ensued there is generally some local manifestation, that is to say, there may be a swelling of the knee-joint or shoulder-joint. At the autopsy pus is found in these joints. Pus may be found in the connective tissue structures, between the muscles of the thigh, for instance; pus may be found in the pleural cavity; small abscesses will be found scattered about in various organs, like the lungs and liver and kidneys. In other words, we have in this case, a disease with marked clinical symptoms, and equally marked pathological *post-mortem* appearances.

Some writers on pyæmia undertake to recognize two kinds: First, that which is caused by the absorption of a poison generated during the process of suppuration; that is, evidently, a case very similar to septicæmia in its origin; secondly, that caused by the dissemination of emboli throughout the different organs. The former is called pyæmia simplex and the latter pyæmia multiplex. Those who recognize these two kinds regard the former simply as the result of a poison which shows a predilection for the connective tissue structures. I spoke of the connective tissue of the thigh, and I find in an article by Heuter, from whom I have just quoted, that we may consider the suppuration of the parotid gland as one of the rare features in the first form of pyæmia, to be classified with suppuration of the connective tissue structures rather than with metastatic abscesses of other organs; that we should regard it rather as a symptom of pyæmia than of septicæmia. The most common form of inflammation of the parotid in febrile disturbance is that known to us in typhoid fever, and also in the malarial and dysenteric fevers of the war.

The multiple abscesses spoken of as seen in the gland in the President's case were due simply to the suppurative infiltration of the gland, the conformation of the stroma giving a carbuncular appearance.

Now the question is, Which of the two diseases we have described did the President suffer from? The increase of fever in the early part of the case, the great emaciation, and the general tendency to extensive sup-

puration render it, it seems to me, extremely probable that there was at that time, and perhaps later still, a decided septicæmic condition of the system; but if we go on further to the last days of the case, we get a very striking clinical symptom similar to those we have already described, that is, on the Friday preceding the end the President had a chill, on the next day another, the next day two, and on the last day a chill, when a sudden hæmorrhage cut short the disease and terminated the case fatally. At the autopsy was found this tortuous wound which was described, a pus cavity six by four inches along the lower borders of the liver, by some supposed to have been actually an abscess of the lower portion of the liver, as the liver itself seemed to be directly involved; by others supposed to be merely a sinus dissecting between the liver and the colon, with a very small amount of pus in it. There was also found an abscess in the left kidney near the cortical portion, and then a peculiar condition of the splenic artery, to which we will allude presently. In the lungs there were no metastatic abscesses. I think the surgeons here recognize the complication of the lungs as showing nothing more than the hypostatic congestion which frequently accompanies surgical cases. With that was a bronchitis, and a free purulent expectoration from the membranes, but no metastatic abscess of any kind.

What light does the autopsy throw on the case? Taking the clinical symptoms, the presence of chills, which are considered so characteristic of pyæmia, we should have expected to find a number of metastatic abscesses after death. There was only one abscess, I think, that we could fairly consider as belonging to that variety, namely, a very small abscess in the cortical portion of the kidney. The larger cavity near the liver, so near the wound, the further portion of the wound directly in front of the spine, has been regarded by some in the light of a metastatic abscess which developed during the last chills. I think that Dr. Hamilton's explanation of it is the most satisfactory. I see that in answer to a reporter he pointed out that as the ball passed the twelfth dorsal vertebra an explosion, as it were, took place in that portion of the bone, the fragments of the bony tissue being scattered broadcast in various directions, causing injuries which produced this long sinus of pus, which may or may not have communicated at some time with the main wound. The pathological appearances, therefore, do not afford us a very complete case of pyæmia. One metastatic abscess is a very small basis on which to build such a diagnosis. But we must remember that an incident occurred at this stage which cut short the disease, namely, a secondary hæmorrhage, and that brings us to the question of the injury to the splenic artery.

It is now stated by Dr. Weisse (I have not seen it stated by any of the physicians in attendance on the case) that as the ball came toward the lower edge of the pancreas it injured the splenic artery, which would be in the course of the ball. It was claimed by some physicians that these chills could have been accounted for by repeated hæmorrhages from the wound in the artery. I should hardly think that any surgeon would agree that the hæmorrhages in this case would cause the chill. That is not a very well recognized cause of chill, certainly, and I should be inclined to object to the theory that hæmorrhage had anything to do with the chill.

In regard to the question of the wound to the artery,

if it had been injured by the ball, there was but one possible termination of the case. The wound of the splenic artery could not be got at, and, in fact, the existence of such a wound could not be recognized in any system of examination with which we are acquainted, and if left to itself it was bound to develop into an aneurism, which would eventually burst and kill the patient. But whether this wound in the artery was made by the ball, or whether it was due to an ulceration of the wall in the course of suppuration is a question upon which, I think, it is but fair and just that we should withhold our opinion until further evidence on that point has been given to us.

Therefore, taking all these facts into consideration, it seems to me that during the last part of the case the President was suffering from marked pyæmic symptoms, which, had they been allowed to go on, would have produced characteristic pyæmic appearances, namely, metastatic abscesses, but that the progress of the disease was suddenly cut short by the hæmorrhage which terminated the case.

I have a chart here which gives the pyæmic temperature, in which an attempt has been made to indicate its peculiarities. I believe the temperature of pyæmia is entirely peculiar to that disease; that is, we have in most diseases a high evening and low morning temperature, comparatively speaking, — only one febrile rise, therefore, in the twenty-four hours. But in pyæmia we should have, not diurnal variations, but hourly variations, and if we would make a careful diagnosis it is necessary to take the temperature at least as often as every two hours. If we only take the temperature morning and evening it might happen that we should have a particularly low temperature in the evening, whereas in the morning we might have taken the temperature on one of the hours of its rise; therefore a morning and evening temperature would be totally inadequate to show this peculiar febrile condition.

Although the fact was not reported in the official bulletins, yet from remarks made by Dr. Bliss I should judge that the temperature was frequently taken in this case. How systematically this was carried out we have not yet been able to learn, but when we do have a complete record of the case (for I hope Dr. Woodward will write out its history and give us all the details) we shall then see whether in the last days of the President's sickness he had this characteristic temperature, this frequent rise in twenty-four hours, and if so, then our diagnosis of pyæmia will be definitely determined.

Gentlemen, I have already taken a great deal of your time, and there are some interesting exhibitions to be made, and I will therefore content myself with making the remarks I have, thanking you for your attention. [Applause.]

— The death is announced of Dr. Giovanni Cabiadis, an authority on the plague, of which disease he had a very large practical experience. He was Sanitary Officer in the service of the Ottoman Health Department, and in this capacity had done much valuable work. Whilst suffering from the effects of an attack of malarial fever he was sent to the Department to superintend the sanitary measures designed to stamp out the plague in Mesopotamia. His disease became aggravated, and his life was really sacrificed in the discharge of his duty. His place will not be easily filled.

THE EPIDEMIC OF TYPHOID FEVER AT NAHANT, MASS.

WE are able to give our readers the following condensation of the report submitted to the selectmen of Nahant by Drs. John P. Reynolds and Thomas Dwight, who were appointed a committee to investigate the cause of the fever, and to make recommendations as to the water supply. The report was read at a town meeting held early in October, and is to appear in print.

The report states that there had been perhaps fifty cases of typhoid attacking persons who either were residing at Nahant or who had left it shortly before the attack. Most of the cases were light, but some had been severe, and two had been fatal.¹ Two theories exist as to the origin of typhoid fever. According to one the poison is conveyed by the discharges of those suffering from the disease, and thus every case is to be traced to some preceding one; according to the other the disease may arise anew from filth and decomposing substances. The committee did not think it advisable to discuss the merits of these theories, as there can be no doubt that, even according to the former, unclean surroundings are most favorable for the development of the disease.

Nahant is certainly exceptionally well situated for health, but this advantage has been counterbalanced by neglect of sanitary precautions, especially in neglecting the cleaning of privies and the placing of vaults and cess-pools at proper distances from wells.

The committee was unable to trace the present epidemic from case to case, but in many instances the surroundings had been found such as to offer a plausible explanation. Special attention had been given to the analysis of wells, but the committee pointed out that polluted water was only one of the means by which fever could be transmitted. The committee had caused to be examined at Professor Wood's laboratory, at the Harvard Medical School, fourteen specimens of well-water (two of which were taken at different points from one well), one specimen of cistern water, one of melted ice, and one of milk from one of the chief suppliers. They had access also to the results of seven other analyses made by Dr. Wood for private parties, and to four made by Mr. Samuel Cabot, Jr. The ice, unfortunately, was melted without proper precautions, but as it had not been considered suspicious, and as even then the analysis showed nothing wrong except somewhat more albuminoid ammonia than should be found, the experiment was not repeated, and the result simply ignored. The milk was pronounced very good. Dr. Wood, however, added that he was not aware that chemical analysis could determine its capability of conveying typhoid fever. The cistern water was very bad, containing .1125 parts of free ammonia and .0200 of albuminoid ammonia in one hundred thousand parts of water. One well contained .2340 of free ammonia and 80 parts of residue. Several other wells were found more or less suspicious. In some cases the disease could be traced to filth conveyed in other ways. As the town had appointed a sanitary expert the committee made few suggestions. As the specimens of water had, for the most part, been collected in a dry season they recommended that certain wells should be examined again after a period of

rain, which very probably would render some suspicious which as yet were not to be condemned, and others very bad which as yet were only suspicious. They advised that certain wells should be absolutely condemned. As the committee could not pretend to say how soon a bad well might become good after the cause of pollution was removed, they advised at least that the prohibition should not be taken off till chemical analysis should give every assurance of safety. Vaults and cess-pools should be cleaned and disinfected, and in some cases where vaults or cess-pools were near wells it was evident that one or the other must be condemned.

With regard to water supply, the committee pointed out that any plan which would give a large amount of water would be a positive evil by increasing the danger unless it include an elaborate system of drains.

We are informed that the town has purchased an odorless suction apparatus to empty vaults and cess-pools, and that the question of having these built so as to be tight and having them emptied at proper intervals has been considered.

RECENT PROGRESS IN DERMATOLOGY.

BY E. WIGGLESWORTH, M. D.

EPILATION FOR FAVUS.

PARASITIC disease of hairs calls for their removal, and epilation of large surfaces with forceps is a slow process. For many years the calotte was employed. This is an adhesive plaster which is applied to the part, after the hairs have been shaved, and the sudden and violent removal of which eliminates the hairs *en masse*. It is still in use in Italy, where it originated, but has been gradually given up, as too barbarous, elsewhere. Dr. Bulkley recommends² *cerae flavae* 12; *laccæ intabulis* 16; *resinae* 24; *picis Burgundicæ* 40; *gummi danmar* 48; thoroughly mixed and rolled into sticks of various sizes. These may be used, like a calotte, for larger or smaller spots, the hair having been cropped to a length of three millimeters. Heat the stick in an alcoholic flame, press quickly upon the hair with a slightly rotary motion, leave till cold, and remove by bending over and slightly twisting. The end will be thickly set with the removed hairs, like a bristle brush. To prepare the stick to use again, burn off these hairs in the flame, and wipe the end of the stick firmly on a sheet of paper. This destroys the parasite while cleaning the stick for subsequent use. Subsequently employ parasitocides.

TRAUMATISM IN THE ETIOLOGY OF FAVUS.

Aubert calls attention³ to the fact that, the fundamental etiology of favus being the presence of the parasite *achorion Schenleinii*, there still remain secondary causes, a knowledge of which, these causes being accessible, may help us to a prophylaxis not to be obtained from a notion of a primary cause which may escape us. Thus, the parasite must exist somewhere; it must, then, somehow be brought in contact with the subject attacked; this subject must have an integument fitted for the reception and growth of the fungus. Aubert believes that the condition of the skin favors or impedes planting and germination, and

¹ Several cases have occurred since this time, and there has been at least one more death.

² Reprint from Archives of Dermatology, April, 1881.

³ Annales de Dermatologie et de Syphiligraphie, April 25, 1881.

that abrasions or wounds are especially favorable to the reception and propagation of the spores. For instance, inoculations are rarely successful if the spores are merely spread upon the skin; they must be forced into dilated and wounded follicles for the skin to accept them. Sex, age, uncleanness are all, he thinks, less important factors than traumatism. In December, 1880, there were 37 cases of favus in Dr. Aubert's hospital wards. Examination showed, among 13 girls, traumatic origin 3; non-traumatic 5; doubtful 5; 24 boys, traumatic origin 6; non-traumatic 14; doubtful 4. That is to say, 9 traumatic cases out of 37; about 25 per cent. During 1879 and 1880 sixteen marked cases were observed where exposure prior to wounding of the skin for long periods produced no effect, while soon after injuries favus developed, starting from the point of injury. Gailleson reports four such cases, one being of rats kept in a cage and examined carefully. Aubert has seen in his own wards circumscribed patches of favus develop upon eczematous areas, or where croton oil had been employed upon the scalp. So, also, anæmic, scrofulous children with pediculi upon the head are very prone to acquire favus. Favus of the nails is very rare, and for the simple reason that patients, when they scratch, do not employ wounded fingers as their implements, it being equally easy to use the sound ones. These facts have an important bearing upon the prophylaxis of the malady in schools, infant hospitals, orphan asylums, etc.

MORPHEA ASSOCIATED WITH ALOPECIA AREATA.

Jamieson records¹ a case of well-marked morphea, characterized by almost perfect symmetry, distinct localization along nerve tracts, and association with alopecia areata of the head and beard. On each side of the abdomen, from the umbilical and hypogastric regions, over the groins, flanks, and thighs, extended white, smooth, punctated, ivory-like areas, lardaceous and slightly thickened, and darkly pigmented areas sprinkled with lighter spots, with others faintly violaceous, these last preceding the white spots in point of time. Over the sacrum was a large lilac patch surrounded by smaller ones. On each side of the spinal column were many faintly tinted ones, roughly corresponding to the emergence of the posterior branches of the spinal nerves. Some followed the course of the intercostal nerves. A large patch upon each arm stretched from the external condyle of the humerus down the outer aspect of the forearm, and patches at intervals ran longitudinally down the back of the thigh and leg as far as the ham. No subjective sensations. Neither anaesthesia nor hyperaesthesia. Upon the white spots the lanugo was deficient or absent. The patient was treated with arsenic, iron, quinine, and strychnia for a month without any improvement. At the end of that time a patch had appeared upon the right side of the chest, extending downwards from the axilla nearly to the ilium and umbilicus, its centre brown, its border, an inch broad, violaceous. This border possessed an extreme margin, lilac in color and well defined; within this the color was still faintly violet, with a whitish gleam, and showing a speckled or stippled appearance. A few whitish spots were scattered over the darkly pigmented central area. The inner part of the margins was waxy, slightly elevated, and depressed in aspect. Lilac patches existed upon the thigh, ham, and calf. A closely correspond-

ing condition existed upon the left side of the body. Posteriorly a triangular violaceous patch, its base at the vertebra prominens, extended downwards; its apex at the dorsal vertebrae. Over the sacrum a transversely ovoid patch of lilac spots. A spot existed over the deltoid of the right arm, and patches on upper and outer aspects of both forearms. Hair returning upon the head but not in beard. General health good.

LICHEN PLANUS OF PENIS.

Bulkley communicates² a case of lichen of the penis, and appearing also there alone before manifesting itself elsewhere. It adds another to the long list of dermatological lesions, non-venereal in nature, which may appear in this locality. We have ourselves seen psoriasis of the glans penis, the rest of the body remaining for more than a month free from all signs of the malady. The moral appears undignified, but is pardonable from its exceeding utility to the average general practitioner, namely, a gold watch is not a moribund cucumber, though found in a pig-pen. A small spot, purplish red and slightly elevated, was first noticed upon the anterior portion of the glans. Some six weeks later other small, more or less circular, spots appeared near the first, all of the same character, slightly elevated, flat on the top, and tending to run together, forming large plaques, all of the same pinkish-purple color, non-indurated, without subjective sensations, smooth, slightly shining, and without desquamation. The patch increased only slowly in size, but three months after the appearance of the first spot upon the penis the patient again presented himself with a perfectly developed lichen planus upon the forearms, and, although to a less extent, upon the abdomen and chest, all having appeared during the last two or three days. The lesions on the penis were still in much the same condition as at the previous visit. Two and a half months later, under treatment by arsenic, nitric acid, etc., all appearances upon the penis had vanished, leaving a slight pigmentation. The lesions upon the body disappeared some three months later under careful dietary and medicinal treatment, their entire duration being about the same as that of those upon the penis.

AUSPITZ'S SYSTEM OF DISEASES OF THE SKIN.

Since Hebra published, in 1815, his dermatological system of nomenclature and classification, no complete classification, in accordance with subsequently acquired knowledge, has been till now attempted. Dr. H. V. Hebra criticises³ at length Auspitz's volume of 250 pages devoted to an attempt at a more scientific classification than has previously existed. The details are interesting only to specialists. Auspitz's general division is as follows:—

Class I. *Dermatidites Simples*. Simple Inflammations.

Class II. *Angioneurotic Dermatoses*. The results of impairment of tonicity of vessels, with more or less marked inflammatory elevation of the surface of the skin.

Class III. *Neuritic Dermatoses*. Due to affection of nerve elements (sensitive, and perhaps also trophic).

Class IV. *Stasis Dermatoses*. With the character of

² Proceedings American Dermatological Association, 1880.

³ Separat Abdruck aus Nos. 1, 2, 3, und 4 (1881) der Wiener Mediz. Blätter.

¹ Archives of Dermatology, April, 1881.

passive disturbance of circulation and marked venous-lymphatic absorption.

Class V. *Hæmorrhagic Dermatoses*. Such as result from excessive exudation of red blood corpuscles through the walls of vessels, without inflammatory exudation or local stasis.

Class VI. *Idioneuroses of the Skin*. Functional anomalies of cutaneous nerves without trophic disturbances.

Class VII. *Epidermidoses*. Anomalies of growth of the epidermis and its appendages.

Class VIII. *Chorioblastoses*. Anomalies of growth of the derma and subcutaneous connective tissue.

Class IX. *Dermatomyceses*. From vegetable parasites.

The volume evinces the author's acquaintance with, almost literally, everything ever written upon the skin, and a dermatological, pathological, and general medical knowledge of the highest order. It shows vast labor and originality, and stimulates in the highest degree to future progress in the direction of an exact, scientific classification of that family of diseases which, lying directly under the eye of the observer, is easiest to study and promises the best results to the research of future investigators.

SYPHILIS OF MENINGES AND RETINA.

Lang adds ¹ to his observation upon the "meningeal irritation" of early syphilis ² the results of his studies since pursued in the same direction. The condition is one of hyperæmia and rarely advances to actual inflammation. Functional action is not influenced, pulse unaltered, temperature only infrequently raised, and then but slightly; in two cases slight paralysis existed, and here for a brief period only; pain existed over the whole skull, or occupied the region alone of the forehead or occiput; at times, however, a band, painful, and as if due to constriction, crossed the skull horizontally, from one ear to the other, like a bow; occipital neuralgia existed in one case; vertigo, nausea, loss of appetite and spirits were the usual concomitant sensations, and, as the rule, were of short duration, though in a case of Professor Schnabel's the occipital neuralgia was more lasting. Schnabel,³ at Lang's request, examined all the latter cases with the ophthalmoscope and ascertained the presence of inflammation of the retina, or choroid, or both, in many cases, although the patients had not complained of any trouble in their eyes. Something is, therefore, to be awaited in the future from the ophthalmoscope as a means of diagnosis, for the condition of the retina can be ascertained when meningeal irritation is only to be surmised. On the ground of clinical experience Lang has asserted since 1871 the existence in syphilis of an organism, a *contagium animatum*, not as yet recognized. This enters the blood current, passes everywhere, is destroyed in most parts, but not in all, and its living presence is shown by the resulting conditions. Then he asserts that an organ affected by a gumma must have been affected irritatively during the early period of the general disease. Diday and Doyon hold views somewhat similar. Hutchinson regards syphilis as past when the early symptoms have disappeared, the late appearances being sequela merely, as after other acute exanthemata.

LEPROSY.

Campana furnishes ⁴ the results of his anatomical investigations upon a case of tubercular and anæsthetic leprosy with recurrent bullæ upon the face and left hand, scabs upon the left foot, enlarged spleen, icteremia, ulceration of soft palate and larynx, adhesive pericarditis; concentric hypertrophy of the left ventricle, partial peritonitis, partial interstitial hepatitis, perisplenitis, interstitial neuritis, hyperplasia generally of the lymphatic glands, and cutaneous and muscular atrophy of the left forearm. Histologically, some peculiarities were observed which have hitherto escaped notice. Thus the adventitia of the vessels running in the connective, under the serous, tissue of the visceral pericardium, but not entering the myocardium, were notably thickened, while under the visceral pericardiac layers there existed a disseminated granuloma (infiltration of endothelial elements and of cells like leucocytes) in spots or reticulated, with accumulations of connective-tissue cells in the sub-pericardial adipose cellular tissue. There was also granuloma of the nerves, as well as the changed conditions in both vessels and nerves to which other observers have already called attention.

URTICARIA.

Rohé attempts ⁵ a rational solution of the unsettled problem of the pathology of urticaria, which he regards as neuropathic in its nature, basing his theory upon the experimental evidence of Stricker's investigations,⁶ following the opinion of Auspitz. Clinical evidence in favor of the neurotic nature of urticaria exists in many cases, markedly those of Leopold, Bulkley, Walton, and Charcot. The treatment of acute cases is anything or nothing, with an emetic or purge and some antipruritic lotion. Chronic cases, on the contrary, are troublesome. Regulate every bodily function in the least degree abnormal. If attacks show periodicity try full doses of quinine or, this failing, arsenic. Salicylate of sodium 1.50 grammes, *ter die*, has been followed by prompt cure in some persistent cases. Schwimmer reports success with one milligramme doses of atropia sulphate. Pick reports brilliant results with pilocarpine. The fluid extract of jaborandi may give good results. With these may be used externally one gramme benzoic acid in one hundred and twenty-five grammes water as a lotion sopped on to the skin.

ONYCHOPATHOLOGY.

Unna publishes ⁷ some investigations upon the anatomy and physiology of the nails, a much neglected subject. The matrix of the nail extends from the furrow of the integument posteriorly to the anterior border of the lunula. The whole nail is here formed, sharply beveled at its origin, thickening in the furrow, but taking up no new elements when once the lunula is passed. It then merely slides forward over the nail bed pushed on by the pressure from behind. Left to itself it would bend over the end of the finger like a claw, scaling off at its free extremity and thus keeping itself sharp. The nail receives, therefore, no accession of elements from the nail bed [and Dr. H. V. Hebra goes farther than Unna in that he thinks that the biconvex lunula itself furnishes no special nail elements, being devoid of papilla; and that the whole nail takes its origin pos-

⁷ Viertelj. f. Dermatologie und Syphilis, viii. Jg., 1881, 1 Heft.

teriorly from the basis of the furrow where the papillae of the corium do exist]. Each papilla shoots up a column of cells and these columns are, like blades of grass or grain growing in a field swept smoothly down by the wind, bent, by the pressure of the integumental fold above them, downwards and forwards, and constitute the nail by their aggregation. The nail is thus made up of columns, sloping from below and behind, upwards and forwards, and its thickness depends upon the angle of inclination of these columns of cells to the nail bed underlying them. Thick nails, therefore, need cutting less frequently than thin ones, though growing equally fast; for we cut our nails transversely and not in the plane of these cell-columns, thus removing, in the thick nails, vertical, in the thin, horizontal, growth. The cell-columns formed from the anterior portion of the matrix remain in front of the overlapping columns formed behind them, throughout the whole nail, as it grows forward towards the end of the finger, and a morbidly thin nail would therefore arise from increased cell production anteriorly, since here the overlapping columns would be left behind in the race of growth. Conversely, diminished cell growth from the posterior part of the matrix would give the same result. So also a reversal of either of these conditions would give rise to an abnormally thickened nail, and also account for its tendency to become claw like. Localized transverse, or longitudinal, hypertrophies or atrophies, are, in the same way, the results of localized transverse, or longitudinal, origins of increased or diminished cell production. The splitting of nails may also be due to these pathological conditions, or a convex or concave free border of the nail, according as the middle layer of cells is more or less abundant than those above or below, that is, those formed posteriorly or anteriorly. In these cases we can hardly speak of hypertrophy and atrophy of the nail, those terms being properly applicable only to the relative excess, or deficiency, of general cell production over, or below, exfoliation, which last represents, for epidermal growths, what disintegration and absorption do for other tissues. Destruction of the whole matrix means destruction of the nail as, for instance, from ulceration. On the other hand, eczema, psoriasis, etc., affecting the integument and the posterior part of the matrix, affect only the upper layers of the nails. Should the nail be absolutely cut in two, the anterior aspect of the posterior portion becomes thick and blunt. So, to a certain extent, when a nail has been lost and is renewed from the matrix. This condition remedies itself in time, as the rule, but may, by exerting pressure, hold back and heap up the advancing cells behind it and call for thinning by scraping and for constant pressure, as by a finger cot. On the other hand, intermittent pressure may be used to thicken and harden nails following the analogy of calluses, corns, etc. Pressure sideways, as from tight boots, may round up the nail bed, causing thinning of the true nail, which is squeezing forward over it. This calls for pressure from above downwards. Thickening of the integument under the nail, or syphilitic ulceration from before backwards, may raise the nail from its bed, admit air, the nail becoming yellowish white, and cause loss of nail back to the matrix. In the latter case the nail may break off unnoticed by the patient. Abnormal spots upon the nails regularly and continuously advancing in a straight line point to affections of the matrix; those not changing their location to affections of the nail bed. Another secondary degenera-

tion is that from fungi. Here the nail is usually affected from the nail bed below it, and the process works from before backwards, rendering improbable any origin of the process in the matrix.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

H. C. HAVEN, M. D., SECRETARY.

STATED meeting, OCTOBER 29, 1881. DR. R. M. HODGES in the chair. DR. J. C. WARREN reviewed

THE CASE OF PRESIDENT GARFIELD.¹

After some discussion, Mr. R. S. Jennings, present by invitation, explained by diagram the

COOLING APPARATUS

used at the White House.

This diagram represented the apparatus used in the White House during the President's illness. It was introduced the sixth day after the shooting and was located in the basement of the house, about forty feet from the register in the President's room. The air was taken from over the door at the western entrance and passed through the machine and into the flue leading from the basement to the State dining-room on the floor above, and then to the register in the President's room on the floor above that, a distance of about forty feet from the machine. The register in the State dining-room was sealed up and the one in the President's room kept wide open, the temperature of the room being regulated by the speed of the machine, as ordered from the physicians' room by telephone, put up for the purpose. The windows of the room were kept constantly open after the first few hours' trial of the apparatus, the President and Mrs. Garfield both objecting to their being closed. The bed was located about twenty feet from the register, and had a low screen in front of it to protect the patient from any current of air.

The average temperature of the air as it entered the room at the register was 50° F., and at the bed 75° F., and the instruments used for testing the humidity of the air always showed that the air averaged about two degrees dryer in the President's room than in the adjoining rooms.

The construction of the apparatus is as follows: This lower chamber is of cast iron, ten feet long, three feet high, and three feet wide, and is filled with vertical horizontal iron frames covered with Turkish towelings. These frames are arranged vertically and horizontally and represent some three thousand cubic feet of cooling surface. The upper tank is of galvanized iron, and six inches smaller each way than the lower one. This chamber is filled with ice and salt, upon which a fine spray of water is allowed to play, percolating through the ice and salt into a perforated coil of pipe, arranged over the three thousand feet of cooling surface in the lower tank, keeping them constantly wet at a temperature of 33° F. The exhaust fan, shown at the left, draws the air to be cooled in through the pipe at the right hand end of the machine and between the cooling frames (most of the reporters state it that the air was drawn or forced through the fibrous screens). The air in passing between the screens be-

¹ Vide this Journal, page 463

comes literally washed and dried, the pulsations of the pump or fan creating a constant flapping together of the wet surfaces, the air being dried by condensation. This machine required less than a horse power to run it, and, using six hundred pounds of ice and thirty pounds of salt per day, supplied twenty-three thousand cubic feet of air per hour, at about forty degrees at the outlet of the apparatus and fifty degrees at the register, forty feet distant. When the weather was very warm a larger quantity of water was allowed to run upon the screens, thereby using more ice. This apparatus may be run with a small water motor requiring a stream of water no larger than a lead pencil, under the usual city water pressure, and the screens may be kept wet with a spray of hydrant water, and a reduction of ten to fifteen degrees secured, well water giving a still greater reduction, and ice and salt, as described, giving a still lower temperature. An apparatus on this principle, five feet high and fifteen inches square, resembling an ordinary card table in appearance, using fifteen or twenty pounds of ice per day, and run with a spring motor, similar to a clock movement, and working without any noise whatever, would reduce the temperature of a room, sixteen by sixteen feet square, and ten feet high, from 95° to 65° F. The cost of such a machine would probably not exceed twenty-five or thirty dollars, and would be of great value in the sick room, using dry ice and salt.

The principle is adapted to a great variety of mercantile and mechanical pursuits, but as they are, perhaps, foreign to subjects introduced here, I will only say further, that I shall be pleased to answer any questions or give any information in my possession on the subject.

Dr. GARRATT also exhibited a cooling apparatus, and explained its operation as follows:—

Mr. President, — I have the pleasure of calling your attention to a very small apparatus, which shows in great contrast to the large cooling apparatus you have had shown you this evening that was actually in use for cooling the President in his sickness. This was also made expressly for the President at about the same time, and would not have had an existence here had it not been for his sickness. It has been seen by no one but myself except one or two physicians. It was made in the first week in July when the President was suffering so much, and I was about to ship it when the news came that the medical attendants had a very large and efficient apparatus which was making him comfortable. The apparatus was then taken back to my office and put away, and has remained in the dark from that to this, when we saw a notice in the paper that this question was coming before the Medical Society, and I thought it was no more than right that Boston should show that we tried, even with a small apparatus, to help the President, although it was not found efficient like that larger one.

The aim of this was to cool the bed. It was a matter I had been thinking of a great while, and it came up fresh to me on the morning of the 5th of July. On that morning news came from Washington that the President had suffered greatly on the 4th from heat, and between eight and nine o'clock I telegraphed to Dr. Bliss, suggesting to him politely to raise a box with three or four hundred pounds of ice in it over the sick-bed, so as to let cold air out, catching the drip in a pail, and to look for a letter fully explaining what the arrangement was.

Gentlemen here will recollect that years ago I brought this matter to the attention of the Society of elevated ice to cool the air over the sick. It was referred to a section. The apparatus was small, and simply illustrated the principle; it was taken to Dr. Bowditch's house, and placed upon a table, but was so small it was not found practical. It was not a quarter the size of what I had used, and as I had used it in only two or three cases I dropped it. Naturally this thought came to me when the news arrived that the President was suffering so intensely from heat, and when I telegraphed this suggestion the papers brought back word that the Boston method had partly failed. Why? Because they did not elevate the ice. I set men at work preparing this apparatus, and attempted to ship it.

This is the history of the device. It is simply a cylinder containing broken ice. The air is passed down through it. By pulling off the caps at the bottom the cold air will rush through of itself. By putting a pipe on the cold air is forced out, and the pipe could be made to lead to the patient's bed, or to his face, or any part of the body, or it would diffuse itself over the whole bed.

Dr. Garratt then explained the operation of the apparatus by working it, stating that the only noise it makes is a little buzz, which would be comparatively beneficial rather than otherwise.

SEVENTH ANNUAL MEETING OF THE TRI-STATE MEDICAL SOCIETY, ST. LOUIS, MO.

THE seventh annual meeting of the Tri-State Medical Society was opened in the Ladies' Ordinary of the Lindell Hotel, St. Louis, on the morning of October 25th. The Society embraces the States of Illinois, Indiana, and Kentucky, and the cities of St. Louis and Cincinnati, which latter, however, furnished no delegate to this convention. The number of delegates appointed from the various local medical societies of the above-mentioned places numbered about two hundred, but a great many failed to present their credentials, and the attendance was not as large as had been expected. There was no lack of interest or good feeling among those present, however, and no doubt those who did attend have been amply repaid for coming. Three sessions each day were held, — morning, afternoon and evening, — and the following programme was offered.

It was not strictly adhered to, however, as many of the authors were absent and their places were supplied by volunteer contributions.

The papers were as a rule interesting and instructive, but among so many only a few can be noticed.

First Session, Tuesday Morning, October 25th, nine o'clock. (1.) Call to Order. (2.) Statements of Officers and Committees. (3.) President's Address. (4.) Medical Orthodoxy, T. D. Washburn, Hillsborough, Ill. (5.) Pediatric Practice, G. Wheeler Jones, Danville, Ill.

Second Session, Tuesday Afternoon. (1.) Convulsions in Children, J. M. Henry, Rockport, Ill. (2.) Scarlatina, D. S. Booth, Sparta, Ill. (3.) Diphtheria, W. J. Chennoworth, Decatur, Ill. (4.) Practical Observations in Typhoid Fever, H. V. Ferrell, Carrierville, Ill.

Third Session, Tuesday Night. (1.) Impotence, Ruben A. Vance, Cincinnati. (2.) The Mechanical Treatment of Bilateral Paralysis of the Crico-Arytenoidei-Postici and Post-Nasal Catarrh, B. Tauber, Cincinnati. (3.) Certain Intra-Ocular Affections, William Dickinson, St. Louis. (4.) Suppurative Inflammation of the Middle Ear, J. E. Harper, Evansville, Ind.

(5.) Human Temperature, Normal and Abnormal, Charles T. Reber, Shelbyville, Ill.

Fourth Session, Wednesday Morning, October 26th. (1.) Fracture of the Radius; Treatment by Rubber Bandage, Edward Borch, St. Louis. (2.) Use and Abuse of Splints in Fractures about the Elbow, Heber Roberts, Carbondale, Ill. (3.) Excision of the Larger Joints, J. M. Holloway, Louisville, Ky. (4.) Reformation of Bone, J. E. Link, Terre Haute, Ind.

Fifth Session, Wednesday Afternoon. (1.) Report on Battery's Operation, J. N. McCormick, Bowling Green, Ky. (2.) Peritonitis, Archibald Dixon, Henderson, Ky. (3.) Puerperal Eclampsia, C. D. Pearson, Indianapolis, Ind. (4.) Puerperal Septicæmia, S. H. Charlton, Seymour, Ind.

Sixth Session, Wednesday Night. (1.) Observations on the Use of Static Electricity, Edwin Walker, Evansville, Ind. (2.) Superficial Diseases of the Eye, William Cheatbam, Louisville, Ky. (3.) Demonstrations of Visual Anomalies, John Green, St. Louis. (4.) Associated Movements of the Eyes and Indications for Prismatic Glasses, A. E. Prince, Jacksonville, Ill.

Seventh Session, Thursday Morning, October 27th. (1.) Headache, Cause and Cure, B. M. Griffith, Springfield, Ill. (2.) Spinal Irritation, J. S. Jewell, Chicago. (3.) Reflex Contraction of Corpora Cavemosa, J. T. Hodgen, St. Louis. (4.) Hyoscyanin in Nervous Diseases, C. H. Hughes, St. Louis.

Eighth Session, Thursday Afternoon. (1.) Care of the Insane, H. Wardner, Anna, Ill. (2.) Ligatures, C. H. Todd, Owensboro, Ky. (3.) Pylephlebitis, Portal Thrombus, etc., J. Adams Allen, Chicago. (4.) How to give Tone to Weak-ned Hearts, W. M. Fuqua, Hopkinsville, Ky. (5.) Thoughts on the Social Evil, J. Gardner, Bedford, Ind.

Ninth Session, Thursday Night. (1.) Stump Water, E. S. McNaire, Mitchell, Ind. (2.) Intussusception, A. P. Berry, River Vale, Ind. (3.) Reports of Cases, J. W. Thompson, Paducah, Ky. (4.) Vaginal Fi-tula, W. A. Mathews, Louisville. (5.) Penetrating Gun-Shot Fracture of Skull-Case, F. J. Gutz, St. Louis.

The meeting was called to order by the President, Dr. A. M. Owen, of Evansville, Indiana, who, in his opening address, gave a brief outline of the history of the Society as follows: The Tri-State Medical Society had its origin in the Indiana Mitchell District Society, and the resolution for its organization was introduced by the present Secretary, Dr. G. W. Burton. The meeting of organization was held at Vincennes, Ind., on the fourth Tuesday of October, 1875. From small beginnings it has grown to be the most important medical society—outside of the National Association—in the country. In conclusion, he alluded to the Social Evil question and expressed the hope that it might in some way be regulated by law. He hoped that there would be a free discussion of the subject, and some plan devised to subdue or hold in check this mighty evil which is now attaining such vast proportions in our cities. Discussion was, however, postponed, and no action was taken on the subject during the meeting.

Dr. Washburn advocated less subjection to the canons of so-called medical orthodoxy, and a freer and more intimate association with other schools. He himself would not hesitate to meet in consultation a homœopathic eclectic, or anybody else, if only he knew him to be a man of sense. His remarks were not received with unanimous favor, and the sense of the meeting seemed to lean the other way. The Doctor desired legislative action in the Western States forbidding any medical college to receive any one as student who could not pass a good English examination. Dr. Hancock, of the Illinois State Board of Health, agreed with the speaker, in regard to the necessity of raising the standard of medical education, and suppressing many of the smaller schools; but thought legislation on the subject difficult. On the whole, he considered that the law in Illinois worked as well as any, though some States, New York for instance, had laws which looked better on paper.

In the afternoon session Dr. D. S. Booth, of Sparta, Illinois, read a paper on Scarlatina, giving cases from his own practice, the peculiarities of which were insidiousness of invasion and hybridism with other diseases. He said that another doctor had visited patients in a tenement house and pronounced the disease to be measles. The other families, not being afraid of this disease, remained in the house and several of their members died of scarlatina. He concluded by giving the usual modes of invasion of the disease in question.

Dr. W. J. Chennoworth, of Decatur, Ill., followed with a paper on Diphtheria. He considered tracheotomy of little benefit in severe epidemics, and that the medical treatment ought to be governed by the special indication of individual cases.

Dr. Wm. Porter, of St. Louis, agreed with the latter idea, and held that the septicæmia in most dangerous cases arose from the retention of some of the poisonous matter in the alimentary canal. Therefore he believed in the use of slight aperients, sometimes of purgatives, amongst others, of large doses of calomel.

Dr. Buck had used the following formula in a case with very pronounced false membrane. In a two-ounce mixture he put fifteen or sixteen drops carbolic acid, half an ounce of pinus canadensis, and the remainder glycerine; with this the throat was painted, and the same mixture diluted used as a gargle. In addition he used chlorate of potash, quinine, and whiskey.

Dr. Reber thought the gagging and straining did more harm than the application did good, and rather discolored any swabbing.

Dr. H. V. Ferrell thought that he had seen typhoid fever originate *de novo*, noting cases where the disease had broken out in families living under the best hygienic conditions. He claimed that remittent fever is fast disappearing in Southern Illinois, and typhoid taking its place. He considered rest and alimentation an important part of the treatment. In the discussion the opinion of Eastern physicians that there is no real typhoid fever in this Western country, but only typho-malarial, was severely criticised.

Dr. Hughes, of St. Louis, considered the name typho-malarial a very convenient and desirable one. He indorsed the views of treatment advanced in the paper, but had added a hypnotic in the stage of delirium, generally chloral hydrate, so as to secure cerebral rest during some part of the twenty-four hours. He was in the habit of giving a small amount of ammonium bromide during the day to tranquilize the patient.

Dr. Reber suggested as a good preventive of delirium and prostration twenty-grain doses of sulphite of soda four times a day. Dr. Ferrel said that one peculiar feature of the disease in his locality was that it was generally better treated without the use of quinine.

Dr. J. G. Carpenter, of Kentucky, presented a volunteer paper on a case of traumatic tetanus successfully treated.

Drs. Vance, Tauber, and Harper being absent their papers were omitted.

Drs. Dickinson and Reber presented their regular papers, and Drs. Carter, of Evansville, and Byrd, of Quincy, presented volunteer papers, the former on the Autopsy of Garfield's Body, and the latter on Lumbar Colotomy in the New-Born, with a case.

Dr. Carter's paper was based upon the official report of the case and autopsy as published in the *Medical Record*. His conclusions were as follows:—

"The assassin's bullet did not make an opening in the abdominal cavity. The surgeon's probe did.

"The wound did not cause septicæmia. The false passage did.

"The bullet did not wound the arteries and cause the aneurismal sacs. The carbolic acid poisoning did (by softening the tissues).

"The blood pressure did not rupture the sacs. The embalmer's force-pump did."

Many of Dr. Carter's statements were called in question, and the general impression of the meeting was that there had been no injurious probing, and that the treatment in the case should be indorsed, an opinion that had previously been officially expressed by a vote in the St. Louis Medical Society.

Dr. Borek's plan of treating fracture of the radius was to apply a straight splint, just the shape of the arm, or it anything a little narrower, to the palmar aspect of the limb, and after well padding it to apply a rubber bandage in the ordinary way. The objection was raised that this had a tendency to press the two bones together, and thus encroach upon the interosseous space, interfering with the movements of pronation and supination. Dr. Borek met this objection by sufficient padding on the splint to press the bones apart. The objection seems to be well founded. The advantages claimed are ease of application and the maintenance of steady, regular pressure on the parts.

Dr. Prince read a portion of his paper on Extrophy of the Bladder, and then presented it in printed form.

Dr. W. S. Ross read a paper on the Prevention of Vesical Calculus, which was published in the *Medical and Surgical Reporter* for September 10th, and exhibited a simple device for cleaning out the bladder.

As none of the gentlemen who were to present papers at the fifth session were on hand, Dr. Ireland, ex-president, gave an address on Puerperal Fever; this opened up considerable discussion, which finally turned upon peritoneal surgery and antiseptics.

Dr. Bauer considered that the only good in Listerism was its "absolute cleanliness." He used cold water instead of carbolic acid or phenol with equally good results.

Dr. Schenck referred to the immense amount of literature and opinions on the subject, and thought the profession ignorant on the question and in need of instruction. "In fact, peritonitis, metritis, septicæmia, pyæmia, and everything was included under one head." He declared that there was an infinite difference between septicæmia and puerperal fever.

Dr. Burton moved that at the next meeting a day be set apart for the discussion of the whole subject of puerperal fever.

The feature of the sixth session was a Demonstration of Visual Anomalies, by Dr. John Green, of St. Louis.

[This paper will be reported in full at another time.]

Dr. B. M. Griffith, of Springfield, Ill., read a very interesting paper on Headache, that opprobrium of medical science. He made an extensive classification of its causes, and recommended that treatment be directed to the cause rather than the effect merely. Eye-strain, he said, was a more frequent cause than was generally believed, and glasses to correct any inequality in vision should be at once adopted in such cases. In the discussion the use of a constant current from the frontal lobe to the medulla was highly spoken of.

Dr. Hughes, of St. Louis, was down for a paper

entitled Hyoseyæmia in Nervous Diseases, but instead read one on Insanity in Relation to Law, on which there was no discussion.

Dr. Hodgen, of St. Louis, followed with Reflex Contractions of the Corpora Cavernosa. This was a report of nine cases, two of which had been previously reported before the Missouri Medical Association. The peculiar feature in these cases was a circumscribed, depressed hardening of either one or both corpora. There was some tenderness to lateral pressure, not to direct. This apparent induration caused the penis, on erection, to curve to one side or the other or upward according as one or both corpora were affected. From the various dissimilar causes of the affection he concluded that it was due to nervous influence, and decided that the hardening was due to a reflex contraction of the muscular fibres found in the fibrous trabeculae of the corpora cavernosa, which reflex action may be set up by various peripheral stimulants, as cold, fissure of the anus, etc.

Dr. Ford thought Van Buren had described a similar condition, but had failed to give the correct explanation of it.

Dr. Bernays mentioned a case of the same kind where the peripheral exciting cause was a varicocele, for on its removal the trouble disappeared.

In the eighth session, in discussing the paper on Care of the Insane, it was conceded that the cottage plan in connection with a main building as headquarters was by all odds the best, and the action of authorities in pursuing the course of filling up buildings of five or six stories, with the idea of economy, was condemned.

Dr. F. J. Gutz presented his paper, which was accepted without being read.

The next meeting will be held at Terre Haute, Ind., some time in September, 1882, day not fixed.

The president for the ensuing year is Dr. J. M. Holloway, of Louisville.

BOSTON SOCIETY FOR MEDICAL SCIENCES.

DR. JAMES J. PUTNAM, SECRETARY.

MARCH 15, 1881. DR. PUTNAM showed two MODIFICATIONS OF THE POND SPHYGMOGRAPH, which will be described elsewhere in detail.

DR. WADSWORTH gave an account of the views held by different observers as to the

CIRCULATION IN THE MACULA LUTEA RETINÆ, and described the evidence afforded by some sections of his own which ran through the fovea centralis. On these sections capillaries could be seen nearer the centre than the point where the dip of the fovea began.

In reply to Dr. C. H. Williams Dr. Wadsworth said he thought the eutoptic test might give a better way of determining the size of the space free from vessels, provided one were certain of the value of the optical constants of the observing eye. It would not, however, necessarily give the relation of this free space to the fovea.

DR. BOWDITCH made a communication on the ARRANGEMENT OF THE PAPILLÆ ON THE ENDS OF THE FINGERS AND TOES,

as shown by impressions on smoked paper. Referring to a recent statement in *Nature*, that such marks are

occasionally found in ancient pottery, and might perhaps be of ethnological interest, Dr. Bowditch spoke of their value for identification during the lifetime of the individual, and illustrated this point by showing impressions from his own forefinger while a medical student in 1865, and again recently in 1881, the two being exactly alike.

He had also tried with about a dozen cases to see how the two sides of the body correspond with each other with regard to the exact arrangement of the papillae on symmetrical parts.

Such a symmetry was found to exist in very many, but by no means in all, cases. It was noticed that instead of being "symmetrical" the markings were sometimes "alike," and in his cases the fingers in which this happened were always the index fingers.

The best method of getting the impressions was either to put printer's ink on the finger or to use smoked paper.

In reply to Dr. Williams Dr. Bowditch said that not only are the fingers of different persons unlike each other but no two fingers of the same person are alike. There are several types of arrangement of the papillae, of which the chief are that of loops and that of whorls.

Dr. CHAS. H. WILLIAMS reported a series of

MEASUREMENTS OF THE BONY PORTION OF THE LACHRYMAL CANAL.

suggested by the statement of Dr. Theobald, of Baltimore,¹ that he was in the habit of using probes up to four mm. in diameter to dilate the lachrymal duct.

Dr. Williams had measured two hundred skulls at the Peabody Museum in Cambridge by using small plugs of wood turned down to the standard French bougie sizes. He had found the average size of the dry, bony canal to be 4.75 mm., that is, very little larger than Theobald's larger probes, but in many instances the canal was much smaller than four mm., showing that often the probes recommended could not be used without crushing the delicate bones forming the lachrymal canal.

Most of the measurements (one hundred and twenty) were made on the skulls of Mound Builders, but these did not differ materially from more recent skulls in this particular.

In two old skulls the passage on one side was occluded, presumably from disease.

Dr. WADSWORTH stated that Dr. Theobald had also made such measurements, and justified his treatment by them.²

APRIL 19, 1881. Mr. MINOT showed a number of

MICROSCOPIC PREPARATIONS

illustrating the Development of the Chick, and described his method of making some of them. It was to float off the object on to the glass slide, at the very outset, retaining it there during the subsequent manipulation by allowing the edges to dry and adhere to the glass.

Dr. JEFFRIES showed a method of detecting false statements in persons assuming not to be color blind.

Dr. PUTNAM related two cases of

FRACTURE OF THE SKULL

that he had seen recently, both of them with rupture of the tympanum and facial paralysis.

Dr. GREEN asked as to the position of the rupture, and the exact nature of the loss of hearing, and spoke of the importance of a careful examination of these points as determining the exact path of the fracture. Dr. Buck's observations were referred to.

MAY 16, 1881. Dr. FITZ reported a case of

ACUTE MILIARY BULBITIS,

occurring at the Massachusetts General Hospital, in the service of Dr. Ellis, of which he had made the autopsy. Sections of the medulla presenting the lesions found were shown under the microscope. The case will be published in the Boston Medical and Surgical Journal at length. The symptoms which preceded the immediately fatal attack of dyspnoea had been but slight, consisting almost exclusively of difficult articulation and thickness of speech, with inability to read fine print, for a week or two. Loss of power in the arms and hands, with numbness and stiffness of the fingers then ensued, and a feeling of general weakness was complained of.

Dr. BOWDITCH made a communication (illustrated), descriptive of some experiments made by Mr. G. Stanley Hall and himself upon the

ILLUSIONS OF MOTION

excited by the movement of cards bearing lines and figures of different shape and position, etc. Dr. Bowditch referred to the observations of Addams, on the apparent movement of rocks behind a waterfall, and rejects as unsatisfactory his explanation that the phenomenon was due to movement of the eyes following the streams of water for a moment and then returning to their starting point. This explanation might suffice for the particular case, but not for others, as, for example, where the apparent movement is spiral. The suggestion also that these illusions are due to an expansion and contraction of the retina appear untenable, and the only conclusion seems to be that they rest on a mental judgment rather than on an actual sensation; that is, that they consist rather in an idea of motion than in a physical sensation of motion.

This is especially well illustrated by one experiment in which, after this feeling of motion has been excited by gazing at a rotating spiral figure, the field of vision is transferred to another surface, such as a blank sheet. It will then be seen that although the whole surface of the sheet seems to expand, the relative position of any two fixed points upon it remains unchanged, showing that the idea of motion which had been excited does not depend for its existence upon an apparent movement of any particular objects in the field of vision.³

Dr. JEFFRIES referred to the report of the committee of the Ophthalmological Society of Great Britain on Color Blindness. They had tested over sixteen thousand persons with results similar to his own. The greater frequency of color-blindness among the Society of Friends, found by this committee, Dr. Jeffries thought might be explained by intermarriage of color-blind families, whilst the sombre garb of the Quakers would not be displeasing to the color-blind eye, and we cannot imagine its constant presence before the eyes as impairing their color-sense in any way.

EXTRACTS FROM A HISTORICAL SKETCH OF
THE OBSTETRICAL SOCIETY OF BOSTON.

BY B. E. COTTING, M. D. (HARV.),

*Member of the Society, etc., etc.**"Historia quoquo modo scripta deletat."*
PLIN. 2dus. V. 8.

THE idea of establishing an Obstetrical Society in Boston originated with Dr. William Read, while he was engaged in writing his monograph on *Placenta Prævia*, an exhaustive treatise, which was published in 1861 by the Massachusetts Medical Society as Vol. XXIII. of its Library of Practical Medicine.

Dr. Read enlisted in the cause his near neighbor, Dr. Charles E. Buckingham, and these two communicated the project to Dr. Charles G. Putnam, who at once readily joined them. At Dr. Putnam's house, in Temple Place, the subject was discussed, and a plan proposed. A circular, without signatures, was sent to such of the profession as were thought to be interested in obstetrical studies, inviting them to meet at the Medical Rooms, 36 Temple Place, to consider and to act upon the matter. A number, thus invited, took no notice of the invitation. If a circular was sent to the writer it failed to reach him. Probably there were others, expected at the meeting, who in like manner never received the notification.

At the meeting, December 7, 1860, there were present, at 36 Temple Place, Drs. Walter Channing, John Homans, Sen., D. Humphreys Storer, Charles G. Putnam, Anson Hooker, Charles E. Buckingham, William Read, John P. Reynolds, Charles D. Homans, Calvin G. Page, Lucius M. Sargent, Alexander D. Sinclair, B. Joy Jeffries, and the writer drawn in as before described.

Drs. George H. Lyman and Zabdiel B. Adams appeared at the second meeting.

Two meetings were occupied in preliminaries, and in adopting a plan of organization, with Constitution and By-Laws. Dr. Charles D. Homans was secretary of these meetings. . . .

In summing up the work accomplished in the first ten years of its existence, we find from its records that almost every *special* topic considered in other States or countries was brought up, for a word at least, before this Society. It is true that we did not have elaborated discussions, with set speeches prepared beforehand, or learned dissertations exhausting subjects under notice, as some foreign societies were favored with. But almost always there was some member present who was able to give the real gist of the matter, or the actual state of existing knowledge, in the questions at issue, — information often quite as satisfactory to the practitioner as that deducible from pretentious discussions like those alluded to.

Nor were the social additions to the meetings without marked beneficial results. They revived and strengthened the Society, and saved it from disorganization. They caused meetings to be fully attended when without them, as had been proved, few if any members would have appeared. Not that any member ever went to a meeting solely for the sake of the entertainment; though there is hardly one who can say that he has not been induced at times to be present because of the invitation, or that he has not made special exertion, more than once, to be in attend-

ance because the meeting was to be held at the house of a particular friend. Of a truth, science, pure and simple, is wonderfully stimulated by the introduction of the social element, as has been notably demonstrated in higher academies, as well as in our unobtrusive special Academy.

As a final and impartial conclusion to this chapter of our history, it may be averred that if, in its first decade, the Obstetrical Society of Boston was not a complete success, professionally and socially, it cannot be called a failure. The opinion of its founders that there was need of it was amply justified. Their hopes were largely fulfilled. Their efforts in its behalf were not unrewarded.

THE SECOND DECADE.

"Vel eadem, vel etiam alias, veras modo."

QUINT. x. 5.

It was not until the introduction of the social element that the survival of the Society seemed probable. But on this addition to its attractions a greater interest was awakened, and it began to prosper. Thenceforward the Society strengthened year by year, and by the end of the first decade had become firmly established. Its meetings were held regularly on the second Saturday evening of each month, except in summer. From the year 1867 to the present time there have been nine meetings every year, with one omission only, that of February, 1875, out of respect to Dr. Putnam, its best friend, then recently deceased. All these meetings were held at the houses of members, who each, as may be truly said, felt a personal disappointment whenever illness or imperative professional duty prevented attendance. The happy combination of the useful with the agreeable, of science with sociality, has done this, and is destined to do much more in the same direction as, in the course of nature, new and better life gradually supplants that passing away. This is the present promise, — one of certain fulfillment, unless discontent with attained good demoralize, or laxness in restrictions be permitted to undermine the Society.

Originally the Society was to consist of twenty-five members only. In 1871 the number was increased to thirty. The election of a candidate likely to prove displeasing to any member was carefully provided against by formalities in nomination, and in the election itself. Two negative ballots, cast unseen in a covered box, were sufficient for rejection. The strictness of these formalities has been remitted somewhat, and the number of negative ballots has been increased to four. But whether these alterations will prove eventually to be beneficial remains to be seen, and is still problematical.

In general those societies thrive best whose portals of admission are most strictly guarded. Societies open to everybody, or of easy entrance, are not held in high esteem even by those who enter; nor is membership in such considered of much honor by the outside world. That numbers may inspire to greater exertions and loftier efforts, that meetings in halls devoted to science only may conduce to worthier labors, restless individuals would fain have their associates believe, not content with quiet progress which perhaps they do little or nothing themselves to stimulate or to promote. Such reformers seem to forget that the amount of "energizing force"² they thus detrimentally waste, if

¹ Written and privately printed for distribution among members of the Society only, at the request of its President.

² Not long ago *force* was the scientific word; recently *energy* obtained; now we have "energizing force." What next?

rightly directed, would obviate the indifference or remove the inertia of which they complain.

That our Society should wholly escape such murmurings was not to be expected; that it has suffered so little therefrom is a matter of real congratulation. There has been from the beginning a repressed inclination in some members to advocate the admission of a greater number than the by-laws allowed. But the social addition, now become essential, putting a limit, though as yet not a rigid one; the necessarily small number who can ever make a specialty of this department; and, more than all, the risk of admitting discordant elements should numbers prevail over proper selection; — these are some of the reasons which have hitherto restrained the conservatives of the Society from permitting changes in its original plan; changes offering uncertain advantages only, while inevitably accompanied with great dangers to the harmony if not the existence of the Society. In fact, however, the rejection of candidates has seldom occurred; and notably there has been a corresponding desire not to press the election of personal friends or acquaintances, if there was found even a chance of disturbing a single member. In this way our Society has avoided dangers and escaped mistakes which have ruined the fair prospects of many a worthy enterprise.

Attendance at meetings has been usually prompt, and reputable in numbers. Members in active obstetric practice cannot ever command a given hour. Temporary absence, illness, and the various haps of life often defeat the best intentions. If there has not been always a large proportion present, the exceptions have been such only as are said to prove a rule.

As a matter of statistics, eight members have died: Channing, Putnam, Hooker, Buckingham, Coale, Page-Palmer, and Sargent; sixteen have resigned member, ship: J. Homans, Sen., Storer, Read, Dupee, Adams, Jeffries, Crane, Damon, Ayer, Shaw, Borland, Lincoln, Treadwell, Oliver, Parks, and Tuck. The present number is twenty-nine. Of the dead, the President has directed suitable notices to be prepared by another and able member. Of the living, long may it be before any pen shall be required to date a completed record.

The Society was formed, and has existed in a period when there seems to have been an increased activity on all sides in subjects connected with its special department. That it kept pace with whatever originated or was held worthy of consideration elsewhere has been already indicated. That of itself it has done something in original work, or newly-tried observations, — enough at least not to be discreditable where the field is so small and the laborers so few, — is susceptible of satisfactory confirmation.

Among matters most frequently discussed that of puerperal fever appears prominent in the Records. Accounts of cases, occurring in numerous instances, singly, in groups, or in series, have been detailed and critically analyzed with convincing evidence that there is such a disease *per se*, distinct from and not induced by simple peritonitis, erysipelas, or other disorders; that while it is usually sporadic, it is occasionally epidemic; that, though sometimes seeming to follow an individual practitioner, conveyance by him is more in appearance than reality; in which respect this disease differs not from other diseases where, when so following an individual, there cannot be the least suspicion of contagion through him.¹

Puerperal convulsions also have occupied much of the Society's attention. That there are various conditions and grades classed under this one term, from the slightest tremor or hysterical agitation to the severest form of apoplexy, is clearly deducible from the Society's Records on this subject. That the presence of albumen, casts, etc., in the urine, and of œdema, general or partial, does not necessarily indicate uræmic poisoning or diseased kidneys — to be followed inevitably by convulsions and a fatal result — is no less certain from the reported experience and observations of members.

Forceps; their history and improvements, their utility, when preferable or not to turning, their judicious but not too frequent use, their application to the pelvic form of the mother rather than to a theoretic place of selection on the child's head — these points have all been frequently under discussion, restraining hasty and confirming deliberate action.

Abortion, justifiable in extreme cases, its proper treatment in prevention or after delivery; these and kindred matters, such as dilatation of the cervix for relief of obstinate vomiting in pregnancy, and the use of chloral in the first stages of labor, have not been neglected.

The number of morbid specimens presented, and of monstrosities of especial interest, has been unexpectedly large, and important points have been illustrated on their dissection.

Milk-leg, so called, local œdema, phlebitis, emboli, pelvic hæmatocele and abscess, erysipelas at or after confinements not communicating itself nor inducing puerperal fever in other parturients, though in adjoining beds, local vulvar erysipelas without internal disturbance, these and other post-partum complications or abnormal appearances have been frequently the subjects of oral or written communications.

Cases of malignant uterine disease, uncomplicated or occurring in the course of pregnancy, have been reported from time to time, giving rise to interesting discussions; so, also, of subinvolution and other embarrassing abnormalities. Dr. Putnam's successful restoration of the organ in cases of long-standing inversion of the uterus, showed wonderful self-reliance in the operator in the adoption of the measures decided upon, and extraordinary dexterity, skill, and long-sustained endurance in carrying them out; and were, moreover, examples of applied science memorable in themselves and notable in the transactions of the Society.

Of the original, as well as most able, communications to the Society were the papers read in February and May, 1878,² by its present president, on The Tonic Spasm of the Internal Os, an intra-uterine annular constriction, tetanic in its firmness and persistence, producing one of the worst forms of dystocia. These papers give an account of his first encounter with this formidable affection, and his original investigations to solve its mysteries, together with his subsequent studies thereon, and the aid he obtained in arriving at a just comprehension of the true clinical condition involved. To these papers the American profes-

18, 1875, pages 323, etc. One member reported five consecutive cases of mammary abscess in his own practice, when there were not any others in the practice of physicians around him. Another practitioner had eight consecutive cases of scarlet fever, in as many different houses, while there were not any other cases in his city. Of course he did not "carry" the disease in these cases, as he was not called to the patients until after it had declared itself.

² Published in the Boston Medical and Surgical Journal, March 21 and May 30, 1878.

¹ See, for example, Boston Medical and Surgical Journal, March

sion¹ are chiefly indebted for their first and full knowledge of what came to the author "with startling impression" as a new and unheard-of experience, and as, in his own words, "an alarming and troublesome novelty."

Sinclair's Method of Introducing Premature Labor, by manual dilatation of the os uteri, is another instance of original work promoted and brought out by this Society. Although he had reported to another society,² several years before, a case in which this method was resorted to, the procedure appears to have failed to make any impression, as the whole discussion which followed digressed entirely to other points in the case; and it did not obtain general recognition until after Dr. Sinclair brought forward his further experience to this Society in October, 1874.³ This new method affords ready, safe, and practical means to control much of the danger and difficulty in cases of convulsions, placenta previa, and accidental hemorrhage.

Uterine measurements post-partum, originating with Dr. W. L. Richardson,⁴ and systematically followed up by him and Dr. Sinclair in their services at the Boston Lying-In Hospital, have afforded interesting original communications to this Society. Among his many other valuable papers, here and elsewhere, Dr. Richardson was the first to call attention of the Society to sub-acute cystitis following pregnancy,⁵ and that produced by tedious or instrumental labor. He also gave us new and practical views on parenchymatous nephritis.

From the foregoing short synopses may be inferred the nature and range of the work accomplished or undertaken by the Society. These synopses do not present the whole, nor even any considerable portion of what has received its attention.⁶ They show, however, personal independence in the observation and study of cases, fearless utterance of opinions formed through practical investigations; and a readiness to submit to the test of discussion and criticism, creditable alike to individual members and the Society. These synopses show also that originality has not been wanting. Still it is not given to every one to make discoveries which shall be accepted everywhere as new and useful. Many things quite valuable in themselves never get into the books or professional traditions, but, if kept alive, must be re-discovered, over and over again, and brought to light with as much real originality in each new as in each preceding instance. Some of the cases cited may be claimed by others at work, at the same or previous times, in the same line of investigations; or something not wholly unlike them may be unearthed by burrowing resurrectionists delving in the dust of long buried records. But such a possibility should not detract in any case from the credit of meritorious activity and public spirit, or honor of originality, of any one, who without mercenary motive unselfishly hastens to communicate his pre-sunable discovery to his associates.

It may be that an eminent foreign professor had already recognized, clinically or in pathological specimens, the peculiar contraction reported to our Society

as a newly demonstrated fact, but that should not render our President, who knew nothing of any such foreign work, any the less an original observer.

It may be that one or another medical man had practiced manual dilatation, in some pressing emergency, but that should not detract from the priority established by a first systematic exposition and publication. The Records of the profession do not appear to show anything of the kind before Dr. Sinclair made known his method.

It may be that post-partum measurements may seem to some an affair of no great moment, but this, if true, which it is not, would not diminish the scientific character of the proceeding, nor abate its merits as an original investigation.

Hence it may be claimed, and not unjustly, that, although it has not had the "inexhaustible stores of obstetric experience"⁷ to draw from, nor "the prodigious advantages afforded by an enormous population,"⁷ which the Obstetrical Society of London may exult in, our small Society, in its narrow opportunities and with its limited number of workers, has not been unmindful of its obligations to science. In this regard it has not hid its one talent in the earth.

But after all our Society was not founded solely, nor even in a secondary degree, with a view to original discoveries. Its founders had in mind mutual improvement in a particular department of medicine,—the better understanding and the better performance of the every-day routine-work of the individual practitioner,—and all that renders that work safe, quick, and successful to both the patient and the attendant. Common cases, common experiences, common practice, frankly related and freely discussed for the benefit and further re-assurance of all; these were held of first importance. The extraordinary and the terrific would of themselves force recognition. Original investigations would follow as a matter of course. Discoveries would from time to time reward the painstaking searcher into the secrets of nature. These, and such as these, were the objects, hopes, and expectations of the original founders of the Society.

This, then, is the simple and unvarnished story of our Society, as it appears to one observant of its origin, its methods, and its progress since its foundation. It has survived the dangers of infancy, and the complaints of childhood. Its commencing adult age is one of confidence and promise. Unnoised advancement, *viresque acquirit eundo*, is its present encouraging characteristic. Admission into its circle is now sought for; and is becoming, more and more, an object of ambition with those interested in obstetrical studies. It offers advantages of inestimable value to members more especially engaged in practice in this department of medicine.⁸

—According to the *British Medical Journal*, recent numbers of the Russian medical journal, *Tratchebniya Vedomosti*, contain translations of Professor Lister's address on the Cat-gut Ligature, delivered before the Clinical Society; of Dr. J. S. Billings's address on Modern Medical Literature, delivered before the International Medical Congress; and of M. Pasteur's address on Vaccination in Relation to Chicken-Cholera and Splenic Fever.

Medical and Surgical Journal.

THURSDAY, NOVEMBER 17, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

INSANE ASYLUM MANAGEMENT AND CONSTRUCTION.

SIXTH BIENNIAL REPORT OF THE BOARD OF STATE COMMISSIONERS OF PUBLIC CHARITIES OF ILLINOIS.¹

THE Report referred to in our heading contains many good things concerning the charities of Illinois. In this review, however, we shall bring forward only those portions regarding the subject of insanity, as they possess great interest at this time. The writer, though it is to be assumed that he is not a medical man, sees far below the surface, and grapples with problems which have hitherto been a snare and pitfall, in a highly original and common-sense manner.

Concerning the subject of pathological work in insane hospitals, the Report says, "We hardly know how to treat the request for one thousand dollars for apparatus for a pathological laboratory without seeming, on the one hand, to discourage investigations of whose scientific value we are fully aware, or, on the other hand, without leading the State to expend money to no purpose and cherish expectations which ultimately may be disappointed." The writer proceeds to say that the duties of the officers of an insane hospital are so arduous that they do not have the time for pathological work. The work could only be properly done by special pathologists, and if one hospital has one, others, to be on an equal footing, should have them also. "There is no department of medicine which requires such special faculties, such special knowledge, and such special training as this. Whether a young man of average ability can ever overtake the masters of this branch of medical research is doubtful. . . . But if we understand the subject at all, the special purpose of this microscopical research is to determine the truth or falsity of the modern theory of the localization of central function. Publications, therefore, which do not address themselves directly and pointedly to the solution of this question and carry the investigation to a point beyond any to which it has already been pushed, are of comparatively little value. Instead of confining their delicate research to a novice in his profession, part of whose time is taken up with the visitation of the insane wards of a hospital and the other subordinate duties, incident to his subordinate position, we should very much prefer that, should the State deem it advisable to undertake the pathological investigation, of the propriety of which we have not the slightest doubt,

it should employ a man of commanding ability . . . who should give his whole time to this exclusive work."

It would be better, undoubtedly, in the interest of pure science to have a special pathologist in each hospital, but we very much doubt if the men of "commanding ability" can be got to do the work. We can hardly hope to gain the great results spoken of in any of our American insane hospitals at present. We cannot even expect to verify the discoveries already made by European investigators. The whole standard of American medical education must be considerably raised before the staffs of insane hospitals will have the knowledge to do very simple pathological work. Every year, however, sees progress, every year better educated men enter insane hospitals. In a small State like Massachusetts we think now that a State pathologist might be appointed. He would be an organizer of work in his department, — the founder and teacher of a system. By and by, when the hospital staffs were large enough and when they were educated up to the work, they might be safely left to stand on their own feet.

We do not agree with the writer that pathological work would be comparatively useless unless it added to the existing stock of information on the subject. Such work is not usually undertaken to determine the truth or falsity of cerebral localization, but rather to aid the physician in his study of the case in hand. Each hospital physician should, in a perfect state of things, be able to use the microscope to clear up symptoms, define accurately probable changes during life, and thus gradually learn how to better manage similar cases. In this way he adds to his own knowledge, and in every way helps himself in his practical understanding of disease. He must use the microscope more than others, because the organ which he studies betrays its disease in many cases only by its use. He cannot, does not expect, in fact, to make discoveries for the world. When, however, the use of the microscope is general, occasionally a genius will be found who will, from his own transcendent abilities, make investigations which will carry science further on than it was before.

The description of the new Eastern Insane Hospital at Kankakee, now under the superintendence of Dr. Richard Dewey, is extremely interesting, not only from the originality of arrangement of the buildings, but also as it is highly probable that Massachusetts may soon be called upon to take steps toward the erection of a hospital within her borders.

The plan of the hospital embraces as its central feature a building constructed very much after the plan of the ordinary insane hospital. There will be the same "centre building," on a much smaller scale, however, than is usual, for a few officers. To this will be attached wings, one for either sex, each accommodating one hundred and fifty patients. The rear buildings also conform to existing models.

At this point begins the new departure. The wings cannot be extended further as the roadways will prevent. "Two broad avenues, parallel with a line, at right angles to the line of the wings, present

¹ Presented to the Governor November, 1880.

the appearance of village streets, bordered with sidewalks, and shaded by elms and maples. On each side of these two streets the land is laid off in lots for building purposes, and the original plan contemplates the separation of each lot by a simple fence, with a gate in front communicating with the street. . . . Each lot is to be occupied, as occasion may require, by a detached ward for insane patients, or by any other building, for instance, by a private residence for an assistant physician,"—assistant physicians will at once apply in a body for positions at Kankakee,— "or by a work-shop or general bath-house." The buildings, thus far, are of wood, but may be of other material. The appearance of these detached wards is like an English asylum, except the wards of the latter are connected by corridors. "A marked difference between these wards and those of any other institution on either side of the Atlantic consists in their being built each after a different pattern, both as to exterior aspect and the internal arrangement. No two are alike. To a certain extent they resemble the French asylum wards in this, that they are all two stories in height, and are so planned as to provide in some form day rooms upon the lower floor and dormitories above. But the proportion of single dormitories is smaller than that usually found in American hospitals for the insane. These buildings are designed to be the homes of a class of chronic insane who either have no homes of their own, or who, for special reasons, cannot live at home. The patients residing in them will sleep, for the most part, in large associated dormitories under the eye of their attendants, and herein lies the great secret of cheap construction." Each of these buildings will contain twenty-five to thirty inmates, and be a detached ward rather than a "cottage."

In the organization of this hospital an effort is made to solve the question of how the management can be made most effective. Generally persons living outside of insane hospitals say that superintendents do not give enough attention to their medical duties and too much to business details, and are of opinion that the latter should be left entirely to a business head. At Kankakee they recognize the difficulties, but deal with them in an original manner. The Report says that the plan "contemplates a more complete separation between the medical and business control of the establishment. Not that it is designed to have two heads and a divided responsibility, nor is the officer in charge to be a non-medical man, but, in reality, whatever may be the amount of individual attention paid to certain patients by a medical superintendent, and however familiar he may be, not only with the general physical and mental condition of his patients, but with the capacity of his medical assistants and their treatment of individual cases, we think that it remains true that his time is and must be principally taken up with details and administration. . . . It is important for all parties that the superintendent should be known as the business manager; and that his first assistant should be known to be in fact the principal medical officer, notwithstanding his responsibility for his medical practice to his chief. By taking the business offices out of the hospital proper, by giving to the superintendent a

private residence outside of the centre building, by placing the first assistant in the centre building, in proximity to the patients and freeing him from all connection with the business management, so that he can give his individual care to the patients, and, above all, by paying him an adequate salary, enabling the institution to command the very best medical talent, and notifying the public of the estimation in which he is held, this important end can be attained." This plan of organization and the plain, bold way in which it is advocated deserves careful consideration, for it offers a way out of a perplexing situation. We ourselves are most anxious to see the highest standard of scientific attainment arrived at in the management of insane hospitals, and would much prefer, theoretically, that medical superintendents should devote all their time to medical duties, but when, practically, we see an insane hospital managed by a non-medical man, we see at once a falling off in the high character of care and treatment furnished the patients. As a matter of experience we should say that only medically-educated men could be expected to fully understand at their full worth the very varied and peculiar necessities of the insane.

On the subject of restraint the following very sensible remarks are made among others: "Nor is it necessary to advocate any extreme and foolish doctrine on the subject of restraint, such as its entire abolition, or even the abolition of mechanical restraints by making a *bond-fire* of crib-beds, camisoles, and leather muffs. All we claim is that any man, sane or insane, should not be deprived of any part of his liberty any further than is required for his own good, or the safety and comfort of others; and that the monotonous uniformity, both of architectural plan and of internal discipline, which characterizes many, if not all, insane asylums in the United States, does tend to deprivation of their liberty by compelling the application of prohibitions to the vast majority of patients which with many are useless and with some positively injurious. . . . We do not pretend to say what proportion of patients are suited for a freer life in detached wards; nor what is the best form for such wards. . . . If it is said a superintendent cannot know whom to trust, we reply that it is his business to know, and that he can only ascertain this by trial."

As bearing on the subject of provision for insane criminals, it is interesting to know that an asylum for *insane convicts* is about being built in connection with the State Prison at Chester. Of insane convicts there are, in the insane hospitals and prisons of Illinois, at present, seventy-eight. The Report before us recommends that the *unconvicted* insane criminals should be sent to this asylum, as well as the insane prison convicts. No one longer doubts that insane criminals should be removed from our insane hospitals, and as the numbers of the convicted and unconvicted are, as yet, not large enough to warrant separate hospitals, it would seem most expedient to place them together.

We see several objections to the building of a criminal asylum on the grounds of a prison. These are the following: (1.) The entire change of life and surrounding, so important in the treatment of insanity,

would not be attainable for the convicts from the prison. (2.) Intercourse with the prison officials and among the sane and insane convicts would be almost unavoidable, thus keeping up the pernicious prison influence. (3.) The discipline of the asylum would be more rigid than necessary at a greater distance from the prison, and probably would be modeled after the prison. Very probably, too, this would be promoted by keepers transformed into attendants. (4.) A sufficient area of farming land, we should suppose, could not be furnished within the prison walls. A good-sized farm would be required for one hundred insane criminals. (5.) The food, which would probably be largely cooked within the prison and furnished from its stores, would not be the proper fare for a large proportion of the criminal insane, who are often anæmic and dyspeptic, and require more nourishing food than the ordinary hardy convict. (6.) Such an insane department of the prison would have more or less of the disgrace attached to it belonging to the prison, and it would, therefore, be difficult to get the consent of the friends of the unconvicted insane to place them in it.

Such an insane department may be better than nothing, but, in our opinion, the wisdom of creating it would depend on the number of criminals needing this separate treatment. Twenty insane men from the prison would perhaps do well in the corner of a large yard, walled off by themselves with five or six acres of land to till, but if a building for one hundred is to be built, we hold that a building remote from the prison, with fifty to one hundred acres, under proper medical supervision, will in the end be as cheap, and will do far more to relieve the insane hospitals, the prisons, and the public of the troublesome class of insane criminals than any kind of building within the prison walls, to say nothing of the greater chance of recovery under these more favorable circumstances.

A GOOD CAUSE AND AN IMPULSIVE FRIEND. THE INDEX MEDICUS.

WE were sorry to read an editorial in the last number of the *Philadelphia Medical Times* on the duty of supporting the *Index Medicus*, which seemed to us to be conceived in poor judgment and composed with poor taste. As an example of what we mean, and by request of the editor, we quote the following passage, not being able to copy the whole:—

"As Philadelphians we are proud that three of our local societies—the Philadelphia County Medical Society, the Philadelphia Pathological Society, and the Philadelphia Obstetrical Society—subscribed each fifty dollars to keep alive last year this great bibliographical magazine. As Americans we are ashamed that in the whole length and breadth of this land not one State or local medical society outside of this city was found to follow the example set. It is no less surprising than depressing that with associate intelligence they have all stood by and seen the great work tottering to its fall. New York, boasting continually of its greatness, its progress, and its wealth,—New York, where the *Index* is published, where so many of the profession dwell in palaces, are clothed in purple and fine linen, and fare sumptuously every day, has done nothing. Boston,—in its own conceit the Athens of America,—with its perpetual smile of self-congratulation, its lips dripping with the honey of self-congratulation, has done less. Philadelphia has done no more, in its rush and greed for material wealth. St. Louis, Cincinnati, Baltimore,

New Orleans, San Francisco, Pittsburg, Albany, and our innumerable smaller cities,—where are they? An annual subscription of twenty dollars from each of the societies of these cities would enable Mr. Leypoldt to continue the publication of the *Index*. Will they not give it?"

Now if one really has the welfare of the *Index Medicus* at heart this is not the best way to further it. What the *Index Medicus* requires is support, and the cordial coöperation of its friends is needed to procure the same. The exact form of the support is of less immediate consequence. We venture to say that if the *Medical Times* will take the trouble to inform itself it will find that in the amount of support given the *Index Medicus* Philadelphia occupies neither the first nor the second place, but that New York and Boston, respectively, do. We happen to know that one individual physician in Boston this year contributed half the sum named as the amount subscribed by the Philadelphia County and the other Philadelphia medical societies.

What has been done, however, is no good reason for not doing more, and we are glad to say that one Boston Society, that for Medical Improvement, has voted to contribute fifty dollars to the *Index* the coming year. It is undoubtedly an excellent opportunity for friendly emulation, only let us all be pleasant about it, and if it so happen that there are any ancient grudges which must be fed fat let it not be at the expense of the *Index Medicus*. We hope Boston medical societies will bestir themselves, that individual enthusiasts will multiply in Philadelphia, and that Chicago will have the grace to surpass both places in both forms of support.

DR. O. W. HOLMES' BOYLSTON PRIZE ESSAY ON INTERMITTENT FEVER.

THOSE who by reason of its reappearance may now feel an awakened interest in intermittent fever, as it formerly exhibited itself in New England, would do well to consult Dr. O. W. Holmes' Boylston Prize Essay, written in 1836, entitled *Facts and Traditions, Respecting the Existence of Indigenous Intermittent Fever in New England*. Dr. Holmes' very complete and instructive historical essay is freely quoted from in Dr. Adams' paper on Intermittent Fever, published in the recent report of the Health Department of the Massachusetts Board of Health, Lunacy, and Charity.

MEDICAL NOTES.

—The Boston Board of Health has recently inspected the Cochituate and Sudbury Rivers systems in company with a member of the Water Board. This latter board seems disposed to hold Farm Pond, and it alone, responsible for the present wretched condition of the Boston water. It may not be loam at the bottom of the Sudbury River Basin and it certainly is not cels. The Board of Health assures inquirers that the health of Boston was never better, and if it is a consolation to its inhabitants to know that they can not only drink such abominable stuff as is now supplied them, but thrive thereon, they had best make the most of it.

— One death was reported in Providence from malarial fever during the month of October.

— On Saturday last there were in hospital three cases of small-pox and no further cases were known to the Board of Health. One case has recently shown itself in western Massachusetts in a young man who went home sick from this city.

— Dr. H. O. Marcy addressed the Society of Arts of the Massachusetts Institute of Technology on Some Factors in the Sanitary Condition of Boston, on Thursday last.

— In last week's note of changes in instructors at Harvard Medical School, Dr. E. H. Bradford was noted as assistant in clinical surgery. He is also to give special instruction in orthopaedics.

Miscellany.

PRACTICAL DEDUCTIONS DRAWN FROM ONE THOUSAND DIGITAL EXAMINATIONS OF THE PHARYNGEAL ORIFICE OF THE EUSTACHIAN TUBE AND FOSSA ROSENMÜLLER.

BY H. H. WYNNE, M. D.

IN the study of pathological conditions of the organ of Audition, of the aetiological relation to disease of the throat being of so intimate a character, it is to be regretted that an anatomical distinction, or a separation between the cavity of the ear and that portion known as the nasopharynx, should at all be attempted by anatomists. This portion, the nasopharynx, is no less a part of the ear pathologically than is the middle ear itself; seventy-five per cent. (Heuson) to ninety per cent. (Mittendorf) of ear disease finding its cause in disease of the pharynx, of which the nasal part is here important.

It has been well said that the nasopharynx, pathologically, and therapeutically, is of greater importance than the drum cavity itself to the organs of hearing as a whole. Why? With a closure of the Eustachian tube at its pharyngeal orifice referable to disease of this part, we have a deafness that yields only to the re-establishment of the patency of these openings. Again, the middle ear may be deprived of one of its walls, the tympanum, lose its contained ossicles, even suppurate for a long time, and yet retain a certain and valuable degree of its function. This rehearsal of acknowledged facts sufficiently recalls to the mind the pathological importance of the nasopharynx to cause it to be considered, for other than anatomical reasons, as a part of the ear.

The nasopharynx, therapeutically, is the most important part of the ear.

What is understood by the nasopharynx is all that part of the pharynx above the level of the soft palate. Opening anteriorly are the important orifices known as the posterior nares, and partly in the cavity of the nasopharynx we have the orifice of the tube that forms the connection between these cavities and that of the tympanum. The orifice and tube being lined by the membrane common to the pharynx and nose, and participating directly and indirectly in the inflammatory affections common to this mucous lining. Of all the secreting surfaces of the cavities of the body this is the one that is most frequently found to be the seat of dis-

ease; the inflammatory action passing directly through the tube and involving the tympanic cavity, hence the aetiological origin of the seventy-five per cent. to ninety per cent. of ear disease.

The pharyngeal orifice of the tube, and fossa Rosenmüller lying immediately posterior, are the parts to be examined. The cavity containing these anatomical parts admits of inspection by methods direct and indirect. Direct, when the patient has a large mouth and wide facial opening, which is not at all infrequent; then by rotating the inferior maxilla to the side opposite to the orifice of the tube to be examined, at the same time depressing its angle, the orifice of the opposite Eustachian tube often lies in a direct line and can easily be seen together with the posterior depression known as the fossa Rosenmüller. This procedure is aptly shown in the work of Professor J. Solis Cohen, a case of cleft palate affording the extensive view there presented. The method by the use of the rhinoscope constituting the indirect one need not now be further mentioned.

It is, therefore, to present the claim for the support of a method that is rapid, easy of execution, and one that does not necessitate the use of scientific instruments, that I write this article, to present my views on a subject of importance to the profession, and they are submitted for all they may be found to be practically worth. The method to be proposed has no element of novelty, introduces nothing new to overburden the methods already in use for diagnosis in this region of the respiratory passages. The method is one of simple digital examination. The fact of its not being made routine practice in our large throat hospitals is to be regretted, as it never fails to provide for the most serious emergencies of practice. Its origin, history, etc., I am unable, from suitable reference, to discuss. I consider this method to be entitled to higher rank than those constituting routine practice in the private office and hospital clinical service. To the general profession this method commends itself most highly and does not necessitate a loss of time and the so-called scientific use of paraphernalia. This method is not new, and is only going a step further in parts to be examined, than the region so frequently explored digitally by the dental profession.

While a student in the large general and special hospitals of New York, I have had ample opportunity to practice this method of examination, and I am now as independent of the use of the rhinoscope as I am dependent upon the use of my laryngoscopic mirrors in the examination of the larynx. By its use I can immediately determine the normal or pathological condition of parts within reach of the finger, namely, the pharyngeal orifice of the Eustachian tube, the posterior fossa of Rosenmüller, Luschka's tonsil, occupying a central position in the posterior wall of the pharynx, and terminating laterally in this fossa, the posterior nares immediately in front, and here by the digital examination I am able to diagnose the existence of polypi and hypertrophy of the membranous covering of the inferior turbinated bones. A most important point gained by the method is the *direction* of the Eustachian tube at its pharyngeal extremity, and the existence of delicate contracting bands in the fossa of Rosenmüller.

Professors Cohen and MacKenzie mention the existence of these bands, but they are more numerous than the writers would lead an inexperienced operator to

suppose. Whenever in a new case I find it difficult to pass my Eustachian catheter, I immediately make a digital examination, and I find many times the difficulty lying in the mis-directed orifice, this being drawn backward by contraction of bands or by contraction of the membrane itself lining the fossa posterior to the orifice, as is frequent in the condition known as pharyngitis sicca. Many times, by rupture of these bands, I have succeeded in guiding the curved end of my Eustachian catheter by the finger passed up and behind the soft palate into an otherwise practically closed tube, inflated the ear by the bag, and sufficiently increased the hearing to warrant the successful treatment of a case which I could not otherwise have undertaken. The pathology of the fossa of Rosenmüller offers an inviting field of study.

I shall never regret having commenced early the practice of this method of pharyngeal examination, having first had my attention directed to it by a fellow-student of disease of the throat at the Bellevue Hospital, who had practiced it in three thousand cases at the age of twenty-three years, and who was most rapid in his examinations, and equally definite as to the condition present in any given case. It may not be improper to state that this young man was blind, and that he had acquired a proficiency by touch that excelled in rapidity, correctness, and minuteness of detail the use of our complicated instruments and much-valued eyesight.

The method of digital examination consists in passing the index finger of the right hand, when the right tube orifice is to be examined, into the mouth, up and behind the soft palate to the orifice, which can easily be distinguished by its slight depression, the operator standing upon the right side of the patient. In examining the left tube the order is reversed. The time of the examination varies from half a minute to three minutes, and disease of any of the structures that can be examined is immediately determined. This method can be used in cases where, by complication, the use of the rhinoscopic mirror is either unsatisfactory or impossible.

I think that in the future the digital method of rapid examination will become one of routine practice in diagnosis of diseases of these parts, and that the close aural relation of the naso-pharynx will become a more generally recognized element among the profession in the study of pathology and therapeutics of ear disease.

JONESTOWN, PENNA., October, 1881.

NON-VENEREAL SYPHILIS.

MR. EDITOR.—I wish to record the following case as evidence of the entire possibility of a perfectly healthy individual becoming infected with constitutional syphilis from using the same drinking-glass with a person having constitutional syphilis even in its later forms.

B., a young American, enlists in the navy at Charlestown, Mass., and is assigned for duty as a servant to one C., whose nose is depressed, and whose throat and shin-bone are plainly diseased,—syphilis. All in the yard well know of the nature of C.'s malady, and family troubles on that account had previously occurred. After serving a short time, some four weeks or six, B. notices "his own mouth to be sore, with a punched-

out, yellowish-looking spot on his lip, followed shortly by other sores on other parts of his mouth and tongue," as he describes it. On application to the surgeon he is told that he has a canker spot, and it is burned with lunar caustic; later the truth is told him, and mercury ordered, and in June last he is discharged, having well-marked mucous patches and enlarged glands of whole neck, nasal and laryngeal catarrh.

At the Boston Dispensary, on August 22d, he was seen by the writer together with Dr. Bush and others, and he then presented all of the above-named constitutional signs of syphilis. No marks of former disease, no trace of history of other cause could be obtained other than that B. drank from the same tumbler at the ice-pitcher as did C. often. No pipe was ever used by either, cigarettes alone. The boy was healthy, twenty years old, when he passed the examination, and was enlisted in the service six or eight weeks prior to his presenting the first-seen sore mouth. Since discharge he has been married, and his wife now has some throat trouble and enlarged glands of the neck. (No examination as yet has been obtained of her, however.)

As every pains were taken to exclude sources of error in the case, it has been thought to be, perhaps, of sufficient value to present these brief facts for publication.

JOHN DIXWELL, M. D.

LONDON SANITARY PROTECTION.

At the first general meeting of the London Sanitary Protection Association, after an account of certain financial details had been given by the treasurer (Mr. Holmes), Prof. Fleeming Jenkin said that the cost was small, the importance great, and already many similar institutions had been established all over the country. Inspections had been made of one hundred and eight houses, and of these seven were found to be entirely without drainage, the drains having become completely choked. In several instances no suspicion existed of this state of things, for the sewage was making its way into the soil under the houses. In thirty-three houses the drains were found not to be gas-tight, and allowed the sewage-gas to go into the houses. This was discovered in a very simple way, namely, by pouring a little oil of peppermint into the sewer, from which the smell rose into the house. In twenty-seven cases the overflow-pipes from cisterns were connected with the drains. Professor Huxley said that when they came to congregate three or four millions of people on a surface of fifty square miles, if care were not taken they would be decimated, not as in the old days, by the black death, but by other diseases which were readily disseminated by the system of water drainage if it were imperfect. The old cesspool was, he thought, far less dangerous than an imperfect system of water drainage, which was a perfect machinery for disseminating disease, while the water drainage if in perfect order was the best that could be. Therefore the question was, how were we to see that this water-sewage system was maintained in a reasonably perfect condition. A government inspection he did not think would be tolerated by householders, and it would be most expensive. The best mode was that of a regular sanitary inspection by our own engineers, and this was what the Association offered at a cheap rate. He hoped it would become extensive and useful.—*Medical Times and Gazette*.

Deaths reported 2773 (no report from Buffalo); 1018 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 752, consumption 407, lung diseases 281, diphtheria and croup 247, diarrhoeal diseases 166, typhoid fever 123, malarial fevers 64, small-pox 55, scarlet fever 53, whooping-cough 19, cerebro-spinal meningitis 10, erysipelas six, measles four, puerperal fever four, typhus fever one. From *malarial fevers*, St. Louis 13, New York 12, Brooklyn 10, New Orleans eight, Philadelphia six, Baltimore and District of Columbia four, Chicago three, Nashville two, New Haven and Charleston one. From *small-pox*, Pittsburgh 24, Philadelphia 13, Chicago eight, New York seven, Brooklyn, Baltimore, and Gloucester one. From *scarlet fever*, New York 23, Brooklyn 10, Philadelphia six, St. Louis and Pittsburgh three, Cincinnati two, Chicago, Milwaukee, Worcester, Fall River, Lynn, and New Bedford one. From *whooping-cough*, New York six, Brooklyn four, Chicago three, Baltimore two, Philadelphia, Boston, St. Louis, and Pittsburgh one. From *cerebro-spinal meningitis*, New York six, Brooklyn, Boston, Worcester, and Chelsea one. From *erysipelas*, New York and Pittsburgh two, Baltimore and Salem one. From *measles*, Chicago and Pittsburgh two. From *puerperal fever*, New York, Chicago, Boston, and Haverhill one. From *typhus fever*, Chicago one.

Two cases of small-pox were reported in Brooklyn, three in Boston, four in St. Louis, two in Baltimore, five in Cincinnati, 52 in Pittsburgh; typhoid fever 34, diphtheria 29, scarlet fever two, in Boston; diphtheria five, scarlet fever four, in Milwaukee; typhoid fever 20 in Cambridge.

In 38 cities and towns of Massachusetts, with a population of 1,039,737 (population of the State 1,783,086), the total death-rate

for the week was 20.16 against 19.64 and 21.29 for the previous two weeks.

For the week ending October 15th in 149 German cities and towns, with an estimated population of 7,936,736, the death-rate was 22.9. Deaths reported 3499; under five 1576: pulmonary consumption 453, acute diseases of the respiratory organs 300, diphtheria and croup 153, diarrhoeal diseases 136, scarlet fever 111, whooping-cough 70, typhoid fever 51, puerperal fever 23, measles and r6theln 17, typhus fever (Thorn, Erfurt, Bremen) three, small-pox (Aachen) one. The death-rates ranged from 14.5 in Halle to 31.4 in Posen; K6nigs-berg 28.8; Breslau 27.7; Munich 30.5; Dresden 14.4; Berlin 22.7; Leipzig 21.3; Hamburg 21.7; Hannover 17.8; Bremen 21; Cologne 24.1; Frankfurt 21.2; Strassburg 23.6.

For the week ending October 22d in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 21.2. Deaths reported 3097: acute diseases of the respiratory organs (London) 319, scarlet fever 138, fever 102, measles 74, whooping-cough 61, diarrhoea 57, diphtheria 31, small-pox (London) 14. The death-rates ranged from 15.6 in Bristol to 29.9 in Hull; Birmingham 16.2; Leeds 16.6; Sheffield 20.1; Manchester 20.6; London 21.6; Liverpool 28.9. In Edinburgh 23.5; Glasgow 22.6.

For the week ending October 15th in the 21 chief towns of Switzerland, population 479,934, there were 29 deaths from pulmonary consumption, acute diseases of respiratory organs 21, diarrhoeal diseases 19, diphtheria and croup 13, typhoid fever three, whooping-cough and measles each one. The death-rates were, Geneva 20.5; Zurich 21.7; Basle 19.3; Berne 29.3.

The meteorological record for the week ending November 5th, in Boston, was as follows:—

PRIZE-REWARDS OFFERED BY THE DANISH SOCIETY FOR PROTECTION OF ANIMALS.

The Danish Society for Protection of Animals (under patronage of His Majesty, the King of Denmark) offers two prizes, of 2000 and 1000 francs respectively, for the best and second best scientific essay on that part of the vivisection question which concerns the possibility of replacing *living* by *recently-killed animals* during physiological investigations, and sufficiently indicates not before known cases, in which such a substitution of dead material may be applicable.

It refers specially to a well-known declaration of Professor M. Schiff, that "under certain circumstances the functions of life may be studied in recently-killed animals."

In these essays the possibility and desirability of replacing painful experiments on animals by some other methods of research may also be a subject of inquiry.

The essays may be written in the Danish, Swedish, English, French, or German language; they must be clearly and legibly written, signed with a motto, which is also to be placed on an accompanying sealed envelope, containing the name and address of the writer. These are to be forwarded before the 1st of September, 1882, to His Excellency, Mr. A. de Haxthausen, President of the Danish Society for Protection of Animals, at the office of the Society, Copenhagen.

The board of directors will secure scientific assistance in awarding the prizes; in the event of none of the essays possessing sufficient merit to warrant a prize, smaller rewards will be given to those competitors whose essays bear evidence of ability as well as sympathy with the objects of the Society, which reserves all rights of publication.

The Society expresses itself as only too well aware that the claims of humanity are not to be satisfied by these means as extensively as it should wish. It will, however, feel itself richly rewarded if its efforts result in diminishing the number of experiments in which animals are subjected to great and lingering agony. In this earnest hope it respectfully requests all humanely feeling scientists of every country in the world kindly to comply with its challenge.

OBITUARY.

Dr. ALSTON W. WHITNEY died at his residence in West Newton, November 11th, at the age of about fifty years. He practiced his profession for a short time in Boston, and at the opening of the war of the rebellion he entered the service as surgeon of the thirteenth Massachusetts regiment, and was afterward promoted to brigade surgeon, with the rank of lieutenant colonel. He was taken prisoner and sent to Libby Prison, where he was confined six months before being exchanged. While in Libby he, with several other officers, also prisoners, was ordered to be shot, in retaliation for several rebels executed by the Federals, but he was saved by the decisive action of General Butler, who notified the rebel authorities that if the men were shot he would immediately shoot two rebel generals held as prisoners by him. At the close of the war Dr. Whitney located in Newton, where he has remained ever since, and his death will be felt by a large circle of friends.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM NOVEMBER 5, 1881, TO NOVEMBER 11, 1881.

KING, WILLIAM S., colonel and surgeon. The extension of leave of absence on account of sickness, granted him in S. O. 105, May 7, 1881, from A. G. O., still further extended six months on account of sickness. S. O. 251, A. G. O., November 7, 1881.

McCLELLAN, ELY, major and surgeon. Now awaiting orders at Louisville, Ky., to report in person to the commanding general, Department of the East, for assignment to duty. S. O. 252, A. G. O., November 8, 1881.

HARTSUFF, ALBERT, major and surgeon. The leave of absence granted him in S. O. 214, October 20, 1881, Department of the Missouri, is extended nine months, with permission to go beyond sea. S. O. 251, A. G. O., November 7, 1881.

MEACHAM, F., captain and assistant surgeon. To accompany from Fort Trumbull, Conn., to the Military Division of the Pacific, Batteries C and M, First Artillery, ordered to start on 11th inst. Upon completion of this duty to rejoin proper station in Department of the East. S. O. 66, Military Division of the Atlantic, November 8, 1881.

FINLEY, J. A., captain and assistant surgeon. To accompany from Fort Adams, R. I., to the Military Division of the Pacific, Light Battery K and Batteries B and E, First Artillery, ordered to start on 14th inst. Upon completion of this duty to rejoin proper station in Department of the East. S. O. 66, C. S., Military Division of the Atlantic.

TERRILL, H. S., captain and assistant surgeon. To accompany Battery H, Third Artillery, from Madison Barracks to New York city, and on arrival report in person at these headquarters for further orders. S. O. 67, Military Division of the Atlantic, November 9, 1881.

HALL, W. R., captain and assistant surgeon. Granted leave of absence for one month. S. O. 224, Department of the Missouri, November 2, 1881.

The following-named medical officers will report in person, without delay, to the commanding general, Military Division of the Atlantic, for temporary duty with regiments about to change stations. Upon completion of their duty with these regiments to report by letter to the Surgeon General: First Lieutenant E. C. CARTER, assistant surgeon; First Lieutenant H. I. RAYMOND, assistant surgeon; First Lieutenant T. J. C. Maddox, assistant surgeon. S. O. 248, A. G. O., November 3, 1881.

RAYMOND, H. I., first lieutenant and assistant surgeon. To accompany Batteries A and D, First Artillery, from Fort Columbus, New York Harbor, on 10th inst., for San Francisco. S. O. 66, C. S., Military Division of the Atlantic.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held on Monday evening next, at eight o'clock, in the hall of the Medical Library Association, 19 Boylston Place. Reader, Dr. Knight. Subject, The Treatment of Posterior Hypertrophy of the Tubulated B. nes. M. H. RICHARDSON, M. D., Secretary.

Original Articles.

CASE OF PYEMIA OF OBSCURE ORIGIN.¹

BY FRANCIS MINOT, M. D.

THE unusual duration of the following case renders it impossible for me to report it, on the present occasion, in all its details. I shall, therefore, confine myself to the most prominent points, taken from the daily record, trusting that nothing essential will have been omitted.

The patient was a married lady, forty-seven years and nine months old, the mother of four children. She was of a nervous temperament, and had formerly been subject to attacks of hysteria, and possessed unusual intellectual endowments. Although somewhat delicate in general health, she had never had any special febrile or constitutional disease since childhood. Her menstruation was regular. She passed the summer of 1880 at the seashore, as usual. While there she had a succession of boils in various parts of the body, without any other manifestations of sickness, and shortly before the beginning of her last illness was in her usual health. She occupied the same house during the summer as in several previous seasons, and there was no other case of sickness in the family. On September 23d, shortly after her return to Boston, she went to Newport, R. I., where she passed two nights and one day in a house which was quite isolated, and in which there neither had been, nor has been since, any sickness.

A few days after her return from Newport she began to complain of pain in every part of the body, and of inability to sleep. At my first visit, October 2d (the sixth day of the disease), the pulse was at 100; tongue much coated; bowels regular; there was no appetite. In the course of a few days she had some hysterical symptoms, occasional sobbing, a feeling described as faintness, but without the objective symptoms of syncope. There were no symptoms of typhoid fever. The first and second joints of the right little finger were red, swollen, and painful. There was also pain and tenderness, but no redness, in the calf of the left leg. She complained of wakefulness and of loss of appetite. The menstruation appeared at the regular time, October 4th (eighth day), and, except that it was rather less abundant than usual, was normal. It did not recur afterwards. For the next few days her condition varied but little. She was despondent, and did not wish to recover. On the sixteenth day (October 12th) a small painful swelling was observed at the base of the little toe of the right foot, on the plantar surface, the finger meanwhile having become well. The swelling increased, fluctuation appeared, and on the twentieth day it was incised, and a free discharge of pus took place. The patient now began to complain of pain and distress in the abdomen, and this symptom was prominent throughout the remaining course of the case, but repeated careful examinations failed to elicit any evidence of disease in that region beyond occasional flatulence.

On the twenty-fourth day a hard, tender swelling, with redness, was found in the calf of the left leg, where there was much complaint of pain. There was also a small tender swelling in each axilla. About

this time an alteration in the patient's mental condition became noticeable. Sometimes she was much excited, at others she was depressed, frequently weeping and sobbing. On the twenty-seventh day she was quite "out of her head," and thenceforward she was completely delirious for the greater part of the time. On the twenty-eighth day (October 24th) it was found that an abscess had burst in the right axilla, and that another was forming in the left axilla, but no complaint had been made by the patient of either.

On the thirtieth day (October 26th) the patient passed into a state of complete dementia. She was unconscious, whining, crying out, sobbing, or chattering unintelligibly. The limbs and trunk were in constant slow, writhing movement, and she frequently tried to get out of bed. The discharges from the rectum and bladder were involuntary. She resisted the efforts of her attendants to administer nourishment, but with great difficulty they managed to get down about a quart of milk and half a bottle of champagne daily. Emaciation, which had progressed regularly from the beginning, was now very manifest.

About the thirty-sixth day (November 1st) the pulse and respiration became rapid, the former being at about 130, and the latter at 60 in the minute, and these rates increased gradually during the remainder of life. The general condition remained the same. Owing to the difficulty of feeding by the mouth the nourishment was given almost exclusively by the rectum. Abrasions were produced on the ankles, heels, etc., from the incessant motion of the limbs. On the forty-first day an abscess burst in the left axilla. On the sixty-fourth and seventieth days (November 29th and December 5th), respectively, she vomited all the contents of the stomach, being the only instances in which this symptom occurred. A few râles were noticed in the lower part of the back, but there was no dullness nor bronchial respiration. There was no cough. The calf of the left leg remained swollen, hard, and tender, but not red nor fluctuating. The right breast became hard and tender. Large dark-brownish spots of pigmentation were noticed on the abdomen, on the legs, about the knees, and on other parts of the body. There was desquamation of the skin of the feet and legs. She became moribund December 8th, and died December 9th (seventy-fifth day) at four o'clock and twenty minutes P. M.

There was no chill and no paralysis during any part of the disease.

The urine, examined by Professor Wood, October 14th, was of specific gravity 1012; acid; urea much diminished; uric acid increased; albumen a trace; all the phosphates diminished; indican diminished (the patient was a dark brunette); much free renal epithelium; a very few hyaline and finely granular casts. October 21st, an examination showed no material change. November 28th, the urine contained much pus, considerable albumen, and a few granular casts.

The record of the temperature is imperfect, as it was sometimes impossible to obtain a trustworthy observation for several days in succession, owing to the incessant movement of the patient. It was generally moderate, not rising above 102.5° F. until the thirtieth day, being the one following that on which the abscesses in the axillæ were discovered, when it was 103° F. in the morning, and 102.4° F. in the evening. After this date it remained below 102° F. until the sixty-fourth day, when it rose to 103° F., and fell again below

¹ Read before the Boston Society for Medical Improvement, November 14, 1881.

102° F. After the sixty-sixth day it rose daily, with evening increments, till the day before death, when it reached 106° F., falling the next morning to 105.2° F.

The pulse was high at the beginning (108 to 116 in the minute), and its rate began to increase on the twenty-ninth day, when it reached 120, corresponding with the rise of temperature. Between the sixty-first day and that of death it rose from 132 to 141.

The rate of respiration was not regularly noted, but it was always fast. Between the twenty-third and the forty-seventh day it varied from 41 to 62 in the minute. After the sixty-second day it gradually rose to 70, and occasionally to 86. On the morning of the last day it was at 70, at noon 30, shortly before death 15, in the minute.

Autopsy, by DR. E. G. CUTLER, twenty-three hours after death. The skull and integuments of the head were normal. The dura mater was also normal, and nothing pathological was found in the pia. Some of the convolutions of the vertex were atrophied, and the subarachnoid fluid was accordingly increased. The vessels of the base of the brain were normal. No change was found in the great centres of the brain. The heart was of natural size, and apart from a slight fatty condition of the muscular fibrils, as determined by the microscope, there was no change. The fatty degeneration was recent, and affected the papillary muscle most. There was a very small amount of fatty degeneration of the interior of the aorta, near the aortic valves. The left lung was oedematous in a limited area of the upper lobe; and near the lower portion of the upper lobe, anteriorly, there was a wedge-shaped, embolic infarction, with a softened centre; the pleura over it was thickened and covered by a thin false membrane. In small portions of the lower lobe, behind, there were several localized spots of lobular pneumonia of very recent date. A microscopic examination showed the cells filling the alveoli to be chiefly large epithelial cells, mixed with catarrhal cells. The bronchi contained a rather frothy secretion, not abundant nor sticky. The right lung also contained a number of the same localized pneumonic lobules, behind and below, and there had been one old adhesion at the apex. The bronchi also contained the same sort of secretion as the other lung. There were no embolic infarctions. The lung was quite oedematous. The spleen was very pulpy, the Malpighian bodies large, and in a condition of hyperplasia, as was also the pulp of the spleen. There were no embolic infarctions. The liver was engorged with blood, its acini fairly distinct in outline and rather large. Microscopic examination revealed a rather granular condition of the hepatic cells, and a slight icteric discoloration. The kidneys were the seat of old embolic infarction at the central portion, the spots being very minute and circumscribed. The tubules of the cortex were quite cloudy; casts were found in many of the tubules, and wandering cells outside the vessels in the region of the plugged vessels. The supra-renal bodies were healthy. The stomach contained some liquid food. Its mucous membrane was healthy, except in one portion, near the greater curvature, where there was punctiform ecchymosis, due to the presence of ingesta. The intestines and pelvic organs appeared to be healthy. In the left breast there was a small circumscribed abscess, and in the right one containing from two to four ounces of creamy pus.

Although I have entitled this paper a case of pye-

mia I am aware that it differs in some respects from typical examples of that disease, particularly in the absence of rigors and in the fact that no pus was found in the principal internal organs, as well as in the prolonged course of the case. But the progressive prostration of the patient and her nervous and mental condition, without adequate inflammatory symptoms or lesions, render it highly probable that she was suffering from some abnormal state of the blood, which the presence of pus beneath the integuments and in both mammary glands, and of wedge-shaped embolic infarctions in the lungs and kidneys would indicate to have been one of purulent infection.

The origin of the disease seems to be inexplicable. I saw the patient in good health, September 23d, the day she went to Newport. She returned home on the 25th in the same condition. There was nothing suspicious about the hygienic condition of the house in which she spent the summer, in that which she visited at Newport, or in her dwelling in town, and there has been no other sickness in either house. No local source of infection was revealed at the autopsy.

The treatment consisted in as much nourishment and stimulants as the patient could easily take, with quinine, bromide of potassium, and morphia, the latter chiefly by subcutaneous injection.

I omitted to mention that examination of the calf of the left leg, at the autopsy, showed nothing to account for the symptoms in that region during life.

SCHOOL HYGIENE: HEALTH OF GRADUATES OF THE CLEVELAND SCHOOLS.

THE tables which follow express in a concise form the results of the investigations into the health of young people at school, and recent graduates of schools of the city of Cleveland by a committee, on statistics of the Board of Education of that city.

In regard to the objects of the committee's investigation the words of the chairman may be quoted. He says:—

"As chairman of your committee on statistics—aided and assisted by the other members of this committee—I have, without expense to this Board, authorized a thorough and careful canvass, in statistical form, to be made of a large number of the pupils of our high schools, with a view of learning, first, why so many scholars who enter for this course drop out before it is finished, and, second, why so many, and especially the girls, have apparently suffered in health beyond the usual ills of life during their high school days. I am led to this course by a long period of observation of the pale cheeks, dull eyes, stoop-shouldered forms and worn and weary look of many of the pupils in the Central High, at an age when we expect to see bright faces, rosy cheeks, and erect forms, and the fact that not only here in Cleveland but elsewhere the high pressure principle of education seems to need an air-brake.

For the tabulation and diagrams of the main features of the report to the committee and the conclusions to be drawn therefrom we are indebted to its author, Dr. L. B. Tuckerman, of Cleveland. The report itself, not having been made to a medical body, is more general in its character than it otherwise would have been. These tables and diagrams will repay careful study, especially on the part of those interested in matters pertaining to

Whole number enrolled in Central High School during the year beginning September, 1880, and ending June, 1881: Boys, 316; girls, 410.

Withdrawn during the year: Boys, 56, 18%; girls, 108, 25% of the number enrolled.

The first perpendicular line in the diagram shows the time of entering; the second, that of leaving school. The upper figure shows the number of pupils in any given grade; the lower, the per cent. Width of lines corresponds to the latter.

I. HEALTH RECORD OF FORTY BOYS WHO LEFT THE HIGH SCHOOL, 1880-1881.

II. HEALTH RECORD OF EIGHTY-FIVE GIRLS WHO LEFT IN 1880-1881, AND ELEVEN WHO LEFT IN 1879-1880; NINETY-SIX IN ALL.

III. HEALTH RECORD OF FIFTY-EIGHT GIRLS WHO ARE NOW ATTENDING HIGH SCHOOL.

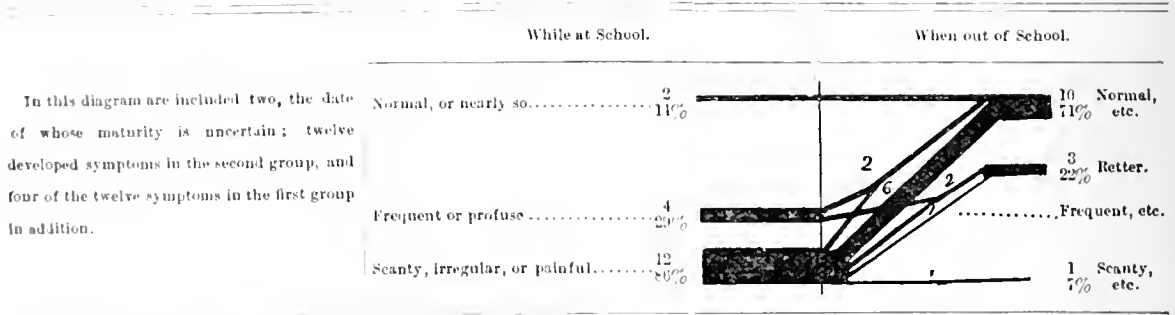

IV. HEALTH RECORD OF THIRTY-TWO LADIES, GRADUATES OF EITHER HIGH OR NORMAL SCHOOL.

V. MENSTRUAL RECORD OF SEVENTY-ONE WHO MATURED EITHER BEFORE OR SHORTLY AFTER ENTERING.

VI. MENSTRUAL RECORD OF FOURTEEN WHO MATURED DURING THEIR HIGH SCHOOL COURSE.

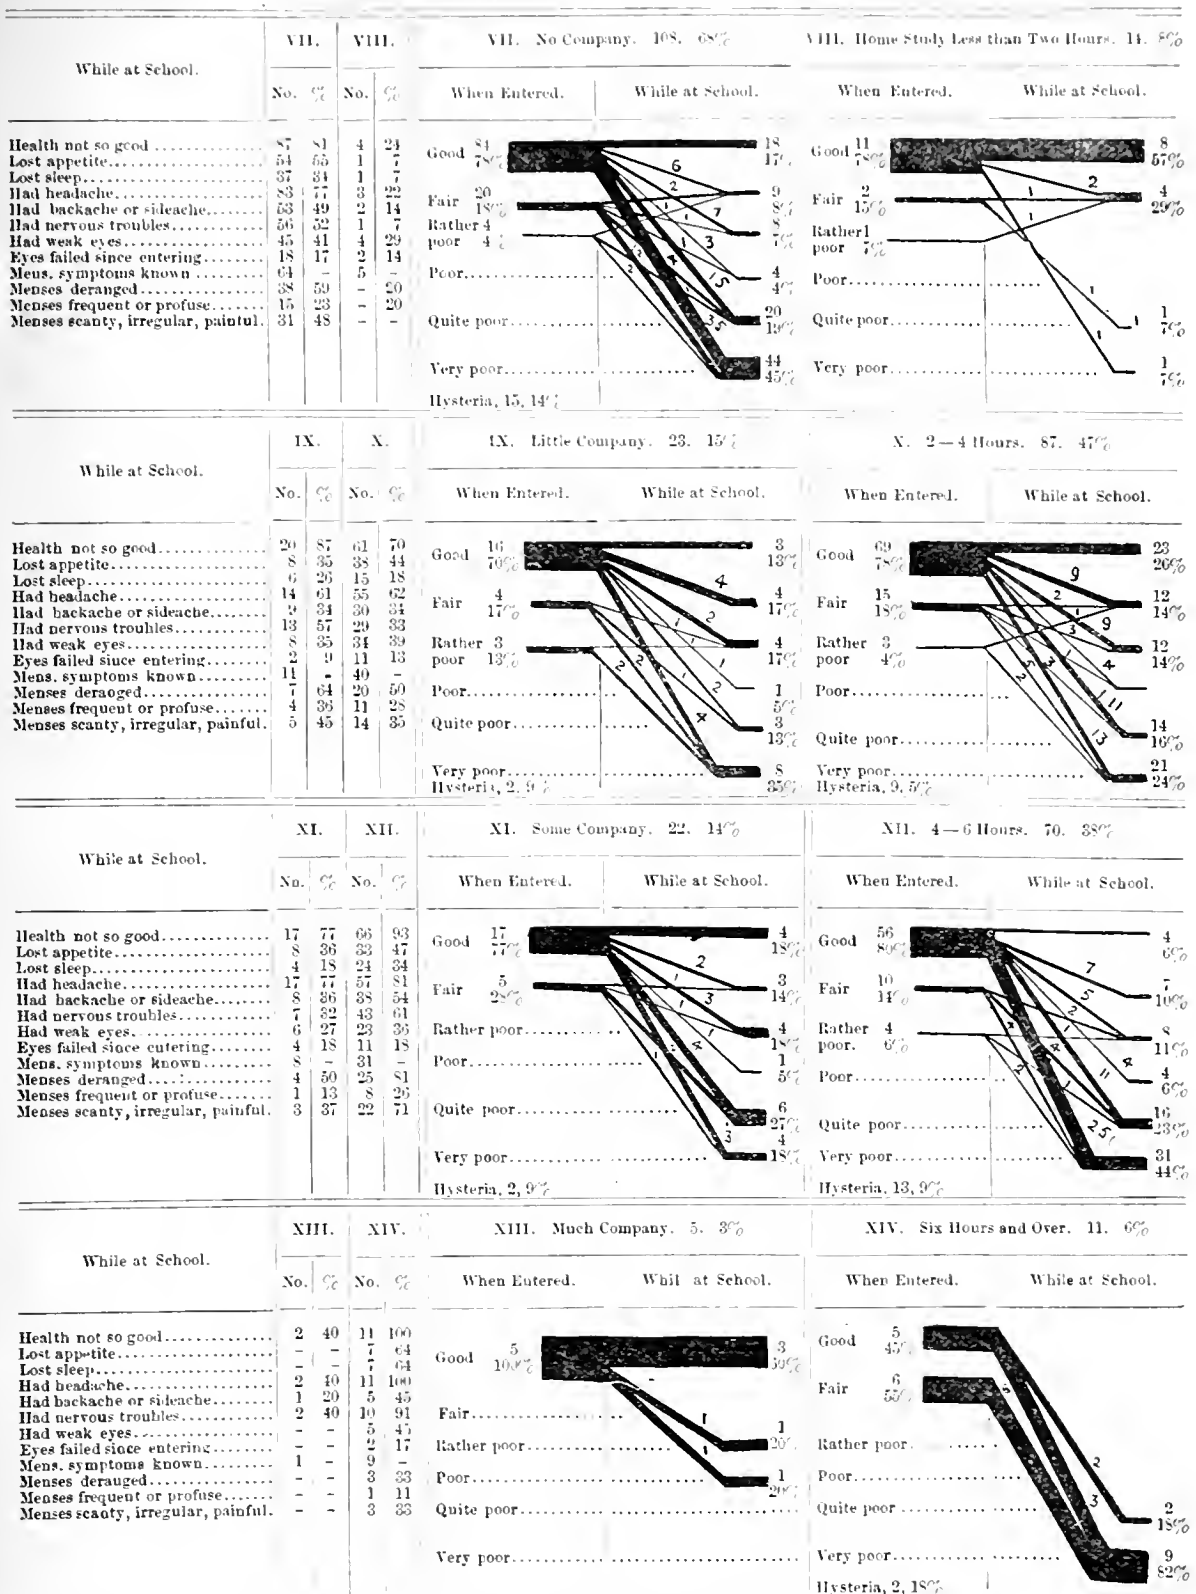

The grade of health in which each pupil was classed was determined partly by the number and partly by the severity of the abnormal symptoms developed during attendance at school. If a pupil developed a single symptom, for example, headache or loss of appetite, etc., he was classed as "Fair." Headache and loss of appetite and the like would class him as "Rather poor." Where all, or nearly all, the abnormal symptoms existed the case was classed as "Very poor."

The better average health of the boys will be at once noted, also the close correspondence between II and IV, owing to the marked failure

in health of fourteen in IV, during the last year of their course. The fact that the menstrual irregularities of the graduates are all of the second group is also worthy of note, as well as the enormous proportion of nervous troubles among them. In Diagram V, the five that descend from the level marked "Scanty, etc.," had their already existing irregularities aggravated during attendance at school. Many of these cases, of course, had not as yet become so severe as to come under professional care.

SOCIAL AMUSEMENT COMPARED WITH STUDY AS TO EFFECT ON HEALTH

Among the pupils included in diagram II., there were 11 cases of hysteria, 11% of the whole; in diagram III., 3 cases, 5%, and in IV., 5 cases, 10%. These last 5 cases all occurred among the 15 who were graduates of the Normal school.

The better average health among those pupils that take more social recre-

ation is very apparent. Also the rapid increase of abnormal symptoms with the increase of home study.

The increasing ratio of scanty, irregular, etc., menstruation, as home study increases, is also worthy of note.

school hygiene. Such study, Dr. Tuckerman points out, develops the fact that ill-health among the scholars increases directly as the amount of time spent in study beyond school hours, and inversely as the amount of recreation taken. He goes on to say:—

"Of course we do not seek to draw positive and sweeping conclusions from so few cases, but they show a certain drift, and they show also the necessity of further investigation,—and investigation not confined to one city only. We are working toward a definite end, not without opposition from some who think our present school system an almost sacred thing, and that end is the regulation of the sanitary affairs of our public schools by the Board of Health. We are trying, also, to bring about a systematic registration of the pupils in our public schools as to their physical condition from time to time.

"Such a registration would go far in a year or two to settle many questions now *sub judice*. The Health Boards of Baltimore, Milwaukee, Minneapolis, and Chicago are interesting themselves in this matter, and I hope that a wide interest may be aroused in the work of *gathering facts* as a basis for the solution of this greatest of our sanitary problems."

PROGRESS IN PHYSIOLOGY.

BY GEORGE M. GARLAND, M. D.

MUSCULAR TONICITY.

THE phenomena embraced under the head of muscular tonicity have been almost universally referred to the influence of nerve centres, either central or peripheral, and the muscles themselves have been credited with the subordinate rôle of responding to the impulses generated in such centres. Small arteries separated from the central nervous system will in a short time recover from their paralysis, and therefore their tonicity was supposed to be due to peripheral ganglia, while muscular dilatation was thought to be produced by the action of certain central nerves which neutralize the stimulating influence of the peripheral cells.

When strong pressure is made across the middle of the ventricle of a frog's heart, the apex ceases to beat; it becomes paralyzed. This was explained on the assumption that the apex contains no nerve ganglia, and hence the paralysis. Merunowicz,¹ however, discovered that an apex thus paralyzed will resume beating if stimulated by the constant current or by an artificial blood supply. This immediately necessitated the hypothesis that the apex does contain its own nerve centres, although no nerve cells can be detected microscopically.

Gaskell² reviews this entire subject in an interesting article, in which he is disposed to recognize the muscles as responsible to a certain extent for their own action. He fed a frog's heart with different kinds of artificial food, and observed that an alkaline fluid favored the contraction of the muscle, while an acid fluid produced an atonic condition of the same. Seizing upon this important fact as a hint, he argues that it is worth while to consider first the possible influence upon the muscles of the chemical changes which are constantly going on within themselves and within the

blood-vessels, before resorting to purely hypothetical and invisible nerve centres.

Interchange between blood and tissue cells is constant, both in activity and in rest. During activity the waste products are more numerous. They pass directly into the lymph spaces, where they bathe the small vessels, and he thinks that the degree of alkalinity or acidity of this bath must have a direct effect upon the tonicity of those vessels. Severini³ says that CO_2 formed by the activity of muscular tissue brings about such an alteration of shape in the nuclei of Golubew as to cause an enlargement of the calibre of the capillaries. The effect of oxygen is just the reverse. The nuclei become more spherical, project into the lumen of the capillary, and thus diminish the calibre of the same. We know that the activity of all muscles produces an acid, and the experiments of Heidenhain upon the pancreas render it probable that acid is also formed by glandular activity.

Although Gaskell proves nothing in his article, he opens up an extremely interesting and suggestive field of inquiry.

CORONARY ARTERIES.

The theory of Thebesius and Bruecke, that the coronary arteries of the heart are filled during the cardiac diastole by the aortic rebound, and that their orifices are closed during the cardiac systole by the aortic valves, has been hotly contested by numerous observers. Drs. Martin and Sedgwick⁴ have recently investigated this point by attacking the arteries *in situ*. After numerous failures they finally succeeded in introducing a canula into the coronary artery of a narcotized dog. Then placing a canula in the carotid artery, they were able to obtain simultaneous tracings from the two.

They found the blood pressure of the coronary arteries to be very high, nearly if not quite equal to that in the carotids. They also proved that the coronary and carotid pulses are practically *synchronous* in time, and that every feature of the carotid tracing was simultaneously and perfectly repeated in the record of the coronary artery.

This seems to prove conclusively that the aortic valves do not cover the mouths of the coronary arteries, and that those arteries are filled during systole.

STUDY OF FROGS' BLOOD.

A number of observers have noticed that frogs' blood, during the spring months, contains numerous formations which possess independent living motion, and are distinct in shape from all other ordinary constituents of the blood. These intruders are about the size of the red corpuscles, and resemble well known infusoria, so that they have been actually classified as parasitic infusoria. Gruby gave them the name *trypanosoma sanguinis*, and Mayer described two species of the same as *paramoecium boricatum* and *amaba rotatoria*. Gaule⁵ has made a prolonged study of these creatures, and decides that they are not independent animalcules, but are simply metamorphosed white blood cells. In studying the conditions of their appearance and preservation he found that they are much more abundant in the spring, and that they can exist only in blood or in a one fourth or one half per cent. solution of salt.

⁵ Beobachtungen der farblosen Elemente des Froeschblutes. Aus der Physiol. Anstalt zu Leipzig.

¹ Lelwig's Arbeiten, 1875, p. 132.

² The Journal of Physiology, vol. iii, No. 1, p. 48.

In an alkaline solution they dissolve immediately, and in acetic or hydrochloric acid they shrink into round, coarsely granulated, colorless cells.

They are most abundant in the blood of a frog which has been previously thoroughly bled. He says that one should pith a frog, bleed him from the abdominal vein, and keep him in a moist dish for two or three days. If he be then killed one will find a very thin blood in his heart, which not only contains a number of trypanosoma, but also a number of elements from which trypanosoma will develop on the object-glass. If the preparation be surrounded by paraffine and kept at a temperature of 32° C. the development and movements of these curious cells can be watched at leisure. At first the white blood cells send out a slender projection like a whip-lash, which vibrates actively and stirs the water around the cell. This lash is so slender that it can be seen only with a high power (immersion 11 of Hartnack). Then the granular protoplasmic contents of the cell are seen to be in commotion, and several (three to seven) fine projections appear on the side opposite the whip-lash. These projections vibrate actively, and may again be withdrawn, or they may become so vigorous as to move the entire cell. The cell continues to change its form. Its border projects here and there, and it may assume very grotesque shapes. He concludes, therefore, that the trypanosoma are merely leucocytes.

In questioning regarding the purpose and aim of such eccentric cell activity, Gaule remarks that these cells, with their whip-lash appendix, bear a strong resemblance to spermatozoa. Inasmuch as they are most common in the spring of the year, that is, during the breeding season, he remarks that those conditions which affect the sexual products and cause the development of peculiarly-endowed cells in the sexual organs also seem to exert a powerful influence upon the protoplasm of other cells.

NORMAL TEMPERATURE OF THE BODY.

Dr. Jaeger¹ reports a series of observations upon the normal temperature of a number of soldiers in Tübingen. Eleven men were chosen. They were fed on ordinary diet, but were confined to their beds, and the temperature was taken in the rectum every hour for two days. The appended extract, giving the tabular results for three of the men, will serve as examples of them all.

The highest average which he obtained from any man was 37.35°, and the lowest average was 36.95°, giving a difference 0.4° between the two. Reckoning up all of his observations he found that the average normal temperature for the twenty-four hours is 37.13°. This is in accord with the results of Jürgensen, who says that the average temperature of adult men for each day is a typical constant. Whatever influence may temporarily raise the temperature, a reaction will take place which will restore the sum total to the typical average.

With regard to the hours of absolute maximum and absolute minimum temperature, Jaeger noticed that the minimum occurred, sixteen times out of twenty-two, at two o'clock in the morning, and once it came as early as eleven o'clock. The maximum temperature appeared four times before noon, six times between twelve and one o'clock, and ten times after four o'clock.

¹ Ueber die Körperwärme der gerunden Menschen. D. Arch. f. k. Med. 29 Bd. 5 an 6 Heft 3, 516.

Jaeger next examined a series of men who were employed at hard work in a warm but well-ventilated room. He found that the temperature is elevated by such work. But the law of compensation still holds, and the reaction of the temperature during repose is sufficient to keep the average constant. The maximum temperature of one man reached 38.1° at four P. M., while his minimum temperature was 35.6° at midnight. His average temperature for two days 37.18°, that is, only .05° more than that of the men who lay in bed.

Reports of Societies.

THE NEW YORK NEUROLOGICAL SOCIETY.

THE QUESTION OF REFLEX PARALYSIS FROM GENITAL IRRITATION.

STATED meeting, November 1, 1881. Dr. Langdon C. Gray, of Brooklyn, who had been announced to read a paper on the above topic, stated, before commencing the reading of it, that the title was properly the following: "The effect of genital irritation in the production of nervous disorders." In giving a *resumé* of the history of the subject, he mentioned that the first paper in regard to it which attracted the general attention of the profession was that of Mr. Stanley, which appeared in 1833. He had found that in certain cases of nervous disorder there were marked lesions in the genito-urinary apparatus, while none could be discovered in the spinal cord, and therefore concluded that the trouble was reflex. The position thus taken received the support of a number of distinguished writers, and was for a long time accepted by the mass of the profession. It was not till 1856 that the first critic of these views appeared in the person of Mr. Gull, now Sir William Gull, who maintained that the facts reported in Stanley's cases were utterly worthless as proofs. In 1861 he still more forcibly set forth his opinions in a paper which Weir Mitchell had charac-

terized as nothing less than brilliant, contending that, although there may have been no gross lesions of the spinal cord in Stanley's cases, it was altogether probable that there had been microscopic lesions. Primarily influenced by Gull's able papers, the tide of professional opinion now ran in the opposite direction, and Dr. Weir Mitchell had even suggested that the trouble about the genito-urinary apparatus might perhaps be the result of lesions in the nervous system. In 1873 Brown-Séquard had appeared as the champion of the old doctrine; but this had been a mere episode in the history of the subject. At the present day all the leading authorities had discarded Stanley's opinions.

In this country, Dr. Gray continued, the question had assumed a somewhat different phase, on account of the attention that had been attracted by Dr. Sayre's two papers on want of coördination and partial paralysis due to genital irritation. Brown, Bryant, and Barwell had also reported cases in England, and Dr. Otis, of New York, had supplemented Dr. Sayre's cases with a number of analogous ones of his own. The matter had excited great interest in the minds of the profession, and one gentleman had gone so far as to claim that he had cured cases of cerebral softening and of general paralysis of the insane by means of circumcision. The writer remarked that the histories of Sayre's cases were, as a rule, so incomplete that it was difficult to form a definite opinion in regard to them, and then criticised a number of them singly. Thus, in the first case reported, it was mentioned that the penis was inflamed, and he claimed that the patient instinctively flexed his legs in order to relieve the pain that he suffered, and that he refused to walk on account of the aggravation of the pain thus caused. After referring briefly to the other cases of the series, Dr. Gray went on to say that the first case reported in the second series published by Dr. Sayre was evidently one of well marked spastic disease, while the second was probably a case of myelitis affecting the anterior horns of the cord. He remarked incidentally in this connection that circumcision was sometimes of great service in myelitis, and referred to a patient of his own in which this was the case. The case was given more in detail later on in the paper. Dr. Sayre's third case (in the second series) he believed was probably one of meningeal hemorrhage, with secondary degeneration of the lateral columns of the cord. The two cases reported by Mr. Barwell were also unsatisfactory, and in not one of the eighteen cases of reflex paralysis supposed to be dependent upon genital irritation, which had thus far been published, was there conclusive proof of this relation of cause and effect. While preparing this paper, Dr. Gray had taken the trouble to write to Drs. Weir Mitchell, Jewell, Edes, Hammond, Seguin, and a considerable number of other well-known neurologists, to inquire if they had ever met with a single case of paralysis arising from this cause, and they had all replied in the negative.

Still, notwithstanding the fact thus substantially demonstrated, there was just reason to believe that operative procedures not infrequently afforded relief in the course of nervous disease. Thus, in a case of post-pleuritic paralysis, in the hands of Dr. C. Fayette Taylor, the operation of circumcision had been followed by the greatest possible benefit. Dr. Gray then gave a detailed account of three very interesting cases in his own practice. The first was one of tubercular meningitis, in which circumcision had the effect of

causing the child to sleep much better, increasing its appetite, and rendering its temper less irritable. After a time, however, the unfavorable symptoms returned and seven months after the operation the patient died, when an autopsy proved the correctness of the diagnosis that had been made. The second was one of myelitis involving the anterior cornua, which showed very marked improvement after circumcision. Yet for four months previous to the operation the patient had been under treatment without any improvement whatever. In the third case the patient was a male twenty-three years of age, who had a fine rhythmic tremor of the upper and lower extremities from the effects of brass-poisoning. For seven years he had been employed in some brass works, and had been obliged to breathe a fine copper dust. In this case a complete cure was effected by circumcision, and by the wearing of a respirator.

Dr. Gray believed that the improvement that was seen in such cases after circumcision was largely due to the rest that was afforded the patient by removing a source of irritation from an exquisitely sensitive organ. The cutting or tearing resorted to in the operation made a decided impression upon the nervous centres, and acted in the same way in which a fit of alcoholic intoxication sometimes broke up an attack of *tic dolo-reux*. In one case of epilepsy and kleptomania he had known the greatest possible relief to follow an operation for the removal of some old cicatricial tissue from the scalp. The fact that operation afforded relief in such cases, however, should not render one the less cautious in accepting the statement that reflex paralysis depends upon genital irritation. The cases of Otis and Bryant, it was true, did serve to afford some ground for such an opinion; but if they were carefully examined, it was seen that there was no real ground for it.

Dr. Gray next mentioned some experiments upon animals which had resulted in causing reflex paralysis by means of temporary pressure upon nerves, and then stated his firm conviction that at present it could not be accepted that paralysis ever depends on coexistent genital irritation. At the same time, it was perfectly right and proper to remove this coexistent source of irritation, and it was plainly the duty of the medical attendant to do this. But while paralysis was not caused by genital irritation, it was altogether probable that other and slighter nervous troubles might depend upon it.

At the conclusion of the paper Dr. Sayre, being called upon by the chair, remarked that he had learned many things from Dr. Gray's essay, and especially in regard to the history of the subject under discussion. When he published his first cases, in 1870, he thought he was the first in the profession to call attention to the matter, and in this he had been confirmed by the vast number of letters attesting the apparent truth of his statements, that he had received from all parts of the world. One surgeon in Edinburgh, Mr. Black, had embodied nearly the whole of his paper in his systematic work on Genito-Urinary Diseases. He did not like to gainsay the assertions of the writer of the paper, and yet he could not see how organic disease of the cord (whether this consisted in hardening or softening of its tissues) could be cured in the short time in which some of the cases under his charge had gotten well. He was perfectly willing to acknowledge that he had probably not been so minute in the description of his cases as the importance of the subject demanded;

but he certainly could not doubt that relief of the paralysis and restoration of power to the muscles had followed the measures which he had adopted in his treatment. The cases now amounted to nearly one hundred in all, and as soon as he was able to get the time to do so he hoped to lay them before the profession. Instead of mentioning his own cases on this occasion Dr. Sayre read a number of extracts from letters which he had received from a number of well-known physicians and surgeons in different parts of the country, in which some very successful cases were reported. He spoke of one striking case of his own, however, in which paralysis seemed to be induced by tightly constricting the penis with a string, and which entirely disappeared after the removal of the cord. The necessity of operating when there was an adherent prepuce was now generally admitted, and his success in removing paralysis by this means had now been so great in such a number of cases that he could hardly believe that organic trouble was present in the greater number of them. While, however, Dr. Gray was of the opinion that the genital irritation was only a coincidence, he was very glad to find that he was nevertheless an advocate of operative procedure for its removal. In conclusion, Dr. Sayre related a case which had been sent him by Dr. Kuapp, the distinguished ophthalmologist. The patient was a man of thirty-five, who was excessively nervous, and was apparently suffering from atrophy of the optic nerve. It was found that he had marked phimosis, and, strange to say, after circumcision his vision became perfectly restored, while all the nervous symptoms disappeared.

Dr. F. N. Otis said that he had hoped to find something new in Dr. Gray's paper; but in this he had been disappointed. From the special character of his practice he had not had the opportunity of seeing cases of paralysis like Dr. Sayre; but from his own experience in regard to the effect of irritations about the genito-urinary tract he was perfectly prepared to accept the truth of all the latter's statements on the subject. He had certainly seen a very large number of cases of nervous troubles of other forms arising from this cause, and the records which were now in his possession, he was convinced, would prove beyond a doubt that there was something more than a coincidence in the relief of such troubles by operations upon the genito-urinary apparatus. Thus, in the case of a gentleman who had consulted him on account of profound melancholia he had found a contracted meatus, and though he merely distended the orifice to some extent, this simple procedure had the happiest possible effect in relieving the mental depression of the patient. In a few weeks, however, the trouble returned; but the melancholy was again dissipated in the same way. For three or four years the dilatation was repeated from time to time (always with the effect of temporary benefit), and finally the gentleman consented to have the meatus permanently enlarged by a cutting operation; since which time there had been no return of the trouble whatever. In this and similar cases, Dr. Otis remarked that he recognized a reflex irritation upon the brain. The next case he mentioned was that of a medical student who had epilepsy (suffering from five or six attacks of *petit mal* a day) which seemed to be dependent on a contracted meatus. He had performed three operations upon him altogether; the first two being followed by marked relief, and the third by an entire cure, as there had been no return of the epilepsy

since, and the patient was now an interne in one of the New York hospitals. In another case of the same trouble the patient had phimosis, and complete relief from the epileptic attacks was secured by the operation of circumcision. A third case was also entirely cured by the removal of an elongated prepuce, without other treatment. This was one of weakness in the genital apparatus in which there were seminal emissions and premature ejaculations, and the patient had previously been under treatment for a long time without avail. He could not believe that such cases were mere coincidences; but, on the contrary, felt convinced that these genital irritations did cause reflex troubles in the brain and spinal cord. In concluding, Dr. Otis mentioned a case which was sent to Dr. Taylor as one of hip-joint disease. It was true there was a halting gait; but this was the only evidence of the affection, and as the boy had an adherent prepuce, this was removed; after which considerable relief followed. As there was still some lameness remaining, however, Dr. Taylor brought the case to him, when he found that the patient had a contracted meatus. As it was thought worth while to make the trial, the meatus was extended, and by the very next day all the lameness had disappeared. This case showed that it was important in such patients to examine not only the prepuce, but the meatus urinaris. It was only fair to state, that in the above patient the lame leg was slightly smaller in its measurements than the other limb.

Dr. Frederick Sturgis thought that one distinction had been lost sight of in the discussion, namely, that between reflex paralysis and reflex irritation. The point that the writer of the paper had made was, that in time the paralysis would return in cases such as Dr. Sayre had reported. With regard to the fact that genital irritation gave rise to nervous symptoms of various kinds, he thought that no one who had had any experience in genito-urinary affections, could doubt it. But as to the question of paralysis he would suggest that the verdict of—not proven, would apply to Dr. Gray's cases equally as well as to Dr. Sayre's. He saw no reason, he continued, why men should not be hysterically paralyzed as well as women. Dr. Sturgis then related an interesting case of a female patient under his care at Charity Hospital, on Blackwell's Island, and concluded by thanking Dr. Gray for the statement that he had made in one part of his paper, that an elongated prepuce was always a cause of disease.

Dr. Seguin agreed with Dr. Otis in the opinion that a vast number of nervous symptoms had their origin in genital irritation; yet, in all his experience, he had not once seen a case of paralysis which he could attribute to that cause. At the same time, however, he was very far from denying that paralysis never did arise from preputial irritation. He had hoped that Dr. Jacobi would be present this evening, but as he was not, he would mention that in a recent conversation the latter had stated that he also had never met with such a case; and it was probable that Dr. Jacobi had seen more of children's diseases than any other medical man now in the city. In the course of the paper the writer had stated that Dr. Martin had called attention to the fact that the operation of circumcision seemed to have the effect of narrowing the meatus urinaris, and that this result was frequently noticed in the case of Jews. Dr. Otis, on the other hand, had distinctly denied that this was really the fact; but he himself had noticed this tendency in a considerable number of in-

stances, and he had had quite a large experience with Jewish patients.

Dr. George M. Beard mentioned two conclusions that he had arrived at. The first was that the presence of contracted meatus or redundant foreskin in the vast majority of instances bore no relation whatever to the condition of the nervous system and the general health, and the second, that there never was any immediate result from operation, as far as he was able to judge. Only in a comparatively few cases could the brilliant results achieved by Sayre and Otis be obtained; and on the contrary, he believed that these operative procedures sometimes did harm, instead of benefiting the patient. In one case that he recalled the man had become impotent after an operation for stricture, and no course of treatment that he could devise had been able to restore him. In regard to the Jews he had found them as a class exceedingly liable to nervous disorders; and he concluded, therefore, that circumcision was not much of a protection against such afflictions.

After remarks by Dr. Spitzka and others, the discussion was brought to a close by the reader of the paper.

BIOGRAPHICAL SKETCHES OF DECEASED MEMBERS OF THE OBSTETRICAL SOCIETY OF BOSTON, WITH AN OUTLINE OF THE EARLIER OBSTETRICAL HISTORY OF BOSTON AND VICINITY.¹

BY WILLIAM W. WELLINGTON, A. M., M. D. (HARV.),

Member of the Society, etc., etc.

"Foot-prints on the sands of time."

AMONG the passengers of the Mayflower, who landed at Plymouth in December, 1620, was Dr. Samuel Fuller. He was the first regularly educated physician in New England. He was also a deacon of the church, and his services were in demand both for the souls and the bodies of the Pilgrims.

He must have had a sad time during his first winter in Plymouth. Nearly half of those who landed in December died before spring. We know little of what they suffered, or of what was done for their relief. But the mortality was enough to paralyze the energies of any physician.

Dr. Fuller's practice seems to have been heroic. In a letter to Governor Bradford, dated June, 1630, he writes: "I have been to Matapan, and let some twenty of those people bleed." Good Dr. Thacher is at a loss to determine what disease prevailed among "those people" that required such a loss of blood "in the warm season of June." If the Old Colony pilgrims were subjected to the same treatment as were the unfortunate Matapanese we may perhaps account in part for the remarkable mortality of that first winter in Plymouth.

Dr. Fuller died in the summer of 1633. His wife at a later period became a midwife. We know but little of her except "that she was held in esteem." She probably did most of the obstetrical work in the colony, and as her husband was the first physician so she was the first midwife in Massachusetts.

It is obvious that the obstetrical art must have been almost coeval with mankind. Until recently, among

all nations, and in all times, this art has been practiced by women. From the passages of Scripture where midwives are mentioned it is plain that women were the only practitioners of obstetrics among the Hebrews and Egyptians. The first recorded case of labor was under the care of a midwife, and was a fatal one.² According to the account in the Book of Genesis, "the soul of Rachel departed from her in giving birth to her son Benjamin."

It should be stated to the credit of the Hebrew midwives that, when commanded by the King of Egypt to kill all the male children who should be born under their care, they feared God and refused to obey, and thus "saved the men-children alive." These midwives not only "feared God," but they were bright women. When the king called for them, and asked them why they had not obeyed his command, they promptly replied: "Because the Hebrew women are lively, and are delivered ere the midwives come in unto them."

The Greeks and Romans also confided this important branch to the female sex, a surgeon being occasionally called in desperate cases. But the dangers of child-birth could not have been greatly diminished by the exercise of the best skill which medical men then possessed in this department.

Ancient medical writers lay down sundry rules for guidance in difficult cases of labor; but generally these rules are not of great practical value. Frequent mention is made of midwives. Phanarete, the mother of Socrates, and Aspasia, the friend and companion of Pericles, belonged to this class.

The first obstetrical treatise of which we have any knowledge was written in 1513 by Eucharius Rhodion, a German, and was translated into English, in 1540, by Richard Jonas. It is evident from this book that at the beginning of the sixteenth century midwifery was a sorry art, and that the lot of parturient women in those days must have been deplorable.

The employment of men in the practice of midwifery goes no farther back than the middle of the seventeenth century. In 1663, Madame de la Vallière, the mistress of King Louis XIV., saw fit to place herself in her first confinement under the care of Clement, a surgeon of high reputation. When labor came on he was conducted with great secrecy to the house where the lady resided. Her face was covered with a hood, and the king is said to have hidden himself behind the curtains in order to be sure that everything was right. The same surgeon was employed in the subsequent labors of this lady; his practice being successful other ladies of note were led to employ surgeons on similar occasions, and accoucheurs, as they began to be called, came into repute.

It is a singular fact that while, until the middle of the seventeenth century, midwifery in Europe received from medical men but little attention in comparison with physic and surgery, the reverse was the case in China. There, both physic and surgery are in a low condition; but, for hundreds of years, midwifery has been practiced by a set of men destined, and we may infer educated, for the work by the government. These men are called whenever a woman has been in labor more than a specified number of hours. A proportionate number of such persons is allotted to each district containing a certain population. This course was originally adopted "because annually many women

¹ Read June 11, 1881. Prepared at the request of the President, and printed for distribution among members of the Society only.

² Genesis xxiv. 24-26 may perhaps be considered as recording a still earlier case — of twins.

died undelivered, whose lives, it was thought, might have been saved."

Tracing down the obstetrical history of Massachusetts for a century and a half, from the days of Mrs. Samuel Fuller, of Plymouth, midwife (1633 *et seq.*), we find midwifery, as in European countries, largely in the hands of women. A few of them may be named:

Mrs. Ann Hutchinson, who resided in Boston about the year 1637, had the reputation of being a very skillful midwife. She was banished, however, from the colony for agitating measures against the state.

In the town records of Rehoboth it is recorded that, on the third day of July, 1663, it was voted "that Mrs. Fuller, of Plymouth, be invited to come and dwell among us, to attend on the office of midwife, to answer the town's necessity, which at present is great."

In Blake's Annals of Dorchester is this record: "1705. This year died old Mrs. Wiat, widow, being ninety-four years of age, having as a midwife assisted y^e birth of one thousand one hundred and odd children."

Mrs. Elizabeth Phillips, wife of John Phillips, was born in Westminster, England, and was commissioned by John, Lord Bishop of London, in the year 1718, to the office of a midwife. She came to Boston in 1719, and, according to an inscription on her gravestone, "by the blessing of God brought into this world above three thousand (3000) children." She died May 6, 1761, aged seventy-six years.

A noted midwife of Boston was Ruth Barnaby, who practiced her calling for more than forty years, and died in 1765 at the mature age of one hundred and one years.

Mrs. Ruth Stebbins, born in 1769, is spoken of as an excellent and successful nurse, who labored untiringly to benefit her sex.

It would be interesting to know what success attended the practice of midwifery during this century and a half. The midwives could not have received a medical education worth the name. What little they knew was derived from their own imperfect observation or from the experience of others as ignorant as themselves. They must have been ill-equipped for their work, and probably the work was not well performed.

At any rate, in the latter half of the eighteenth century, the condition of obstetrical practice was such that the medical profession began to think that a change was necessary. Midwifery in Massachusetts was behind the times. In France, since 1663, when Madame de la Valliere had the good sense to employ Julian Clement, this branch had been advancing. An obstetrical department had been established at the *Hôtel Dieu*, in Paris, with public instruction and lectures. In England, Dr. William Harvey, after giving publicity to his discovery of the circulation of the blood in 1628, either from inclination or necessity, engaged in the practice of midwifery. In this way he acquired a practical knowledge of obstetric work, which enabled him to write, and about the year 1653 to publish, his *Exercitatio de Partu*.

Dr. John Nowbray, in 1724, gave public courses of lectures on obstetrics at his house in London. A syllabus of these lectures (twenty in number) was published under the title *Midwifery brought to Perfection*.

Edmund Chapman was the second public teacher of midwifery in London, and is said to have been the

first to describe the forceps, originally invented by Peter Chamberlen in 1610, and kept secret by him.¹

Sir Richard Manningham, in 1739, established a small hospital in Westminster for the reception of parturient women, which was the first institution of the kind in Great Britain. Here he gave lectures and clinical instruction. He was a man of much learning, and published several essays relating to the practice of midwifery.

In 1740 William Smellie came to London from a small country town in Scotland, and for twenty years taught and practiced in that city. He became a celebrated obstetrician, and his name is respected wherever the obstetrical art is cultivated. He was an eminent lecturer, and among his pupils were many who afterwards became distinguished men. He published a treatise on midwifery, and also a volume of fine anatomical plates.

Contemporary with Smellie was William Hunter. Born in Scotland, a pupil of William Cullen, and his partner afterwards, he went to London in 1741. The most elaborate and brilliant of his publications, the *Anatomy of the Human Gravid Uterus*, appeared in 1775, and gained for him a foremost rank among obstetrical writers. In 1778 he published *Reflections on the Section of the Symphysis Pubis*, designed to show the impropriety and inutility of that surgical operation. He gave special courses of lectures on midwifery, and became accoucheur to the Middlesex, and afterwards to the British Lying-In Hospital. He was a man of polished manners and cultivated mind, and was a successful competitor of Smellie in practice. He died in March, 1783.

Dr. Thomas Denman, a pupil of Smellie, and himself an able teacher and writer, says in relation to this period: "The English may be said at this time to have been in full possession of the obstetrical art; books written in the neighboring countries had been translated, public lectures given, and a hospital established, for its improvement, and men of ability and eminence were engaged in its practice."

But in Massachusetts no such progress had been made. Obstetrical work was still largely in the hands of uneducated and unqualified persons, mostly women. When Dr. Holyoke settled in Salem, in 1749, as we learn from his biography, this department of the healing art was entirely in the hands of ignorant midwives, and the physician was only called in extraordinary cases, or to rectify the blunders of these practitioners. The first case in which he was "persuaded to engage" occurred in 1755, after he had been in practice six years, and it was not till four years afterwards that he makes record of a case "which was the first common easy birth that ever came under his management." The necessity of elevating this important branch was immediate and imperative. The time had come for a new departure, and the man came with it. His name was James Lloyd.

Dr. James Lloyd was born at Long Island, in March, 1728. His family was ancient and reputable. One of his ancestors was "Doctor in Physic" to Queen Elizabeth. At an early age he was sent to Stratford, in Connecticut, to get his education; where, and at New

¹ The forceps, or something similar to it, was probably used at an earlier date. An instrument resembling a modern obstetrical forceps was exhumed from the ruins of Pompeii. Avicenna, an Arabian physician (born A. D. 980), after advising a fillet around the child's head to aid in its extraction, says, "when this fails apply forceps."

Haven, he remained several years. At the age of seventeen, he left Connecticut for Boston, and entered upon the study of medicine with Dr. William Clark, one of the noted physicians of his time, under whose instruction he continued for five years. In 1750, at the age of twenty-two years, at the suggestion of the physicians of Boston, and chiefly for the purpose of thoroughly qualifying himself for the practice of obstetrics, he embarked for England, and devoted two years to an attendance on the London Hospitals. Here he had the opportunity to witness the practice of Cheselden and Sharpe, to attend the lectures and private instructions of William Hunter, of William Smellie, and of Joseph Warner, the principal surgeon of Guy's Hospital. He also made the acquaintance of John Hunter, and of other prominent medical men in London. On leaving England he received an autograph certificate from Mr. Warner, closing thus: "As I know him to be perfectly well qualified in his profession, I think it incumbent on me to recommend him in the strongest manner I am capable of."

In 1752 Dr. Lloyd returned to America, and, at the age of twenty-four years, began practice in Boston. Occupying a good social position, fully equipped for his work as physician, surgeon, or obstetrician, he soon gained a high professional reputation, and a large and lucrative business. He is said to have included in the list of his patients every member of the clerical profession in Boston. "He scarcely," says Dr. Thacher, "enjoyed an undisturbed night's rest, and the residents of the street in which he resided as regularly expected to hear, during the stillness of the night, the well-known clatter of his horse's feet as the cry of the watchman."

Dr. Lloyd was the first regularly educated physician in Boston who paid special attention to midwifery. In this branch he manifested cleverness and skill. With signal ability and devotion he led the way in raising it from the low condition into which it had fallen, and placing it where it rightfully belongs, and where we hope it will long remain, in the hands of well-educated physicians. His professional books were not preserved, and no record remains of the amount of his obstetrical practice. It was undoubtedly very large.

He was a lover of horticulture. His estate on Pemberton Hill, previously a gravel-bank, was transformed into a beautiful garden, stocked with choice fruit trees and vines, and adorned with lawns and terraces. It was his habit to carry fruit from this garden to sick children under his care, calling it "God's medicine."

He was a social man, and entertained his friends with a generous hospitality. He kept open house, especially welcoming the visits of merchant captains, who came hither from China, the East Indies, and other distant places. He was the constant recipient of rare and beautiful presents from his foreign guests, and his house was full of such treasures.

He was a man of elegant appearance and manners. He kept fine horses. One in particular, coal-black, of great speed, which he often rode, went by the name of "Steel-Trap." He owned on Long Island a great deal of land, then wooded, which he frequently visited for recreation.

He received, in 1790, from Harvard University, one of its first honorary medical degrees.

He was a conservative in politics, and did not sympathize with the patriots in the early stages of the war of the Revolution. But he was a wise man and kept his own counsel, and so weathered the storm.

He lived to the age of eighty-two years, and died in March, 1810. He was greatly honored, and beloved by the whole community, and his death made a deep public impression. His funeral, with its stately ceremonial, is remembered by some of our elder citizens.¹

The following passage is the close of the funeral sermon delivered on the occasion of his death by Rev. Dr. Gardner, Rector of Trinity Church: "If the value of a citizen is to be estimated by his public and private utility, this town has never, perhaps, sustained a greater loss. For nearly fifty-eight years he was in extensive practice, and there is, perhaps, no physician now living to whom so many individuals have been under professional obligations. The public have lost in him a practitioner of first-rate skill and ability: polished society, a gentleman of consummate good breeding; his country, a firm friend; the poor, a most benevolent benefactor. He has descended to the grave full of years and honor, an ornament to his profession, and an example to his survivors."

Dr. Isaac Rand was a pupil of Dr. Lloyd. He settled as a physician in Boston in 1764, and soon gained distinction. He fully sympathized with Dr. Lloyd in his obstetrical work, and cooperated with him in his attempt to improve the practice of midwifery. He helped to complete what Dr. Lloyd had begun, and had the satisfaction of witnessing the good results of their mutual efforts.

He was one of the petitioners for the incorporation of the Massachusetts Medical Society, and in 1798 became its president. In 1804 he delivered the annual discourse on Phthisis Pulmonalis. He died September 11, 1822.

Dr. John Jeffries graduated at Harvard College with its first honors in 1763, and immediately began his medical studies under the direction of Dr. Lloyd. He afterwards went abroad to perfect himself in his profession, and placed himself under the tuition of eminent physicians in England and Scotland. He attended several courses of lectures on the theory and practice of midwifery by Dr. Colin McKenzie. The University of Aberdeen conferred on him the degree of Doctor of Physic, and he was the first native of the American Provinces who obtained that honor.

He returned to Boston, and entered upon his professional labors. The Revolution came and found him a royalist. When the British evacuated Boston he went too. He served as surgeon in the British army and navy, and afterwards practiced his profession in London. He became interested in midwifery, and at one time thought of confining his attention to this branch. From this, however, he was dissuaded.

He was interested in scientific investigations. He made two aerial voyages, in one of which he crossed the British Channel from Dover to France. From these voyages he gained some reputation and more notoriety.

He once more returned to Boston, in 1790, and resumed practice. He became eminent as a physician, obstetrician, and surgeon. He attempted to give a course of lectures on anatomy, but a mob gained possession of his subject, and carried it off in triumph. He took special interest in midwifery, and left on record nearly two thousand cases of labor. He died in 1819, aged seventy-six years.

¹ Among these may be named the venerable Dr. Edward Reynolds, to whose kindness I am indebted for several facts in relation to Dr. Lloyd.

Dr. Oliver Prescott was another of Dr. Lloyd's students. He was born in Groton, and began practice in his native town. He removed, in 1811, to Newburyport. He delivered the annual discourse of 1813 before the Massachusetts Medical Society, on the Natural History and Medicinal Effects of the *Secale Cornutum* or Ergot. Dr. Prescott was one of the first to suggest the use of this drug to American physicians, and he carefully studied its effects. His discourse was very favorably received, was reprinted in Philadelphia and London, and was translated into the French and German languages.

Dr. Marshall Spring, of Watertown, graduated at Harvard College in 1762, and a few years later settled as a physician in his native town. He became the most famous doctor in the neighborhood. His house, especially on Sundays, was thronged with persons seeking professional advice. We may infer that his obstetrical practice was large from the fact that in 1776 such was his notorious torquism he would have unquestionably been sent out of the country, "if the exigencies of the ladies had not prevented."

Dr. Moses Little deserves mention as an obstetrician of good reputation. He practiced in Salem at the beginning of the present century, and was celebrated as a surgeon and accoucheur. In the year 1808 he was present at the births of precisely one half of all the children born in Salem during the year. He died of phthisis. His wife had died a few years before of the same disease. He wrote for himself the well-known epitaph: "Here lies the body of Dr. Moses Little, who died about forty-five years old."

Phthisis insatiabilis!
Patrem matremque devorasti —
Parce O parce liberis."

Dr. Thomas Kast, the son of a physician, began his medical studies under the care of his father, spent two years in England, where he studied practical midwifery under Dr. Mackenzie, and settled in Boston in 1774. He was an able man, and had a large obstetrical business.

Dr. James Lloyd and his contemporaries, several of whom were his pupils, rendered a service to the art of midwifery which should be gratefully acknowledged and remembered by the medical profession.

We have now reached the close of the second century of our obstetrical history. During this period the practice of midwifery has been gradually passing from the hands of incompetent women to the charge of educated physicians. And it is a noteworthy fact that during these same two hundred years there was a signal improvement in the practice of this branch. It appears from the mortality bills of London, that for twenty years ending in 1680, one in every forty-four delivered died, while for twenty years ending in 1820, only one in every hundred and seven died, so that the number of parturient mothers lost during the last years of the seventeenth century was about double the number lost during the first years of the nineteenth century. It is perhaps fair to infer (although we have not the statistics at hand to prove it) that a similar improvement took place in other cities and large towns.

The medical department of Harvard University was organized in 1782. In November, 1815, Walter Channing was announced as the first professor of the theory and practice of midwifery.

No doubt midwifery had been taught in the Medical School to a certain extent during the thirty years pre-

ceding Dr. Channing's appointment. The professors of anatomy and of the theory and practice of medicine would naturally give a few lectures upon it in their annual courses. But it had evidently been considered a subordinate branch.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

THE ARNOLD ARBORETUM.

NOVEMBER 14, 1881. DR. T. B. CURTIS presided. The meeting being called to order, the chairman stated that a petition to the city government requesting its acceptance in behalf of the city of Boston of the Arnold Arboretum as offered for a park by Harvard College was awaiting the signatures of the members. The chairman requested Dr. Williams to say a few words to the Society in regard to the advantages of the arboretum as a park. In compliance Dr. Williams entered upon some details concerning the character of the arboretum itself, describing its situation and surroundings, the beauty and extent of the views from the more elevated points, the facilities afforded by a running brook for artificial bodies of water, the pleasure and instruction offered by the beauty and variety of the trees, a large number of which are already well grown. Dr. Williams then reverted to the extremely favorable terms of the offer made by Harvard College, and to the very small outlay and annual charge for which the city of Boston had the opportunity to make so desirable an acquisition. Dr. Williams's remarks closed with an allusion to the enigmatical apathy of some of the members of the city government in responding to the offer of the college, an allusion which seemed to express the sentiment of the Society.

PYEMIA.

DR. F. MINOT read a paper entitled *A Case of Pyæmia with Obscure Origin*. Vide page 485 of the JOURNAL.

DR. H. I. BOWDITCH inquired if an examination of the blood had been made to see if there was pus in the blood, and questioned the propriety of calling the disease pyæmia unless there was evidence of pus in the blood.

DR. MINOT replied that no examination of the blood had been made.

DR. GOSS referred to a case somewhat similar to that of Dr. Minot's, reported by Dr. Cook before the Massachusetts Medical Society.

DR. E. G. CUTLER said that Dr. Minot's case resembled one reported by Dr. Cook before the Massachusetts Medical Society a year and a half ago. The heart and large vessels were carefully examined for evidences of ulcerative endocarditis, but nothing of the sort was found. Similar cases had been reported in Germany, one observer having met with no less than six. In the report on pyæmia to the Pathological Society of London about a year ago these cases were included in a distinct class.

DR. FITZ suggested the view that the case may have been primarily one of rheumatic arthritis, and that the infective element was later introduced through the abscess near the toe.

The various cases of infective osteo-myelitis and

periostitis reported within the past few years suggested the possibility that infective material might even be brought into the body without any obvious external wound. The hypothesis that the respiratory and intestinal tracts might serve as channels for absorption under such circumstances had been presented, and was not without evidence in its favor.

It did not seem necessary to demand a common local origin for the abscesses in the case reported. Although the condition of the lungs indicated a probable embolic affection, it was not equally probable that the mammary abscesses were of like origin. There was no sufficient evidence of a source for arterial embolism, and it seemed highly improbable that emboli of venous origin, of sufficient size to produce such disturbances, could have passed through the capillary plexus of the lungs.

The axillary abscesses in turn were directly attributable to the suppuration in the mammae, through the medium of the lymph circulation, and did not demand an embolus as a cause.

The case was an exceptional one in many respects, and as one of pyæmia could not be exclusively classified under any one of the sub-divisions usually recognized.

DR. CHEEVER said that he had seen cases in children which he had supposed to be pyæmia, though not proved by autopsies, caused by fractures and bruises.

In these cases no cause of infection could be discovered, and the patients died after some weeks with symptoms of pyæmia.

Dr. Cheever also referred to a case reported by Dr. Hodges some years ago, where a boy, while sliding down hill, received a blow on the nates, without any open wound or abrasion, and yet symptoms of pyæmia followed, and death ensued.

In none of these cases was there any abscess at the seat of injury. Dr. Cheever supposed it possible that some change from injury to the veins, from the blow, might take place, followed by the formation of thrombi and their subsequent detachment.

to do is already answered in part, — more in detail, — he gives first the anatomy of each portion of the nervous system beginning with the brain. This anatomical review is not exhaustive, that could not be expected, but it is sufficient for understanding the physiological and clinical sections which follow. The account of the functions of the different parts of the brain is given with reasonable fullness, and is followed by a section upon the surgical bearings of cerebral topography. The part devoted to the brain closes with sections upon the clinical subdivisions of the brain and a summary of the physiology of the cortex, and the effects of disease located in that portion of the cerebrum.

This will perhaps sufficiently indicate the plan of the work. The same general plan is followed in regard to the other divisions of the nervous system. There is very little to criticise in the execution of this plan, and the descriptions are reasonably good. Only a few minor errors are to be found, which are not worth mentioning. The illustrations are partly original and partly derived from a variety of sources, and are very important aids to understanding the text. The book is especially valuable as bringing together in convenient relations facts and inferences which aid greatly in forming correct diagnoses in nervous disease.

Indigestion, Biliousness, and Gout in its Protean Aspects. Part I. Indigestion and Biliousness. By J. MILNER FOTHERGILL, M. D. New York: D. Appleton & Co. 1881.

Dr. Fothergill has produced a very readable, if not a very original, book on subjects concerning which the last words are very far from having been spoken. Advances in physiology and chemistry necessitate a frequent revision of theories concerning the digestive processes and the causes of mal-assimilation.

The present volume, or part first of the subjects embraced by the title-page, offers a chapter on natural digestion; three chapters devoted to primary indigestion; two chapters on secondary indigestion, under which head in the first are included neuro-sal, reflex, cardiac, and toxic indigestion, the second considering indigestion as an intercurrent affection; the next chapter treats of diet and drink; and the remaining four of the functions of the liver, and the phenomena of liver disturbance with its medicinal and dietetic treatment.

The volume closes with an appendix on the failure of the digestive organs at the present time which draws rather a gloomy picture of the future, if in truth there be any for the Anglo-Saxon race on both sides of the Atlantic unless some radical changes ensue in the nourishment and rearing of infants. The author's prophetic eye sees the disembodied spirits of Indian braves gloating over the summer mortality tables of our cities, and dancing a retributive war dance over the graves of the little victims of diarrhoeal diseases.

Dr. Fothergill's ready pen has served him well in setting forth what he has wished to say about the subjects embraced in his book, and he has shown good judgment in selecting freely and with due acknowledgment from the materials of other writers. The chapter on suitable forms of food owes much to Dr. Wm. Roberts, and those on the liver and its disturbances to Dr. Murchison. Lithæmia and the lithic acid diathesis receive attention in these chapters on the liver,

Recent Literature.

The Applied Anatomy of the Nervous System, Being a Study of this Portion of the Human Body from a Standpoint of its General Interest and Practical Utility, designed for Use as a Text-Book and a Work of Reference. By AMBROSE L. RANNEY, A. M., M. D. With Numerous Illustrations. New York: D. Appleton & Co. 1881. Pp. xxvii., 500.

This is a useful book, and one of a novel design. In brief the object has been to include in one volume the anatomy and physiology of the nervous system, at least so much of these as may be necessary to explain the clinical points depending upon these two departments. There is no complete description of diseases, pathology and treatment and ætiology are either entirely omitted, or only incidentally referred to when thereby the chief object of the book can be promoted.

The author says in his preface that "it is not to be expected that many points stated in the physiology, symptomatology, or even in the anatomy will not be open to discussion, and, possibly, to contradiction." This might be said of almost any department of medicine.

The question as to what the author has undertaken

and will probably come in for a share of discussion more proportionate to their present popularity in Part II., which will treat of gout in its protean aspects.

On the Antagonism between Medicines and between Remedies and Diseases. By ROBERT S. BARTHOLOW, M. D., LL. D. New York: D. Appleton & Co. 1881.

This work, which is a compilation of six lectures delivered at the expense of the Cartwright fund, was first presented in writing in the *New York Medical Journal* for January and February, 1881, and is now reproduced as a separate memoir.

These lectures present the antagonism of certain drugs, for instance, as between atropia and physostigma, pilocarpin, quinia, aconite, phytolacca, muscarin, and bromal-hydrate; chloral with strychnine, prototoxin, and atropia, as well as that most commonly known antagonism between opium and belladonna. Then, following the lead of other recent therapeutical writers, he presents the view of drugs which antagonize certain physical functions, such as that of cardiac pulsation and respiratory movements, also the antagonism of drugs to inflammatory processes, with an explanation on this basis of their selective action. This kind of therapeutical literature is, in our opinion, very valuable to the progress of scientific medicine, and we sincerely hope that such original workers as Professor Bartholow will continue in the field of experimental therapeutics, and push the study of physiological action of drugs as far as possible.

We cannot do better in presenting the character of the present work than by copying a few sentences from the lecture of "Antagonism between Remedies and Diseases." "As respects diseases of particular organs, we find that antagonism is exerted in two modes. . . . The antagonism by similarity is the action of the remedy on the same tissue, and with similar objective signs; but the effect on the tissue is opposed, for the disturbance produced by the remedy must necessarily be different in kind from that produced by the disease. . . . In the treatment of inflammation we have an illustration of how the successive steps in the development of the process are in turn subjected to the action of opposing agents. As this process enters largely into the structural alterations produced by disease, we are thus encouraged in our efforts to obtain results by the application of the law of antagonistic action."

The Harrowgate Waters, Data Chemical and Therapeutical, with Notes on the Climate of Harrowgate. By GEORGE OLIVER, M. D., Member Royal College of Physicians of London, etc. London: H. R. Lewis. 1881.

This memoir contains a description of an English inland watering-place having an elevation of between 400 and 600 feet above sea level, very favorably situated for a dry and stimulating climate, meteorological observations for ten years showing that only an annual average of 156 days are rainy, while at Leamington, also an inland town, this average is 169 days, and at Torquay, by the seaside, this average is 190 days. The mortality rate among the residents of Harrowgate is

only 12.1, whilst, including also the population and the number of temporary visitors, it is only 16.5 per 1,000; the author calls attention to the fact that these "visitors are, as a class, more ailing than such as resort to seaside and other watering-places merely for recreation."

The contra-indications to a residence (especially in the cold months) in this town are chronic pulmonary disease, progressive organic disease, irritability of mucous membranes, and a highly sensitive and irritable state of the nervous system. Dr. Oliver describes the mineral waters of Harrowgate as like those of Homberg, Kissingen, Kreusnach, etc., that is, "non-thermal," but by an artificial contrivance the sulphurs, Kissingen, and chloride of iron waters are warmed and served at any desired temperature. The chemical constitution of the Harrowgate waters is given in detailed table form. Our author presents all these, as well as the therapeutical points, most faithfully, and if we could receive similar information about other natural springs the result would prove of immense value to our profession.

These waters are classified as follows: 1st, Sulphur; 2d, saline sulphur; 3d, iron; 4th, saline chalybeates; 5th, sulphated chalybeates.

Hydrophobia. By HORATIO R. BIGELOW, M. D. Philadelphia: D. G. Brinton. 1881. 1 vol., 8vo, pp. 154.

This is a monograph intended for the profession and the public. The author's aim has been to embody in compact form the literature pertaining to the subject of hydrophobia, and he does not profess to offer any original investigations. The literature of the subject is unquestionably very extensive and widely scattered, but the author, living in Washington, has certainly had in the library of the Army Museum unusual facilities of access to it, and he has succeeded in condensing a great deal into the space at his command. The final chapter on the most recent views of the pathology and treatment might perhaps have been lengthened with advantage so as to include a fuller reference to the observations of Drs. Gowers and Coats, verified by those of Dr. R. H. Fitz in this country.

The book may be consulted with advantage by those wishing to get a general idea of what has been written upon the subject of hydrophobia.

Dyspepsia and How to Avoid It. By JOSEPH F. EDWARDS, M. D. Philadelphia: Presley Blakiston. 1881.

Starting with the premise that the majority of cases of functional derangement of digestion are due to defective rules of eating, Dr. Edwards has written another primer, which he thinks will convince those readers who follow it to the end that very few persons know how to eat; at the same time, however, he promises to counteract the effect of this depressing discovery by teaching them how they ought to eat. We do not doubt that any one both willing and able to carry out all the good rules and wise counsels given by the writer without thinking too much of his internal processes will not regret the purchase and perusal of this primer.

Medical and Surgical Journal.

THURSDAY, NOVEMBER 24, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter.

HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

EPIDEMIC CONVULSIONS.

MATERIALS for a "Medical History of Kentucky" had been collected by the late Dr. Yandell, of Louisville, and among them his son, Dr. L. P. Yandell, found some which he has put together in the form of a paper on epidemic convulsions in the last number of *Brain*. This paper recalls vividly the very peculiar religious and social phenomena which presented themselves in the then Western States and territories at the beginning of this century, and were nowhere so extravagant as in Kentucky and Tennessee. The outward and visible process of conversion or "getting religion" under strong mental excitement and emotional stimulants has exhibited itself at different epochs and in various countries, and the resulting phenomena, when divested of supernatural signification, have been shown to be susceptible of pretty accurate analysis and no-ological classification. Dr. Felix Robertson, of Nashville, Tennessee, published in Philadelphia, in 1805, an essay on chorea, devoted to a study of the same extravagances of early Methodism in the States above-mentioned. His description of the religious influences which favored these outbreaks is very graphic. "I suppose," he says, "there are but few individuals in the United States who have not at least heard of the unparalleled blaze of enthusiastic religion which burst forth in the Western country about the year 1800, but it is, perhaps, impossible to have a competent idea of its effects without personal observation. This religious enthusiasm traveled like electricity, with astonishing velocity, and was felt almost *instantaneously* in every part of the States of Tennessee and Kentucky. It often proved so powerful a stimulus that every other entirely lost its effect or was but feebly felt. Hence that general neglect of earthly things which was observed, and the almost perpetual attendance at places of public worship. . . . At these meetings many remained on the spot the whole or the greater part of four or five days worshipping their Maker almost incessantly. The outward expressions of their worship consisted chiefly in alternate crying, laughing, singing, and shouting, and at the same time performing that variety of gesticulation which the muscular system is capable of producing. It was under these circumstances that some found themselves unable by voluntary efforts to suppress the contraction of their muscles. . . . The disease no sooner appeared than it spread with rapidity through the medium of the principle of imitation. . . . It attacks

both sexes and every constitution, but evidently more readily those who are enthusiasts in religion and females; children of six years of age and adults of sixty have been known to have it, but a great majority of those affected are from fifteen to twenty-five. The muscles generally affected are those of the trunk, particularly of the neck, sometimes those of the superior extremities, but very rarely, if ever, those of the inferior. The contractions are sudden and violent, such as are denominated convulsive, being sometimes so powerful, when in the muscles of the back, that the patient is thrown on the ground, where for some time his motions more resemble those of a live fish when thrown on land than anything else to which I can compare them."

In the novel called *The Circuit Rider*, whose author, himself at one time a preacher, had traveled through these States, and the scene of which is laid in Kentucky at this period or a little earlier, the same nervous disorders are frequently referred to. On one occasion a recalcitrant young unbeliever at a meeting is thus apostrophized by the earnest evangelist: "Young man," roared the preacher, "you are hair-hung and breeze-shaken over that pit that has no bottom!" At another stage of the story a scoffing uncle is being exhorted to repentance at a meeting by a lately-converted nephew, with the following result: "He listened a minute to Kike's exhortation, and the contrary emotions of alarm at the thought of God's judgment and anger at Kike's impudence contended within him until he started for his horse, and was seized with that curious nervous affection which originated in these religious excitements and disappeared with them. He jerked violently, his jerking only adding to his excitement, which in turn increased the severity of his contortions. This nervous affection was doubtless a natural physical result of violent excitement, but the people of that day imagined that it was produced by some supernatural agency, some attributing it to God, others to the devil, and yet others to some subtle charm voluntarily exercised by the preachers. Lumsden went home jerking all the way, and cursing the Methodists more bitterly than ever."

Dr. Yandell, quoting from McFerrin's *Methodism in Tennessee*, says of Granade, a celebrated preacher of this period. He was a stormy orator who drew great crowds wherever he went; his person was commanding, and with a sounding voice and most impassioned manner, his oratory produced startling effects; so violent was his manner that he often broke down the stands erected for him in the woods. Of the results of this oratory Granade himself says that at one of his meetings the people fell as if slain by a mighty weapon, and lay in such piles and heaps that it was feared they would suffocate.

As an example of another kind of influence potent at the period, as "another feature of these excited meetings, which served still further to intensify the feelings of the people who attended them for days and nights together," Dr. Yandell refers to the part taken in them by the children, and illustrates it again from

McFerrin. Thus a boy who appeared to be about twelve years of age is described as having retired from the stand at Indian Creek, Ohio, during the sermon, and mounting a log, and raising his voice to a high pitch, soon had nearly all the congregation with him. A man on each side held the boy up and he spoke for about an hour. When quite exhausted, and language failed to give utterance to his emotions, the little orator raised his hands, and dropping his handkerchief, wet with tears and perspiration, cried out, "Thus, O sinner, shall you drop into hell unless you forsake your sins, and turn to the Lord." At that moment some fell like those who are shot in battle, and the work spread in a manner which human language cannot describe.

Influences like these acting upon a simple and self-concentrated people, which even affected the robust and vigorous, were sure to produce a variety of nervous disorders among the weaker and more superstitious portions of the community. The form which these disorders most frequently took was called by the people themselves the "jerks." It has been already referred to in the quotation from The Circuit Rider, and was evidently choreaic in character. In the paper in *Brain* they are spoken of thus: The jerks, as they were termed, presented some novel and remarkable features. The first form in which these spasmodic movements made their appearance was that of a simple jerking of the arms from the elbows downward. When they involved the entire body they are described as something terrible to behold. The head was thrown backward and forward with a celerity that alarmed spectators, causing the hair, if it was long, to crack and snap like the lash of a whip. Sometimes, says the Rev. B. W. Stone, the subject was affected in a single member of his body, but at others the spasms were universal. When the head alone was affected it would be jerked from side to side so quickly that the features could not be distinguished. When the whole system was affected, he continues, I have seen the person stand in one place and jerk backward and forward in quick succession, the head nearly touching the floor behind and before. All classes, saints and sinners, the strong as well as the weak, were thus affected. I have seen some wicked persons thus affected, and all the time cursing the jerks while they were thrown to the earth with violence.

Another writer, an eye-witness, says of the "jerking exercise:" Nothing in nature could better represent this strange and unaccountable operation than for one to goad another alternately on every side with a piece of red-hot iron.

But the "jerks," though the most frequent, were by no means the only phenomena. These disorders, Dr. Yandell tells us, assumed many other grotesque forms besides those which have been described. The subject often rolled over and over on the ground or ran violently until worn out with exertion. Hysterical laughter was another modification. Instances of laughter were only occasional at first, but it grew, until in 1830 the "holy laugh" was introduced systematically as a part of religious worship. Sometimes

half the congregation, apparently in the most devout spirit, were to be heard laughing aloud in the midst of a lively sermon. As the excitement grew the infatuated subjects took to dancing, and at last to barking like dogs. Such were called the *Barkers*, and it was supposed they wished to indicate by their outward form the degradation of their human nature.

We learn from a reliable witness that so late as 1858 he himself had seen thousands of people affected by the "Avoca jerkings," under the influence of exciting preaching in Central Illinois.

The various nervous disorders described by eye witnesses and historians of the period may be classed according to the phenomena observed as sympathetic hysteria, chorea, or imitative epilepsy, and recall similar outbreaks among other people in other countries at different periods under the influence of strong religious excitement, though it may be questioned whether the epidemic form has ever been so marked and widespread as it was in Kentucky and Tennessee, or the results quite so extravagant. The nervous phenomena coincident with the different phases of the dancing mania in Europe in the Middle Ages, with the career of the Camisards and Convulsionnaires in France, with the gloomiest period of Presbyterianism in Scotland, with the Jumpers in England, with the dancing and howling dervishes among Mohammedans, and within a few years those exhibited in outbreaks among superstitious villagers in the mountain districts of France and Italy, all these phenomena belong to the same class of affections as those accompanying the spread of early Methodism during the first years of this century and the latter half of the last in parts of this country. They present an interesting field for the cultivation of the neurologist and one which may be made more profitable to him than to the theologian, and, as we have said, nowhere were there more surprising exhibitions of these disorders than in Kentucky.

As to the nature of the phenomena, as there observed, Dr. Yandell draws the following conclusions:—

The convulsions once started in a congregation spread quickly through it, until all the fit subjects were convulsed. Repetition greatly increased the proneness to the disorder, which was invited by the masses on the supposition that it was a true religious exercise.

The everted muscular movements all come under the head of morbid reflex action. By the continued religious fervor the central portions of the brain, the immediate seat of emotion and feeling, became inordinately excited. The impression transmitted downward to the spinal cord threw the muscles of voluntary motion into convulsions. Sensibility, which has its seat in the sensory ganglia, was generally annulled. When the hemispheres became involved the subjects fell into a state of unconsciousness or coma. In this abnormal condition of the nervous centres, the bare recollection of the distressing scenes was sufficient in many cases to excite the convulsive movements. The former belong to sensori-motor actions; this last is an example of ideo-motor movement; instances of which are afforded by the act of vomiting, which may be

caused by the recollection of disgusting sights or odors. The principle of imitation accounts for the rest. The great nervous centres, in multitudes of people, being in a state of polarity, any unusual exhibition of feeling would throw the more excitable into spasms; and the affection would then spread by sympathy, as hysterical convulsions and chorea are known to spread among girls at boarding-schools. And as fear has checked these, the epidemic convulsions were checked by reason and common-sense, and finally ceased under the law which limits all violent action.

THE ARNOLD ARBORETUM. IS IT TOO CHEAP FOR A PARK?

THE timely remarks of Dr. H. W. Williams before the Medical Improvement Society remind us that among the many park schemes which have been proposed for the city of Boston during the past ten years, the Arnold arboretum is conspicuous as the only offer of assistance which has been made to the city treasury from outside parties.

It is assumed that parks make any city more healthy and attractive, the only question which seems to trouble the minds of the present city fathers is whether they can afford such desirable luxuries, and in considering this they do not seem to have given full weight to the advantages which the arboretum would offer.

Under the will of the late Benjamin Bussey Harvard College obtained a gift of some two hundred acres of land in West Roxbury, on which they were required to establish "a course of instruction in practical agriculture, in useful and ornamental gardening," etc., and a considerable endowment was made by the same will to found the Bussey Institution for this purpose.

Some years later James Arnold, of New Bedford, left a sum of money, which was given to the president and Fellows of Harvard College for the purpose of founding "the Arnold Arboretum, which shall contain as far as is practicable all the trees, shrubs, and herbaceous plants, either indigenous or exotic, which can be raised in the open air at the said West Roxbury."

Harvard University now receives an income from this fund of about eight thousand dollars a year, which is devoted to the purposes named and to the salary of a professor of arboriculture, who is also curator of the grounds, and from the two hundred acres of the Bussey estate they have set aside a tract of some one hundred and twenty acres for the arboretum.

The proposition at present is for the city to take all this one hundred and twenty acres, and to buy in addition some forty-eight acres of adjoining property which shall also be used for the purposes of the arboretum, to lay out a driveway through the property, and to supply a sufficient police force to protect it.

The college agrees on its part to allow the city to take the one hundred and twenty acres with the exception of some twenty acres reserved for nurseries, etc., without making any claim for damages; it agrees to maintain the grounds, trees, etc., without expense

to the city, and to throw the whole arboretum open to the public under such regulations as will prevent willful damage; in other words it really agrees to give the city one hundred and twenty acres of land for nothing, and to bear the larger part of the cost of developing and beautifying the property.

It is estimated that the cost of purchasing the additional forty-eight acres of land would be sixty thousand dollars; to this must be added the cost of laying out the roads, seventy-four thousand dollars, which with water pipes, sanitariums, etc., would make a total of say one hundred and fifty thousand dollars; beside this the annual cost of police and care of roads would be something like ten thousand dollars a year.

It has been objected that the arboretum will not supply the place of a true park, since there will be no place for athletic games and picnic grounds, that the expense of the driveways will be very great, and that the plan will be for the advantage of the college rather than the city.

On the contrary, twenty-two acres are to be reserved for a recreation ground, where the great public can picnic to their hearts' content. As to the cost of driveways, *this is the first estimate which has been made in any of the park schemes of the probable expense to which the city will be put in order to develop the property*; it is not in itself excessive, but if the same figuring was to be applied to the other and larger territories, which it is desired to take, it would make a bill such as even the boldest alderman would shrink from. The last objection is easily answered by the statement that the college already has the one hundred and twenty acres of land and an income of eight thousand dollars to develop it; it does not require a grant from the city in order to establish the arboretum, for that is already established; it merely says, We cannot afford with our present means to open our grounds freely to the public, for our income must be spent in developing the Arboretum and we have no money for police or for constructing roads, but if the city will assume this expense we will open our grounds freely to the public and will show them a museum of forestry such as does not exist elsewhere in the country, and which in the course of a few years will be attractive, not only on account of its natural beauty, but which will be a most instructive park in calling to public notice all the possibilities of forest culture in our changing climate.

By all means let the city have lungs, and good ones, with plenty of air space for breathing, under any circumstances, but especially when the performance of the pulmonic functions can be secured for a very moderate outlay. And when such an offer as this is made, we hope that the good sense of the city fathers will lead them to accept it.

MEDICAL NOTES.

— A woman has been fined five pounds and costs in Liverpool for letting a house which had been tenanted by a family in which there had been scarlatina, but which had not been properly disinfected afterwards.

— In the current number of *Brain*, Dr. Alexander James, Lecturer on the Institutes of Medicine in Edinburgh, states that the experiments designed to illustrate his paper on the Reflex Inhibitory Centre Theory, were, owing to legislative enactments and official obstruction in England, performed on the continent, under rather disadvantageous circumstances, at the beginning of last summer session. The experiments involved the sacrifice of a few frogs, probably not more than half a dozen, and have a direct practical bearing on our interpretation of the symptoms of disease, besides more remote relations of great significance.

— Professor Max Müller has been unanimously elected Curator of the Bodleian Library, in the vacancy occasioned by the decease of Professor Rolleston, F. R. S.

— The total number of persons in receipt of public relief in Paris last year was 385,148, of whom 137,518 were received in the hospitals, almshouses, and orphanages; while 219,500 were relieved at their own homes, and 28,000 children put out to nurse in the country.

— Dr. Foulis, of Glasgow, died on the afternoon of October 31st from a severe attack of diphtheria, contracted, it is feared, while performing the operation of tracheotomy on a patient suffering from the affection. Although a comparatively young man, Dr. Foulis had already made his mark, both in pathology and in the special branch of surgery which he had taken up, namely, affections of the throat. His successful cases of extirpation of the larynx had given him world-wide celebrity. In Glasgow, he was regarded as one of the most rising men in the profession.

— Dr. Alfred H. McClintock, of Dublin, who presided at the Section of Obstetrics at the late International Medical Congress, died last month quite suddenly of heart disease at the age of sixty.

— United States Consul Heap, at Constantinople, reporting to the department of state relative to the appearance of cholera at Aden and Mecca, refers to the adoption of sanitary measures heretofore published, and says: "The plans proposed having been deemed inadequate by the Sultan, an order was issued convening the council of health at once, and directing the issue of a decree requiring that all arrivals from infected countries shall be subjected to a long quarantine at a suitable locality outside the straits of the Mediterranean (Dardanelles). The city of Constantinople is in bad condition. Vast quantities of filth, the accumulations of years, are to be found in the heart of densely inhabited quarters. The location of the city, however, is such that, with its ample water frontage and deep and rapid current of the Bosphorus, it should be one of the best drained cities in the world. On the contrary, it is one of the worst, and it is doubtful whether the authorities will be able to place the city in such a condition as will prevent an epidemic of cholera in case the disease makes its appearance. What has been said of the condition of Constantinople is true of all the cities and towns of Turkey. Many of them, indeed, are in worse condition, and when the pestilence starts up on its march northward, there

will be no lack of food upon which it can feed and grow.

— The Forfarshire Medical Association had under consideration at a recent meeting, and for the purpose of promoting uniformity of practice amongst its members in their management of infectious fevers, the questions of period of incubation and duration of infectiveness, and they decided to adopt for practical purposes, and without going to extremes, the following periods of incubation: For small-pox, typhus, whooping-cough, measles, fourteen days; scarlet fever and diphtheria, eight days. Convalescents from these fevers should be considered as still liable to give off infection until the expiry of a period of time, counting from the beginning of the illness, ranging for each fever as follows — whooping-cough eight weeks, scarlet fever seven weeks, measles six weeks, diphtheria six weeks, typhus four weeks, small-pox fourteen days after disappearance of scabs. — *Lancet*.

Miscellany.

OBITUARY: WILLIAM FURNESS JENKS, M. D.

At the November meeting of the College of Physicians of Philadelphia, the death of Dr. William F. Jenks, on the 31st of October, 1881, was announced, and the secretary was directed to transmit the appropriate resolutions to his bereaved family.

Dr. Jenks was born May 15, 1842, and consequently was in his fortieth year when he succumbed to the disease which had been undermining his strength for the last seven years. Graduated at Harvard in 1863, and three years later (1866) at the Department of Medicine at the University of Pennsylvania, he subsequently studied abroad in Berlin, Vienna, London, and Edinburgh, paying especial attention to obstetric medicine. In 1870 he returned to Philadelphia and engaged actively and enthusiastically in medical practice and in teaching. He organized the obstetrical department of the Philadelphia Dispensary, and for several years worked very faithfully in connection with it. He associated himself with the Chant Street medical organization, situated in the rear of the old University buildings, and took great interest in lecturing and quizzing students. In the Pathological and Obstetrical Societies of Philadelphia he was an active and valued member. In 1871 he was elected a Fellow of the College of Physicians, and in 1874 was appointed to prepare a course of lectures under the Müller bequest. These lectures were never delivered. An insidious disease, against which he had been manfully struggling, now became painfully evident, and the sad fact became known to his friends that he was doomed, a victim to pulmonary consumption. The course of lectures that he had outlined on a subject connected with the pathology of the pelvic organs in the female was never more than projected; his teaching was abruptly discontinued, his literary work ceased; his main object in life now was the care of his health, living a very retired existence with his little family, and he certainly prolonged his life for several years by travel and wisely husbanding his strength. When his health finally broke down, in 1874, he gave up a position in which he had become widely known, that of editor of the *American*

Supplement to the *Obstetrical Journal* of Great Britain and Ireland, published by Mr. Lea, the duties of which he had performed with much credit for several years. He was also surgeon to the State Hospital for Women, a charity in which he was warmly interested; this position he retained up to the time of his death.

Dr. Jenks was of slight frame, nervous, and quick in his movements, and was equally quick in his mental processes. A man of culture, of charming address, a good lecturer, ever ready to explain to students, his zeal and ability were only limited by his physical strength. Rapidly rising in his profession, his superiority was acknowledged, and he had already become so prominent in 1872 that he was elected a delegate to the American Medical Association which met in Philadelphia in that year, and of which he was a permanent member at the time of his death. The Simpson forceps were introduced into this country by Dr. Jenks, and mainly through his advocacy have the profession here been led to appreciate their merits. His contributions to medical literature are principally found in the transactions of the Societies to which he belonged and in the first two volumes of the American Supplement to the *Obstetrical Journal*; they were not numerous nor pretentious, but they uniformly exhibited marked ability. He also contributed to other journals, for instance, a very able review of Schroeder's Midwifery in the *American Journal of the Medical Sciences*.

Dr. Jenks married the daughter of John H. Towne, who is widely known as the generous founder of the Towne Scientific School of the University of Pennsylvania. Two children resulted from this union, both of whom are still living at Jenkinstown, near Philadelphia, where their father died. Thus ended in seclusion and comparative inactivity a life at one time so full of promise that all the rewards and honors of the profession seemed in immediate prospect. After years of toil and faithful preparation Dr. Jenks, in the midst of success, was compelled to relinquish every hope, summoned to lay down his life-work ere it was scarcely begun. Truly says the philosopher, "All through the life of a pure-minded but feeble-bodied man his path is lined with memory's grave-stones, which mark the spots where noble enterprises perished for lack of physical vigor to embody them in deeds."

PROFESSOR BOUILLAUD.

Professor Bouillaud died in Paris October 29th, at the age of eighty-five. His father was a tile maker in a little country village, Bragette. It was through his uncle, who held a medical post in the army, that of surgeon-major, that his attention was directed to the study of medicine. He took his degree in 1823 and was a contemporary and a competitor in the *concours* of the Paris school and hospitals of Velpeau, Trousseau, Piorry, Bernard, and other medical celebrities.

In 1831 Bouillaud gained the professorship of clinical medicine attached to the Charity hospital, and it was then that he made his reputation as a writer and a teacher. His advocacy of repeated and almost universal blood-letting in disease will be recalled by those who followed his clinic. He was the author of several works, the most remarkable of which was that on diseases of the heart, in which he was the first to point out the intimate connection that existed between val-

vular disease and rheumatism; that the former was not a mere coincidence or complication, but that it was one of the most constant manifestations of the rheumatic taint. He interested himself somewhat in politics at one stage of his career, and was twice returned to the Chamber of Deputies, but he was more happy in his professional than in his political contest. Professor Bouillaud was president of the International Scientific Congress held in Paris in 1867. He was a member of the Academy of Medicine, of the Institute, and a commander of the Legion of Honor.

ABUSE OF THE VAGINAL SPECULUM.

A FEW days ago a gentleman in a highly respectable position in society in the north of England called on me for advice in the following peculiarly painful circumstances. He averred that through the use, or rather the abuse, of the vaginal speculum he had lost, as he feared forever, the affection of his wife, who is, I may say, an amiable and accomplished lady. His case interested me so much that I asked his permission to publish it in the *Lancet* [from which we extract]. This he at once agreed to; not only so, but he wrote out a history of it himself, so that I shall for the most part allow him to tell his own story.

No instrument is of more importance to a medical practitioner than the vaginal speculum; still the facts narrated below must impress us with a grave sense of the responsibility which at all times rests upon us in the use of the instrument; and how, without any intention on our part, the peace, the happiness of a household, may be broken up forever. But let the chief, not the only, "victim" speak:—

"I was married to a charming woman. Our happiness continued fifteen years. She became the mother of a family. Then some little ailment set in, which was described to me as a simple case of ulceration. The os uteri was touched with nitrate of silver very frequently during a period of three months, and then she was pronounced completely cured. For that three months I was strictly abstinent. She became warmly attached to her doctor, saying he had saved her life, though he generously enough admitted that it was only a common case, and that her life never was in danger. Then, as time wore on, there were more ulcerations, more examinations, and all the rest of it; accompanied by periods of abstinence on my part, one of them lasting about nine months. During the period of this treatment I, in some unknown way, lost my wife's love. She seemed never happy unless when from home and seeking after advice, which she had from half a dozen doctors. I put my foot down at length on one of her proposed arrangements, and then for several years there was a vacuum, which was ultimately filled by another, and non-medical, influence, that induced her to leave my roof, and resolve on final and permanent separation. Thus the social ruin of a large family—of daughters and sons—seems due to the use of the speculum, and the estrangement caused by the injunctions of 'ladies' doctors, which, I am told, they never impose upon themselves."

Such is my patient's narrative. To all appearance the lady is in the best of health, though, professionally, I have not seen her. What is my patient to do? For the sake of his family he is very unwilling to expose them in a law-court. He has tried to win back his

own and her love and affection. He ascribes the origin of all his trouble, rightly or wrongly, to the speculum and abstinences. We know from experience that when the use of it, or the catheter, is continued for some time to nervous, hysterical ladies a morbid craving for its continued use is created; and therefore we cannot be too discreet in the use of these instruments.

My friend concludes his letter with some practical advice, under four heads, which are indicative of the points on which he makes complaint. To the credit of the profession, I think I may say, the great majority of medical men already act up to them:—

"The instrument may, or may not, be useful, for aught I know; but I maintain: (1) That when it is employed another lady ought to be in the room; (2) that its employment ought not to be continued against the doctor's own opinion merely to gratify a craving, or solicitude, for examinations, which its use has seemed to me to create on an apprehensive, highly-strung woman; (3) that doctors are not at liberty to augment their influence by creating the fear of insanity in such natures by expositions of a near connection between uterine ulceration and the nervous system; and (4) that when a husband's abstinence is imposed its extent should be stated direct to himself, and not merely transmitted through the wife."

These suggestions, especially the first and fourth, will, I think, commend themselves to every member of the profession. By attention to them we avoid even the "appearance of evil."

Perhaps some of your numerous readers would give their advice in reference to the above case in its moral and social, as well as its professional, aspects; and especially as to right professional practice in cases where the speculum is used and abstinence imposed, with the risk, it would seem, of destroying conjugal affection.

Yours truly, M. D.

DR. WILLIAM HUNT ON PRESIDENT GARFIELD'S CASE.

IN a letter to the *Medical News and Abstract* Dr. William Hunt, senior surgeon to the Pennsylvania Hospital, comments upon the case of the late President Garfield as follows:—

"From Dr. Frank H. Hamilton's *Military Surgery*, New York, 1865, page 338, I make the following extract:—

"In a few cases a ball has been known to pass through the side of the body of one of the vertebra, leaving a round hole or a lateral furrow, *without coming in contact with the spinal marrow or the blood-vessels. It is not probable that we shall be able to diagnose such a case clearly during the life of a patient, and if we were able to do so, we do not see what benefit could be derived from any surgical operation.*

"In case, however, one of the transverse processes has been broken and sent inwards, although it is not likely to have penetrated the cavity of the abdomen, it may yet give rise to serious results by the *formation of an abscess in the bellies of the psoas muscles, which abscess may eventually make its way along between the fibres towards the groin, or may empty itself into the loose areolar tissue outside of the peritonæum.*

"The italics are mine. Could there possibly have been a more wonderful foreshadowing of the Pres-

ident's case? The fracture of the transverse process is replaced in the case in hand by the fracture of the body, which produced the abscess or channel along the psoas in precisely the same way as described by Dr. Hamilton. The description is perfect. The sinus or channel which was, in the words of the official report, supposed during life to be the track of the bullet, was practically an abscess and sinus caused by the disintegration of a vertebral body through gun-shot, precisely as a chronic lumbar and psoas abscess is caused by the chronic disintegration of a vertebral body through disease. How truly Dr. Hamilton sets forth the difficulties of diagnosis, and how absolutely true he is as to surgical interference by operation, having for its object the getting of the missile, which, as the autopsy shows, was lying harmless, compared to the injuries it had inflicted. The diagnosis then was hard; but does it not seem, in the light of our present knowledge, that the deep significance of the nervous symptoms of the President immediately after the shooting was lost sight of too early in the case? This, if so, was probably the result of the exciting surroundings, and of the fact that the doctors were more occupied in practical efforts to relieve these symptoms than in speculations as to their cause. They were attributed to injuries or impressions upon nerves of the lumbar plexus, instead of to direct shock to the cord itself. This view seemed to be confirmed by the fact that they promptly subsided under rest and other treatment. That temporary spinal shock does sometimes occur at once after an accident to the column, I will show further on by an actual recent case.

"But those pains in the legs, those 'tigers' claws,' affected *both* sides; what would account for them so well as sudden injury of some kind to the spine? From their bilateral suddenness it is more reasonable to attribute them to direct action upon the centre than to reflex transfer from the right to the left. The right side, I assume, exhibited them to a greater degree than the left, but the full force of the impact was received upon the right and was weakened upon the left. If I am not right, and the pains were equal on both sides, then there is still stronger reason to refer the phenomena to a central origin.

"I have read, also, that at first there was hyperæsthesia of the genitals. If so, this, together with the 'tigers' claws,' pointed strongly to the spine. Some surgeons are skeptical about spinal shock. This summer, in July, Dr. Agnew assisted me in a case that confirms its occurrence.

"A boy was shot in the back to the right of the third or fourth dorsal vertebra. He at once had characteristic symptoms in the legs of being wounded in the spine. These soon disappeared. The course of the bullet was not readily made out at first, but the diagnosis was that the column was wounded without injury to the cord, as the symptoms were not continuous. After suppuration set in, the course of the ball was readily traced with a probe, and broken fragments of the vertebral processes were felt. The ball was not felt with a Nélaton or other probe. The patient was etherized. I made a large and deep incision through the muscles in the line of the wound, and removed some clothing and fragments of bone, and finally a large bullet, which was lying immediately against the bony bridge of a vertebra. The boy recovered. Whether he will suffer from caries in the future remains to be seen. The boy certainly had spinal shock, with-

out injury to the cord, for there was no remnant of paralysis when he was discharged from the hospital.

"But this case is very different from the President's in this, that it was amenable to operation, and we knew about where the ball was. Also here, the ball would have produced great future mischief. In the President's case it did its damage and then hid. If such difficulty occurred in the hunt for it as is stated at the autopsy, imagine the horror of a like attempt on a live man. How long would he have lived? He had better have been killed at a blow.

"The question of the duty of the consulting surgeons when they first went to Washington has been freely discussed. Should they have reopened and re-examined the wound with probes and fingers? I am assuming that they did not do so, and they were right. A hospital chief, if he has confidence in his residents or assistants, and knows them to be experienced and ready, takes what they say about serious cases which will not tolerate officious disturbance. For example, the chief visits the hospital on his regular rounds. The resident says, 'Doctor, here 's a man who was brought in last night shot in the abdomen. He was greatly shocked; I examined him and passed my finger directly into the cavity; I removed some pieces of clothing; I can feel the bullet nowhere under the skin about the whole body; I searched carefully; I have dressed the wound and given some opium; he is now quiet and free from pain.' The surgeon looks at the patient, sees that his general symptoms confirm the diagnosis, and that his wounds are carefully dressed. He probably re-examines the body externally, but if he is a wise man he says practically, 'hands off, we will await results and act accordingly.'

"Many a life has been saved by this course; many a one has been lost by deviating from it. I question if one has ever been saved, in the kind of case now under notice, by deviating from it. Now if a surgeon can so treat those who are *under* him, how much more is he bound (unless he sees something positively and absolutely wrong) to receive the statements of his peers, especially when outward appearances seem to confirm them. I question, moreover, whether any more light whatever would have been thrown on the President's case by further exploration at the time when the consulting surgeons made their first visit? By that time the spinal symptoms had disappeared, or were very much alleviated. Inflammation through swelling of the denser tissues, muscular and fibrous, of the true track of the ball had doubtless closed it. The finger or probes would have passed easily where other fingers and probes had already been, and there would have been almost certainly a positive confirmation of the results of the first examination. When I study the autopsy more closely, I think that this would almost to a certainty have been the case. If I understand the description and the drawing, the ball entered at a place which, if it had had consciousness and an intent to deceive, could not have been better selected in the whole body. It entered 'three and a half inches to the right of the vertebral spines,' therefore its course began to the right of the psoas mass. Instead of going forward, it traversed the circle of the body transversely, after fracturing the eleventh rib, and went directly on in the direction of a chord of an arc of that circle. It entered the post-peritoneal space and thus penetrated the posterior wall of the abdomen without opening the peritoneum. It then continued

on into the muscular mass, separating the longitudinal fibres, which may have closed behind it. The finger was passed into the wound and also probes. These went readily on in the space mentioned, and the true course was missed. I have no doubt the depending liver, or it may be the kidney, was felt. The wound was one to deceive the very elect. The influence of the inner loin muscles in concealing injuries and diseases of the lumbar vertebra is well recognized. The post-mortem report speaks of the dilated track of the ball, but this dilatation was owing to subsequent changes. I am ignorant of any other explanation of the position taken by fingers and probes than that I have given.

"It is a mistake to suppose the spine escaped attention in the case. Dr. Agnew assures me that when he operated for the relief of the lumbar abscess he carefully searched the transverse processes and all of the spine he could feel, and felt nothing wrong. The injury to it was beyond his fingers, and a wise caution here forbade the use of instruments. How truly Dr. Hamilton's remarks are illustrated by this experience. Moreover, by the incisions Dr. Agnew made, which he tells me were carefully planned for drainage, the whole line of the true wound, as well as the mistaken sinns, had full outlet.

"The abscess which was found after death, bounded by the liver, the transverse colon, and the transverse meso-colon, for anatomical reasons, was shut off from communication with the wound, and of course was not drained. In the words of the official report, 'no communication could be detected between it and the wound.' No method of diagnosis occurs to me by which its existence could have been determined during life, unless it had got far enough to cause posterior or anterior bulging. It was an abscess, arising either from peritoneal inflammation through contiguity or it was a septic deposit.

"The case really was one to diagnosticate more by the application of anatomy and physiological and pathological knowledge, than by direct methods. In the light of the autopsy everything is explained. By the theory of the wound during life, almost nothing.

"There were the pains in the limbs and the 'tigers' claws.' There was most profound depression and a pulse and temperature record which, after the liver theory, was abandoned, the accepted wound, at most a severe flesh one, was insufficient to account for. There was the origin of the thoracic duct with its receptaculum chyli right in the line of the wound; hence the rapid emaciation and the other nutritive disabilities, further explained by disturbance of the sympathetic trunks and ganglia. There were the radicles of the vena azygos, bared in the corruption of rotting vertebra, and hence the septicæmia, and there were the abscess and sinus, running toward the groin, a result of the rotting vertebra and not of the ball. What good could it have done to have cut for the bullet after its first mischief? It was then but a small factor in the troubles.

"As to the treatment of the President's case, it was, in the light of the autopsy, most fortunate. A very valuable life was prolonged beyond all reasonable hope. From a letter I had from Dr. Agnew, dated the 23d of August, 1881, which was confidential then but open now, I know how fully he appreciated the profound gravity of the case, and took an almost hopeless view of it, but still he with his colleagues fought it out nobly.

When we come to think of it, it may be a mercy that an exact diagnosis was not made. The temptation to do something more than was done, if it had been made, would have been very great. Outside and inconsiderate pressure would have been clamorous. Whether it would have moved the steady heads in charge, I do not know; but if it had, I am confident the President would have been ready for his grave on the day of the operation. Who can picture the political results that might have followed? Now the perturbing elements have been calmed, and all is peace.

"Much has been said about antiseptic treatment in the case. It was practiced, I believe, to a very great extent. Its *practice* is grand, except the spray; I heartily agree with the German surgeon who said 'fort mit dem spray.' Could there be a better commentary on the *unproved theory* of antiseptic surgery than the President's case? Against its theory, or at least the effect of it on many minds, namely, that all sources

of contamination which produce septic poisoning come from without, I earnestly protest. I have too much respect for Mr. Lister to think that he believes what the extremists among his disciples teach.

"The influence of such teaching on the rising generation of physicians and surgeons is bad, in this, that it leads to narrow views and interferes with clear diagnosis. It leads outwardly too much, for contamination comes from within, I believe, more frequently than from without. Was not the decaying vertebra in the President's case enough to account for the septicæmia?

"To get all the rats out and then stop the hole with poison and stuffing is a good thing, but to poison and plug the hole and leave the rats in, is a very bad thing. They only undermine and make other holes. A narrow antiseptic looks around the room instead of at the patient, whereas he should look at both and give due weight to all septic possibilities."

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 12, 1881.

Deaths reported 2473 (no report from St. Louis or New Orleans): 921 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 704, consumption 379, diphtheria and croup 259, lung diseases 228, diarrhoeal diseases 113, typhoid fever 91, scarlet fever 67, small-pox 64, malarial fevers 46, whooping-cough 19, cerebro-spinal meningitis 17, erysipelas 14, puerperal fever nine, measles five. From *scarlet fever*, New York 25, Brooklyn 14, Philadelphia eight, Buffalo six, Chicago, Baltimore, and Pittsburgh three, Cincinnati,

District of Columbia, Providence, New Haven, and Lowell one. From *small-pox*, Chicago 25, Pittsburgh 22, Philadelphia 11, New York and Boston two, Baltimore and Cincinnati one. From *malarial fevers*, Brooklyn 13, New York nine, District of Columbia seven, Baltimore five, Chicago and Nashville four, Philadelphia and Buffalo two. From *whooping-cough*, New York seven, Brooklyn three, Philadelphia and Baltimore two, Chicago, Boston, Buffalo, Holyoke, and Haverhill one. From *cerebro-spinal meningitis*, Chicago three, New York, Philadelphia, Cincinnati, Pittsburgh, and Buffalo two, New Haven,

Nashville, Lowell, and Newburyport one. From *crisipelas*, Philadelphia three, New York and Buffalo two, Brooklyn, Chicago, Baltimore, Pittsburgh, Milwaukee, Cambridge, and Fall River one. From *puerperal fever*, District of Columbia two, New York, Philadelphia, Chicago, Boston, Cincinnati, Milwaukee, and Holyoke one. From *measles*, New York, Philadelphia, Buffalo, New Bedford, and Fitchburg one.

Ten cases of small-pox were reported in Brooklyn, two in Boston, three in Baltimore, 15 in Cincinnati, 53 in Pittsburgh, one in Buffalo, one in Springfield; diphtheria 25, typhoid fever 22, scarlet fever eight, in Boston; diphtheria 14, scarlet fever four, in Milwaukee.

In 42 cities and towns of Massachusetts, with a population of 1,092,053 (population of the State 1,783,086), the total death-rate for the week was 18.72 against 20.16 and 19.64 for the previous two weeks.

For the week ending October 22d in 149 German cities and towns, with an estimated population of 7,893,486, the death-rate was 22.9. Deaths reported 3746; under five 1608: pulmonary consumption 457, acute diseases of the respiratory organs 285, diphtheria and croup 173, scarlet fever 148, diarrheal diseases 115, whooping-cough 77, typhoid fever 54, puerperal fever 19, measles and röteln 11, small-pox (Aachen) two, typhus

fever (Posen) one. The death-rates ranged from 9.3 in Wiesbaden to 39 in Erfurt; Königsberg 24.7; Breslau 26.5; Munich 23.3; Dresden 20.5; Leipzig 20.9; Hamburg 22.3; Hannover 12.7; Bremen 16.4; Cologne 24.1; Frankfurt 14.5; Strasburg 20.7.

For the week ending October 29th in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 22. Deaths reported 3202: acute diseases of the respiratory organs (London) 376, scarlet fever 155, fever 82, measles 66, diarrhoea 54, whooping-cough 53, diphtheria 35, small-pox (London 21) 26. The death-rates ranged from 13.2 in Plymouth to 33.3 in Hull; Sheffield 16.8; Birmingham and Leeds 19.2; Bristol 20.7; Manchester 23.4; Liverpool 27.3. In Edinburgh 18.9, Glasgow 24; Dublin 23.

For the week ending October 22d in the 21 chief towns of Switzerland, population 479,934, there were 25 deaths from pulmonary consumption, acute diseases of respiratory organs and diarrheal diseases each 16, diphtheria and croup eight, typhoid fever six, whooping-cough three, puerperal fever and scarlet fever each one. The death-rates were, Geneva 20.5; Zurich 17.6; Basle 16.7; Berne 23.4; Solothurn 54.2.

The meteorological record for the week ending November 12th, in Boston, was as follows:—

Date.	Barometer.		Thermometer.		Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM NOVEMBER 12, 1881, TO NOVEMBER 18, 1881.

MCCLELLAN, ELY, major and surgeon. Having reported in person at these headquarters, will proceed to Fort McHenry, Md., and report to the commanding officer for duty. S. O. 204, Department of the East, November 17, 1881.

CARVALLO, C., captain and assistant surgeon. The leave of absence on surgeon's certificate of disability granted him in S. O. 108, October 24, 1881, Department of the Platte, is extended five months on surgeon's certificate of disability. S. O. 256, A. G. O., November 12, 1881.

LAUDERDALE, J. V., captain and assistant surgeon. On discontinuance of McPherson Barracks, Atlanta, Ga., assigned to duty at Jackson Barracks, La., to remain at McPherson Barracks until medical property, for which he is responsible, is disposed of. S. O. 124, Department of the South, November 10, 1881.

CRESSINGHAM, T. A., captain and assistant surgeon. Relieved from duty at Jackson Barracks, and assigned to duty at Mt. Vernon Barracks, Ala. S. O. 124, C. S., Department of the South.

BYRNE, C. B., captain and assistant surgeon. Temporarily at McPherson Barracks assigned to duty at Fort Barrancas, La. S. O. 124, C. S., Department of the South.

CANTER, J. C., first lieutenant and assistant surgeon. To accompany from Fort Adams, R. I., to the Military Division of the Pacific, the headquarters, band, Battery F, and detachment Light Battery K, First Artillery, ordered to start on 10th inst. S. O. 66, Military Division of the Atlantic, November 8, 1881.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next regular meeting will be held at the Medical Library Rooms, 19 Boylston Place, on the first Thursday of December, at 10 30 A. M. L. F. Warner, M. D., will read a paper on Periodical Headaches of Women. Profession invited.

HENRY M. FIELD, M. D., Secretary.

BOOKS AND PAMPHLETS RECEIVED. — A Manual of Practical Normal Histology. By T. Mitchell Prudden, M. D., Director of the Physiological and Pathological Laboratory of the Alumni Association of the College of Physicians and Surgeons, New York. New York: G. P. Putnam's Sons. 1881.

Transactions of the American Otological Society. Fourteenth Annual Meeting, Newport, R. I., July 26, 1881. Vol. II. Part 5. Boston: A. Williams & Co. 1881.

The Physician's Hand-Book for 1882. By William Elmer, M. D., and Albert D. Elmer, M. D. New York: W. A. Townsend, 1882.

The Anatomist, being a Complete Description of the Anatomy of the Human Body, intended for the Use of Students preparing for Examination at the Royal Colleges of Surgeons and other Medical Bodies. Second Edition, improved and enlarged by the addition of one hundred and seventy-one Wood Engravings. By M. H. Hilses, formerly Lecturer on Anatomy and Physiology at the Westminster Hospital School of Medicine, etc. New York: G. P. Putnam's Sons. 1881.

Observations on the Origin, Character, and Treatment of Onomania. By T. L. Wright, M. D. (Reprint.)

Atresia of the Vagina and Uterus. By A. F. Erich, M. D. (Reprint.)

How to Use the Bromides. By George M. Beard, M. D. (Reprint.)

Lectures.

CLINICAL LECTURES ON THE DISTINCTIONS BETWEEN THE INFLAMMATORY DISEASES OF JOINTS.

DELIVERED AT BELLEVUE HOSPITAL.

BY W. H. THOMSON, M. D.,

Professor Materia Medica and Therapeutics, University of New York.

I.

GENTLEMEN,—Inflammatory diseases of joints are necessarily much alike in their symptoms, owing to the nature of the parts affected. The functions of joints are so simple and mechanical that they do not admit of a great variety of signs in their derangements, no matter how these may differ in kind or origin. A swollen and painful knee, for example, may look to you and feel to the patient very much the same, whether it was due to a fall on the ice, or to an attack of gout, or to rheumatism, or to pyæmia, or to scarlet fever, or to gonorrhœa. These are each very different morbid conditions, so distinct, indeed, that there can be no crossing between them. Thus there is no such hybrid as a rheumatic gout any more than a fall on the ice can cause an attack of clap, but so similar are the mere symptomatic characters of all arthritic inflammations that they are readily confounded, and are likely to occasion more errors in diagnosis than any other common affections of the body. The most serious inconvenience from this fact, however, is that it leads to worse confusion in treatment, because it is only after correct diagnosis that we can choose the most proper procedure to adopt in each case, and hence it has appeared to me as a profitable subject for us to learn how we can discriminate between the various inflammatory affections to which joints are liable.

We will begin, therefore, with the contrasts between those of them which you will oftenest meet in practice, namely, rheumatism and gout. When called to a case with the first attack of either of these maladies, the differential diagnosis is often easily made, but not so after the patient has had so many returns of his trouble that most of the joints of both upper and lower extremities have suffered, perhaps repeatedly or for prolonged periods. Your ultimate decision, however, need never be very uncertain, to show which we will proceed at once to point out in these patients which we have before us now those features which will serve to distinguish the one from the other, no matter how much they may come in time to resemble each other.

The first is a young man, twenty-six years of age, by occupation a hotel porter, who gives the following history: In his work he was frequently exposed to cold draughts, and often had to step out in his shirt sleeves on cold winter days while in a state of perspiration. He enjoyed excellent health, however, until nine weeks ago, when he says that he caught cold while at work, and without any preliminary period of malaise he began to suffer in his left foot, which became very painful and swollen about the instep. In three or four days he was unable to wear a shoe on it, and shortly afterwards he was attacked with pains all over his body, affecting successively the knees, shoulders, elbows, and wrists, accompanied with high fever and much perspiration, when he was removed to this hospital, where he has been slowly improving for six weeks with the usual course of varying returns of in-

flamations in different joints. Our second patient is also a young man with a similar history, this also being his first attack, but definitely dating from a prolonged wetting while at work. The third patient, however, presents wholly different features. He is not only an elderly man, but a veteran in "rheumatism," as he says. His first experience of it was nineteen years ago. It began in the left foot and it remained there alone during that attack. His second attack was about a year afterwards, and in the same foot, but this time especially in the great toe. His next attack was in the ankle of the same foot, then, about two years afterwards, in the right foot; shortly afterwards in the right knee, then the left knee, and then, some years afterwards, his fingers, wrists, and elbows were successively affected, until now his relapses are about equally divided between the two extremities.

Here, therefore, we have polyarthritic inflammations in all three of these patients, and yet, from the facts already elicited, without entering upon many other contrasts between them, we can hardly be mistaken in diagnosing the first two as rheumatism and the third as gout, for these reasons:—

The ages of the first two almost as surely exclude gout as they afford a presumption of rheumatism. A first attack of articular rheumatism after forty is rare, a first attack after thirty is also uncommon. Acute articular rheumatism is a disease of early youth and early adult life. It may occur in children, but its first invasion is oftenest between fifteen and twenty-one years of age. After it has once made its ill-omened visit, however, it is almost sure to recur again and again up to middle life or even a little longer, but the liability to it progressively diminishes with each year after thirty, even with those who have suffered severely from it in early life. Chronic muscular rheumatism, on the other hand, is a very different disease. In contrast to articular rheumatism it is the torment of post-middle and advanced life, and often occurs in persons who never had acute articular rheumatism at all, as we will show further on.

Gout, on the contrary, is almost exclusively a disease of adult or advancing age. The liability to it increases with every year after thirty up to fifty. With this man it commenced when he was about forty years old, and began in a way so characteristic that it should be noted as a distinguishing mark from rheumatism. It began in the left foot. But so also did the rheumatism in the first young man. There was this important difference, however, the rheumatic foot did not remain the only suffering part in the first attack, instead of that in a few days it spread to the whole body. Gout almost never does this. In the great majority of cases its first attack is local and solitary. Not only so, but it continues for a long time, for years in most cases, to return only to the lower extremities. When once, however, it gets above the knees it becomes quite indiscriminate in its selections, as our present patient illustrates.

We now proceed to another contrast to be found in the pulse. Very often it is practicable to be tolerably sure which of the two we have to deal with from a few qualities of the pulse alone. To demonstrate this fact, however, a few words about pulse examination are needful in explanation.

The commonest elements in any given pulse are six, namely, three cardiac and three vascular. Those elements in the pulse which depend exclusively upon the

action and state of the heart, are first, its frequency, second, its strength, and third, its rhythm, while those which depend upon the state of the arteries are first, its size, that is, whether it be large or small, second, its length, that is, whether it pass rapidly or slowly under the finger, and third, its tension, that is, whether it be incompressible or hard, or whether it be compressible or soft. Now it is in these latter two respects that a striking difference is to be detected between rheumatism and gout. The pulse of rheumatism is at all times remarkably short and compressible, much like the pulse of phthisis, and of the fevers and inflammations generally, except scarlet fever, peritonitis, and the earliest stage of pleurisy. The pulse of gout, on the other hand, is as characteristically long and incompressible; resembling closely in these respects the pulse of Bright's disease and of scarlet fever.

What is the cause of this difference in the pulse between rheumatism and gout? An incompressible pulse always means that the arteries are *overfull*, owing to obstruction in the arterioles and in the capillaries. This may be due to nervous irritation leading to narrowing spasm of these vessels, as in peritonitis and the first stage of pleurisy from shock, or to a permanent lessening of their calibre from chronic endarteritis, as in Bright's disease, or to both causes combined. Let obstruction to the exit of the blood from the arteries, therefore, obtain from either of these conditions, and the vessel becomes more and more like a hose filled with water with the stop cock shut off. You have to use greater pressure to obliterate the radial under your finger, and the pulse, therefore, feels hard, or, as it is technically termed, incompressible. Moreover, the vibration of the onward moving blood in such a vessel necessarily becomes more prolonged in proportion to the overfilling of the vessel, and hence gives you the other character, namely, the long pulse. On the contrary let the arterioles and the capillaries be widely relaxed or open, and the arteries must necessarily be easily and quickly emptied, and hence, also, the pulse be easily compressed on the one hand, while the pulse wave on the other will be correspondingly short, because it flows so quickly under your finger.

The indications, therefore, which these contrasts show as to the different nature of these two diseases are plain. In gout we have a well-known, insoluble poison, uric acid, circulating in the blood, which acts as an irritant to the walls of the arterioles and capillaries, and thus leads to their contraction. In rheumatism, on the other hand, if we have any blood-poison at all, it is evidently a perfectly soluble one, like the poison from decomposed pus in hectic from any cause, as phthisis, from abscess, etc., and which always acts as an arterial paralyser instead of as an irritant, and hence dilates the arterioles instead of contracting them, thus producing the characteristic compressible short pulse. What an important bearing this fact has, not only as indicating the essentially different nature of these two diseases, but also what different consequences to the bodily textures result from this difference, we will soon discuss. You need only examine the radials of these patients before you can appreciate readily this distinction. In the case of these young men you cannot feel their arteries either at or above their wrists, you can only tell that they have these blood-vessels by feeling the throb of the pulse. In the gouty patient, on the other hand, you can feel his radial half way up his arm, as if it were a hard cord lying among the tendons, and it rolls under your finger

almost like a wire. In the rheumatics, also, you can readily obliterate the pulse by slight pressure with one finger; in the gouty patient, on the other hand, you may place three of your fingers on the vessel and find that the pulse remains distinct under all three fingers, even though you use much more pressure with them than you did with one finger in the others. Now it is true that the arteries naturally harden with age, and yet it is not usual to find them so rigid and incompressible as in this case unless caused by toxic endarteritis, either from deficient action of the kidneys or from the prolonged irritation of the gouty poison.

We now come to the anatomical differences characteristic of the operation of these two affections. Rheumatism is remarkable for the insignificant traces which it leaves behind it in the textures which it attacks. When you see a knee, for instance, acutely inflamed by rheumatism, and note the great redness, heat, and swelling, and find also that it is exquisitely tender, you very naturally conclude that such a high inflammation must be very injurious to the joints. Indeed, if symptoms of the same degree of severity were caused in a joint by anything else than rheumatism, by a railway accident, for example, you would have much cause to fear that the joint would be irretrievably ruined. But should your rheumatic patient die in only forty-eight hours thereafter, it is very likely that you would find strangely few indications that his knee had been seriously inflamed at all. Great cry and little wool, as the man remarked when he sheared the sow, no pus, no ulceration, and perhaps not even effusion of any kind. Moreover, without death, you will often find that a seemingly violent inflammation of some joint, present one day, has apparently been all transferred to a distant joint the next day, and then to another the next.

It is unfortunately true, however, that some very serious anatomical changes accompany certain rheumatic inflammations, namely, when the heart or its appendages are involved, but there is a special reason for this, quite independent of the natural action of the rheumatic process itself. Thus if you should seize a badly inflamed rheumatic knee and move it briskly one hundred times a minute it is hard to say what would become of the joint. The patient, at least, takes good care not to move it at all; but he cannot keep his heart quiet, no matter how badly it is inflamed, and it is probably due to this fact alone that rheumatic carditis is so apt to be followed by textural changes. This inference is also borne out by the similar, though much rarer, changes caused in rheumatic pleurisy, for here we have also an unresting texture, though proportionately less liable than the heart to structural lesions of rheumatic origin as its movements are the fewer.

In complete contrast to the insignificant and transient damage done by rheumatism, gout never fails to leave its mark wherever it has made a visit. A man will show a white spot in the articular cartilage of the great toe made by a solitary attack of the disease in him twenty years before, and each time it returns it adds to its previous mementoes. Sooner or later it distorts one articulation after another with its deposits and its thickenings, for which there is no cure. Not so with true rheumatism. The prognosis for a rheumatic joint is good no matter how long the disease has lasted or how old the patient may be, as we will show when we come to the subject of treatment.

A CASE OF CYSTICERCUS IN THE SUBSTANCE OF THE SPINAL CORD.

BY GEORGE L. WALTON, M. D.

THIS parasite, though by no means of rare occurrence in the brain,¹ is not often found in the spinal canal, and when found there lies generally, like the echinococcus, between the membranes. Rokitsky states² that it may also occur in the substance of the cord, though I find no record of cases in Heller, Küchenmeister, or Leuckart, the latest authorities on parasites. Devaine I have not been able to consult.

Perhaps the rarity with which the cysticercus is found in the cord may be largely due to the rarity with which the cord is examined.

The case under the care of Prof. E. Wagner, in the Leipzig Hospital, was one of *tubercles dorsalis*, so diagnosed before death. The cysticercus I found while making preparations of the cord, kindly given me to examine by Dr. Strümpel, his first assistant.

Unfortunately the clinical history of the case is very meagre, the patient having been brought to the hospital in the last stages of the disease, and unable to answer questions. The following is the history as found in the hospital records:—

P. F., a butcher's widow, fifty-six years old, was brought to the hospital in a very dirty and neglected condition. Makes almost no reply to questions. Says she has been unwell only sixteen weeks, and that during that time her legs have been paralyzed. On being closely questioned as to pain in the limbs she gives no answer. Patient is a marasmic old woman, covered with dirt. Over the sacrum is a deep and sloughing decubitus the size of the hand. On the legs are found in places inflamed spots on the skin, in places deep ulceration; the legs lay stretched in bed quite lax; remarkably loose condition of the knee and ankle-joints (*schlotterbeweglichkeit*); active motion in legs not entirely absent, slight movements are carried out; pricks of a pin up to the head in the flesh call out absolutely no reaction, the same loss of sensation being found in face, arms, and legs; tendon reflex in legs wanting; on the vertebrae a senile hyphoseoliosis not at all sensitive to pressure; no protrusion of separate spinous processes; pupils alike, rather under middle size, and do not react to light; has quite high fever; seems often to feel cold, but no chills; mutters continually in a low tone; eyes always half open; swallows hardly at all; arms not paralyzed, are held continually to the side in a state of contraction; urine and faeces passed almost hourly in bed. An exact examination is absolutely impossible.

Fourth day. Delirium has ceased; patient looks better; answers only the simplest questions, and is still very stupid; the deepest insertion of the pin into legs, arms, and face calls out no reaction.

Twenty-first day. General condition has become gradually worse; examination of the nervous system absolutely impossible; legs not completely paralyzed; movements of foot quite good, in knee less so; pupils rather narrow, but do not react to light.

Twenty-second day. Died without further symptoms.

¹ Birsch-Hirschfeld quotes Virchow as saying that two per cent. of brains examined by him contained cysticercus.

² Lehrbuch der Pathologischen Anatomie, Band II., 1856.

The clinical chart shows a very irregular fever curve, ranging from 37° to 41° C., with pulse and respiration proportionally high.

The autopsy, made by Dr. Huber, showed slight oedema and emphysema of lungs, calcification of arteries, indurated kidneys, slight fatty degeneration of heart muscles, slight uterine infarction, slight hæmorrhagic endometritis, and cysticercus cerebri.

The description of the brain was as follows: membranes on base and convexity soft, thickened, and exhibiting a milky opacity. In four places on the surface, and in the anterior part of the right corpus striatum were found round cysts of about bean-size, with sharply-bounded and, in parts, thickened walls; contents clear fluid; each cyst contained a small, round body on its inner surface (*cysticercus*). Brain substance poor in blood, consistent. The seats of the cysts at the surface of the brain were the middle of Broca's convolution on the right, the occipital convolutions on the left, the middle temporal convolution on the right.

The cord showed typical appearances of *tubercles*. Pia mater rather adherent, especially over the posterior columns. Posterior columns soft, gray, and degenerated. Axis cylinders atrophied, and nerve fibres replaced in great measure by solid connective tissue, in the columns of Goll almost completely so. Corpora amylacea abundant. The gray substance was involved, the nerve fibres in the median and posterior portions being indistinct, the sections presenting in this region a hazy, transparent look, quite unlike normal gray substance. The anterior horns were normal. No atrophy of the motor ganglia except at the location of the cyst. These abnormal appearances extended the whole length of the cord, and were equally marked on both sides. The cyst was situated in the upper cervical region, at the level of the third to the fourth spinal nerves. There was nothing on the outside of the cord to indicate its presence excepting that the left side was slightly larger than the right. The cyst was oval, about six mm. by five mm. at its greatest diameters, and occupied the situation of the gray matter on the left side. At the point of greatest breadth of the cyst only a narrow strip of gray matter remained, with atrophied ganglion cells, as shown in the cut below.

This cut represents a section through the middle of the cyst, and shows two cavities separated by a septum of connective tissue. To explain this septum I need only state that the animal with its sack was bent upon itself. A section through the head with its four suckers may still be seen on one side of the septum. A section taken higher up (not shown) displays the characteristic crown of hooklets, the largest measuring 0.12 m. A capsule of firm connective tissue separated the cyst from the surrounding nerve tissue, which was of normal consistency, and microscopically unaltered excepting that the motor ganglia were atrophied.

The case admits of little or no discussion physiolog-

ically or pathologically as far as the cyst in the cord is concerned, as there is no record of symptoms referable to it.

The picture was one of the last stage of tabes. Extreme emaciation, decubitus, paralysis of bladder and rectum, loss of power and sensation, absence of tendon reflexes, pupils not reacting to light. To what extent the cysticerci in the brain and cord contributed to or modified the symptoms is not easy to determine from the data before us.

There is no note of any unilateral disturbance or of any local atrophy. Total absence of symptoms referable to the cyst in the cord would not be surprising, for in the disease called syringomyelitis quite large cysts are found in the cord, which during life have caused no symptoms.

To show the comparative frequency with which the cysticercus has been found in other parts of the body I quote from Küchenmeister and Zürn.¹

In three thousand reported by Delore and Bonhomme, two thousand were found in the cellular and connective tissue under the skin, nine hundred in the muscles, eighty-four in brain, twenty-two in the meninges, sixteen in the lungs, "several" in the carotids, four in cerebellum, and one in each heart, pancreas, and medulla. None in liver, spleen, or kidneys. In eighty-seven cases by Dressel, seventy-two were found in the brain, thirteen in the voluntary muscles, six in the heart, three in the lungs, and three in the subcutaneous cellular tissue. That no mention of the spinal cord is made in these statistics may be due to the fact that it was not examined.

The eye is not an infrequent seat for the cysticercus, its discovery here being facilitated by the use of the ophthalmoscope. Von Gräfe determined in this way the time required for the attainment of its full size, which he states to be about two and one half months.

In the brain the cysticercus is much oftener found than the echinococcus, but in the spinal canal the case is reversed, though all echinococci reported have been found in the membranes, and none in the substance of the cord. Devaine² has collected reports of thirteen cases of echinococcus in the membranes.

Birch-Hirschfeld says in this connection, "Im Betreff der im Rückenmark beobachteten Parasiten, ist das sehr seltene Vorkommen des Cysticercus Cellulosæ zu erwähnen (Devaine, Rokitsky) Echinococcus wurde zwar im Sack der Dura Spinalis gefunden, nicht aber bis jetzt in der Substanz des Rückenmarks selbst."

The cysticercus is found most often between the ages of twenty and sixty, and more often in men than in women (Küchenmeister).

The geographical distribution of the cysticercus agrees with that of the *trinia solium*, and since the spread of the latter among men is due to the eating of swine flesh infected with cysticercus, it follows that those people who refrain from pork are free from both *trinia solium* and *cysticercus cellulosæ*.³

An individual with a tapeworm may infect himself with cysticercus, the ova penetrating his intestine, and being carried in the circulation to the seat in which it later becomes encysted.

An interesting fact in this connection is that the patient was the widow of a butcher, a class among whom the cysticercus is quite common.

CASE OF RHEUMATIC CHOREA. RECOVERY IN FIFTEEN DAYS UNDER SALICYLIC TREATMENT.⁴

BY S. L. ABBOT, M. D.

THE patient, M. A. N., housemaid, twenty-four years old, entered the Massachusetts General Hospital June 7, 1881, suffering from severe chorea. She had been an inmate of the hospital during the early spring, while suffering from acute rheumatism, and had been discharged well five weeks before. She had had slight pain in her left hand after leaving the hospital, and this had increased somewhat during the previous week. She thought that for two or three years past she had been gradually losing control over movements of hands and feet. During the three weeks before her present admission to the hospital symptoms of chorea had appeared, and were now very severe. The face was constantly twitching, the hands were in constant motion; there was great difficulty in articulation and deglutition, and the patient incessantly changed her position in bed; her appetite was good, but she was unable to feed herself; functions of bowels, bladder, and uterus normal; examination showed no abnormal heart sounds; pulse 78, regular, of good strength.

The patient was put on full house diet, and liquor. Potass. arsenitis, three minims, was prescribed, to be taken after each meal.

On the 9th, on account of the restlessness of the previous night, extract of *cannabis indica*, one half grain, was ordered to be given before each meal. This was followed by good nights until the 12th, the dose of arsenic having been increased to five minims *ter in die*. On this day complaint was made of pain in the right popliteal region, and the choreic movements were not diminished. The arsenic and Indian hemp were accordingly omitted, and salicylate of soda was prescribed, to be taken in ten-grain doses every two hours.

On the next day the pain was less, but the choreic movements continued.

June 14th. Patient reported to have slept well all night and most of yesterday; movements less marked; some tinnitus last evening; pain relieved. It was determined to continue the remedy, however, to decide whether it had any positive influence on the chorea, but the dose was reduced to six grains every two hours.

June 15th. Movements very much less.

June 16th, the fourth day of the salicylate treatment. Patient is able to feed herself. The dose of salicylate was increased to eight grains, and on the 18th to ten grains, the patient steadily improving; on the 22d, on account of discomfort in the head, apparently caused by the medicine, its use was discontinued.

On the 25th the patient reported some increase of stiffness with soreness of the right hand, and the choreic movements had perceptibly increased. The salicylate of soda was accordingly resumed in the dose of ten grains every two hours.

June 26th. Patient comfortable; scarcely any chorea; salicylate to be given every three hours; it was discontinued on the following night, however, on account of pain in the stomach; salicin was now substituted for it, ten grains to be taken every three hours.

June 27th. Scarcely a trace of chorea; articulation

⁴ Read before the medical section of the Suffolk District Medical Society, October 22, 1881.

more distinct, and patient generally better than since entrance.

On the 30th the patient wrote her name in a perfectly legible, almost a handsome hand, as may be seen in the Hospital Record Book.¹ At the time of entrance she could hardly hold a pen in her hand. As the treatment by salicylate of soda was begun on the 12th, and was omitted on one occasion for three days, during which the chorea increased, it will be seen that this fortunate result followed its employment for only fifteen days. The temperature throughout was about normal, once only rising to 99.6° F., and once falling to 97° F. after the chorea had ceased.

The patient was discharged well on the 19th of July, having had no choreic movements for two weeks previous, during which interval the doses of salicin had been gradually diminished.

A case of rheumatic chorea reported by Dr. B. F. Gary has been recently published in the Transactions of the South Carolina Medical Association, and copied into the *Medical Record* of October 8, 1881. In that case chorea was developed during convalescence from acute rheumatism, and was most vigorously treated by a great variety of remedies, except those containing salicylic acid, without benefit. The symptoms were increasing and very grave in character. At last the tincture of veratrum viride was given in a ten-drop dose, to be repeated in two hours, with an increase of two drops to every dose until nausea or a great reduction of the pulse should be produced. Emesis followed the dose of eighteen drops, and the pulse fell to 50, with great general prostration. This was relieved by stimulants, and there was a diminution of the choreic movements. The remedy was resumed in smaller doses, graduated to the movements. Daily improvement followed, and recovery was complete at the end of two months.

So far as the experience of the writer is concerned, rheumatic chorea is a very rare disease. Among a very large number of cases of chorea seen by him in former years in the out-patient department of the Massachusetts General Hospital he got a history of rheumatism in scarcely a single instance; he has seen but two cases of rheumatic chorea since, one of which is the present case. It has been claimed by some writers, especially by M. Sée, that chorea is essentially a rheumatic disease, but he believes that the general experience of the medical profession is quite at variance with this opinion. The success in the present instance of the remedies now generally used for acute rheumatism suggests the expediency of trying them in cases of pure chorea without rheumatic history. As it is well known they are efficient in some forms of pure neuralgia without rheumatic history, it may possibly prove that the affection of the motor nerves known as chorea may yield to the same treatment, thus showing in both a probable relation to rheumatism not so apparent before. He has been very anxious to try the experiment in an ordinary case of chorea, but as yet no opportunity has offered. It is hoped that some member of the profession may be led to try it, and report the result.

—Walsh's Physicians' Handy Ledger and his combined Call-Book and Tablets for 1882, have made their appearance and evidently meet with favor among members of the profession.

THE TREATMENT OF DIPHTHERIA.²

BY JAMES B. AYER, M. D.

SINCE 1857, when Watson, in his Principles and Practice of Medicine, stated that he had seen only two or three cases of diphtheria, and the disease was not even mentioned in the mortality reports of this Commonwealth, diphtheria has increased with alarming rapidity, and is now the third most frequent cause of death in Massachusetts.

The treatment of the disease has been thoroughly discussed during the past few years; it was brought prominently before the International Medical Congress and the American Medical Association at their recent meetings.

My belief that the interest in the subject is undiminished, and that the views of the profession are not united, are my apologies for again introducing it.

While nothing can be more unreliable than statistics of recovery from diphtheria, on account of the difference in severity of epidemics, yet from a fair experience with the disease I feel convinced that the *early and thorough use* of remedies already known yields a satisfactory proportion of recoveries, saving many of the worst cases.

It is now generally admitted that diphtheria is both a local and constitutional disease.

In some cases the constitutional symptoms are noticed after the appearance of diphtheritic deposit in the fauces. In others the constitutional symptoms occur at the same time with or precede the local symptoms.

In *all* cases the treatment from the outset must be local and constitutional.

LOCAL TREATMENT.

According to the best investigators, and asserted by Klebs at the International Medical Congress last August, the blood can be rendered septic by absorption of the spherical collections of micrococci which exist in diphtheritic membrane.

Those who have seen the irregularly ragged patches of diphtheritic deposit closely attached to the underlying congested tissue can easily believe that infection occurs in this manner.

Hueter, Tommasi, and Oertel in their experiments upon animals found that they died, on the second day after inoculation with diphtheritic virus, of general blood poisoning. In some cases a diphtheritic membrane appeared on the edges of the wound; in other cases the symptoms were simply those of septicæmia produced by any virulent decomposing animal matter.

I can speak from experience regarding the violence of septic symptoms from diphtheritic inoculation.

Last January, while examining a diphtheritic case which proved to be mild, in a three-year old girl, previously in perfect health, I unguardedly allowed myself to be bitten at the last joint of the index finger of the right hand. The slight abrasion seemed unimportant until, a few days later, the lymphatics became swollen and tender and the axillary glands enlarged and hardened. In a month the axillary glandular region had formed a large mass and began to suppurate, and was lanced by Dr. James Ayer. There was only a moderate amount of discharge until three weeks later, when it became very copious, continuing so a fortnight, and then gradually lessened from week to

² Read before the Medical Section of the Suffolk District Medical Society, October 22, 1881.

week. The finger had a boggy, oedematous appearance, with deep purulent infiltration. Dr. J. C. Warren made a slight incision at the seat of the original wound, to allow free exit of deep matter. All the physicians who saw me agreed that I was suffering from septicæmia caused by the inoculation of decomposing diphtheritic matter. The finger later became eczematous; for months resisted, and then very slowly yielded to treatment.

The constitutional symptoms were characterized by great debility, occasional fever, and profuse sweating.

I faithfully took pints of iron, quinine, and strychnia preparations and stimulants, — principally in the form of egg-noggs, — also most nourishing diet; but over six months elapsed before the local symptoms had subsided and the general health was restored.

Believing in the importance of local treatment to destroy, if possible, the disease before it can be absorbed, I would mention the formula so much used, and which has done excellent service in the practice of Dr. James Ayer and myself: —

℞ Liq. ferri subsulph. 5ij
Acid. carbolic. (fort.) Mijj.
Glycerin ad 5i. M.

"Use every four hours, at first diluting with an equal amount of water, and gradually increasing until full strength is used."

I prefer a camel's-hair brush with short hairs, and try to pass the brush underneath the diphtheritic deposit and to force out all that I can.

I know that Tobold says "such treatment should be absolutely repudiated," and that MacKenzie advocates a varnish of tain and ether instead of a styptic thoroughly applied, but I believe with the best of our American authorities that vigorous means are necessary from the beginning in such a desperate disease as diphtheria. I do not remember to have seen the disease carried to healthy membrane by the use of the brush, but on the contrary know that this treatment hastens the disappearance of the membrane from the throat in the great majority of cases.

Where the nares are affected, the following, recommended by Flint for disinfecting the nostrils, can be advised: —

℞ Acid. carbolic. gr. xxiv.
Glycerin 5ij.
Aque 5i. M.

S. "Repeat injection every third or fourth hour."

Steam inhalations are of great importance in the treatment of diphtheria. The following mixture, equal parts of two per cent. solution of carbolic acid, saturated solution of chlorate of potash, and liq. calcis should be employed five to ten minutes out of each hour, day and night, when the case is desperate.

As a substitute a weak solution of alcohol can be frequently used with the steam. I have seen decided benefit from the use of alcohol in this manner, the membranes shrivelling quite rapidly. Many of the best observers have mentioned the efficacy of alcohol in destroying the germs of diphtheria.

The patient's head should be surrounded by warm, moist air in the interval between the inhalations. This can be easily carried out by keeping the inhaler in use near the head of the bed without feeding the cup with medicated fluid.

To the objections raised against this thorough and constant treatment Jacobi (?) well replies: "There is no objection to this activity in treatment on the ground

of keeping the patient disturbed the whole time, for the local applications and steaming keep the throat clean and get rid of the septic matter which forms before it is taken into the system."

This treatment cannot be carried out without the assistance of an experienced nurse who will follow implicitly the physician's directions. In a few hours the child will cease to struggle against the local applications and inhalations.

In regard to the use of carbolic acid it will be well to watch the urine, though I have never seen symptoms in any diphtheritic case of carbolic poisoning.

Gargles need not be used when steam inhalations are employed.

Liniments are indicated when there is glandular enlargement, flaxseed poultices or hot-water compresses when the swelling is prominent and painful.

As alternating hot and cold applications are soothing to an inflamed throat, small bits of ice and ice-cream should be occasionally given.

General treatment is not less important than local. With my experience of debility attending septic poisoning I am a strong advocate of iron and quinine from the outset of the disease. To a child six years old I would give ten to fifteen drops of tincture of chloride of iron and a half grain of quinine every four hours. When the pulse is frequent and weak the dose should be much increased.

The treatment should be stimulating, and depleting measures should not be thought of. There is danger of not giving spirits in sufficient amount when the heart is weakened. Charles West gave in one day to a child four years old four ounces of brandy and four ounces of port wine with good results. To a child of that age I give a teaspoonful of brandy every two, three, or four hours. Of course, strong liquid nourishment should be given at frequent intervals.

There are other good remedies which have not been mentioned, I have only referred to those which seemed to me the most important. Pilocarpin and other debilitating remedies should not be employed.

The physician should arrest diarrhoea or any debilitating complication. The patient should be kept in bed in a well-aired room, in an even temperature, and the rules regarding infection insisted upon by boards of health rigidly carried out.

In most severe cases of diphtheria the physician is constantly watching indications for tracheotomy. Most authors agree that the operation is not advisable unless there is danger of suffocation through stenosis of the larynx.

In the following case life could probably have been saved if surgical assistance had been at hand: —

Edwin C., six years of age, November 8, 1875, after a hearty breakfast, went to school, but remained at home in the afternoon, complaining of sore throat. On the 9th there was high fever and a large amount of foul exudation in the throat. On the 10th fever had disappeared and there was less odor to the diphtheritic membrane. At 11.30 A. M. of the following day the respiration was harsh and more labored, but there was no dyspnoea nor lividity. There was no appearance of imminent danger at this visit, but I left word to be called if there should be any change for the worse. There was no change during the three hours following, the patient remaining comfortable, but at 2.15 P. M. he suddenly became blue in the face, and gasped for breath. He caught his breath a few times,

and showed no further sign of life. I believed that an autopsy would have shown that the larynx was obstructed by false membrane.

In cases of diphtheritic laryngo-tracheitis (formerly called sporadic membranous croup) we have the most difficulty in deciding as to the advisability of operating, since paroxysms of dyspnoea are present and sometimes lividity. In four cases (one of which recovered) the operation seemed inadvisable on the ground that the disease was not confined to the larynx. The following is the history of one of the cases:—

Leroy T., two years old, entered the nursery of the Home for Little Wanderers March 2, 1880, suffering with a slight cold. Nothing of special importance was noticed until March 10th, when he became hoarse. On the 11th a small white patch was visible in the fauces, and the respiration became rapid; he suffered somewhat from dyspnoea, but not in croup-like exacerbations; temperature 101.8° F.; he took nourishment well. On the following day there was only a small patch visible in the throat, but the general symptoms were aggravated; respiration 50 to 75, and the little patient appeared much weaker. At 12.30 p. m. of the same day Dr. J. C. Warren saw him in consultation. We decided that the dyspnoea was not caused alone by exudation in the larynx, and would be little benefited by an operation. At 4.30 p. m. the child died in a suffocative paroxysm, within sixty hours of the appearance of the first important symptom of the disease.

At the autopsy I found a delicate membrane lining the larynx (not apparently attached to the cords) and extending half way down the trachea. There was a semi-purulent exudation in the lower part of the trachea and in the large and small bronchial tubes. Near the bifurcation there was found a small patch of delicate membrane.

When diphtheria occurs as a sequela or in connection with other diseases, notably scarlatina, measles, and typhoid fever, it should receive thorough treatment.

After the throat and nasal passages the pudenda and vaginal mucous membrane are the most frequent seats of diphtheritic deposit, although very rare in these locations.

The following case in illustration shows the success of simple treatment:—

Miss H., nine years of age, October 11, 1880, had white patches upon the tonsils, but without severe constitutional symptoms. During the following thirty-six hours the patches rapidly extended in spite of treatment; distinct diphtheritic membrane, one cm. by one and one fourth cm., came from the nasal passages. On the 13th the diphtheritic trouble in the fauces and nares seemed well under control, and the constitutional symptoms were not severe. She complained, however, of pain when she passed water. On the following day, as dysuria continued, an examination was made. The vulva was found oedematous and superficially gangrenous; there was an ichorous discharge.

Cloths wet with carbolic acid, one to eighty, were applied. Several times daily the labia were separated, and the whole gangrenous region was thoroughly bathed with the same lotion.

On the 15th, the patient having failed to pass water for thirty hours, I attempted to pass a catheter, but after exposing the patient with the advantage of noon-day sunlight, I had great difficulty in finding the meatus. During the examination the clitoris came away in my hand. There was no further sloughing of the parts,

oedema and gangrene rapidly disappeared, and dysuria disappeared. In a few days convalescent, she gradually regained strength without further complications.

In regard to subsequent paralysis. Most of the cases which I have seen have been mild, yielding rapidly to tonic treatment and to kneading. The most obstinate symptoms were shown in a case of Dr. James Ayer's, a lady fifty-five years of age, in whom, four weeks after recovery from a severe attack of diphtheria, partial paralysis of the extremities appeared, more marked upon the right side. She was able to walk about, but in a very clumsy manner. She could not cut her food nor raise a cup to her lips, but could feed herself slowly and awkwardly by using a spoon.

In addition to iron, quinine, strychnia, and kneading, faradization was thoroughly tried. For six weeks there was little benefit under treatment, then improvement became rapid, and in two months she had regained the use of her limbs.

RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

BY WILLIAM F. WHITNEY, M. D.

THE ETIOLOGY OF TUMORS.

LEOPOLD¹ has undertaken a series of experiments with a view of supporting the theory advanced by Cohnheim, that the true course of a tumor, occurring in later life, is to be sought in a fault or irregularity of the embryonic layers; and that a tumor is therefore to be defined as "an atypical new formation of tissue of embryonic foundation."

His experiments consisted in transplanting portions of fetal animals upon and into adult animals. A method which had already succeeded in the hands of Zohn² and who interprets the positive results which have been previously obtained after using the deeper layers of the epithelium and periosteum of the adult by supposing that these cells more nearly approach a fetal condition.

Leopold first brought bits of cartilage of rabbit embryos, which measured from two and one half to six centimetres in length, into the anterior chamber of the eye, and found that they grew there to eighty and even three hundred times the size of the original implanted piece. In one case, where bits of cartilage were used in the peritoneum, they not only increased in size but even went on to the production of true bone. On the other hand, when bits of a larger fetus were used or from an adult animal, the piece was simply absorbed in the course of time.

These facts he considers as giving a strong basis to the theory of Cohnheim, and the part which traumatic irritation plays in the production of tumors is to be considered merely as secondary, and would fail, as a cause, if it did not have this atypical arrangement of fetal tissue to work upon.

THE ORIGIN OF RANULA, THE CYSTS OF BARTHOLINI'S GLANDS, AND THE CILIATED CYSTS OF THE LIVER

is the subject of an exhaustive article by Von Recklinghausen.³ The fortunate discovery of a ranula, which had never been operated upon, in the body of a

¹ Virchow's Archiv, vol. lxxxv. p. 283.

² Congres medical international de Genève. 1878.

³ Virchow's Archiv, vol. lxxxiv. p. 483.

woman, who died from tuberculosis, led to a careful investigation of it with the hope of settling the question as to its true origin. On the one side, it is contended that the ranula is caused by a dilatation of the duct of the submaxillary gland (Wharton's duct); on the other, that it is essentially a mucous retention cyst and has nothing to do with the saliva. The subject is further confused by the fact that all sublingual cysts have received the name of ranula.

The cyst in Von Recklinghausen's case occupied the seat of the classical ranula, beneath the tongue and slightly to one side of the median line, close to the frænum. The cyst contained a slightly yellow, almost transparent, slimy fluid, which was found by Hoppe-Seyler to contain mucin, and gave none of the reactions of saliva. The anatomical examination further showed that the ducts of the sublingual and submaxillary glands were in no way connected with the cyst. Upon opening this, two small accessory cysts were found in the wall, and from the anterior part of its lingual floor projected a small papilla having in it two openings pervious to the extent of a few millimetres. This papilla was the direct continuance of a small conical shaped mass of firm tissue directed towards the tip of the tongue and imbedded in its muscular substance. The microscopic examination of the cyst walls showed that there were to be distinguished: (1) an internal layer of large, cylinder epithelium, having a sharply defined ciliated border; (2) beneath this a layer of smaller, more angular, cells, with large nuclei (germinal cells), between which the sharp ends of the outer cells penetrated. Further, the walls were composed of connective tissue arranged in parallel bundles. The little core of hard tissue proved to be the remains of the proper lingual gland (first described by Blandin in 1823, and afterwards in 1845 by Nuhn) of which the outlets were dilated. The ranula is therefore to be considered as a colossal dilatation of one of the principal ducts of this gland, and originally situated in its midst.

From a most thorough analysis of the published cases the author concludes that there are to be distinguished: (1) the true ranula, as described above; (2) a dilatation of Wharton's duct, a sialoceles or ptyalocoele, to be distinguished by its cylindrical rather than spherical form; and (3) a hygroma of the sublingual bursa described by Fleischman, from which the true ranula is to be recognized by the character of its lining membrane, that of the hygroma being very delicate, and not as yet isolated.

The mucous cysts of Bartholini's glands of the vulva, and one which was found lying beneath the serous covering of the liver, were found to be essentially formed in the same manner as the ranula. Minute openings were to be seen in the walls of these cysts, and their direct continuance into the less altered gland substance could be made out. From these observations, Von Recklinghausen concludes that there is primarily a closure of one of the ducts, the secretion of mucus goes on, not from the duct wall, however, as is generally supposed, but from the gland proper, gradually dilates this duct, just as the ureters and pelvis are dilated in hydronephrosis of the kidney. Then follow changes due to chronic inflammation, the surrounding connective tissue is thickened, and the cells become transformed into a double layer, the outer of which become ciliated, these being particularly abundant in those parts of the wall richer in blood-vessels.

For the formation of such growths it is not necessary to imagine a perversion of the embryonic layer of cells,

which develop in this irregular way late in life. Mechanical irritation, to which the parts may be subjected, is sufficient to cause an inflammation which closes the outlets, and then follow the changes above described.

PRODUCTION OF CANCER BY LOCAL IRRITATION.

As illustrative of the theory that local irritation alone is sufficient for the production of cancer (epithelioma?) should be mentioned a case reported by Tillmanns.¹ It was that of a worker in paraffine, who besides a typical cancerous affection of the scrotum (similar to that occurring in chimney-sweeps) presented the appearance of a tar dermatitis on those parts of the body which came in contact with the paraffine. The scrotal tumor was removed, not to recur, but it was followed by a secondary nodule in the left arm and death after two years. The author shows that as in the case of chimney-sweep's cancer, where not all soot but that from anthracite coal seems to be the special exciting cause, so it is the workers in the brown coal tar manufactories who are especially subject to affections of the skin, varying from a simple irritation to a malignant trouble. The analogy which lies between the action of tar, soot, paraffine, and the like, upon the skin, and that of tobacco upon the mouth and lips is to be sought in the ammoniacal, empyreumatic substances which are present in all of them.

METASTATIC CANCER IN THE STOMACH.

Grawitz² calls attention to the extreme rarity of secondary cancer of the stomach, especially when its frequent occurrence as a primary disease is remembered. In a collection of fourteen hundred and seventy-six cases of cancer occurring in all parts of the body there were six hundred and nine cases of primary cancer of the stomach, or about forty-one per cent. On the other hand, he has been able to find but four undoubted cases of secondary cancer, and to these he has been able to add four more during the last two years. Joining these eight cases together he finds: (1) in four cases that it was secondary to cancer of the œsophagus; in two cases to cancer of the breast, and to cancer of the testicle and of the leg once each; (2) that in two cases the stomach contained one, in the remaining six cases, two or more nodules; and that ulcerative changes can take place in them contrary to the opinion of Forster; and finally in all eight cases the new formation was circumscribed in character. This last peculiarity may be of importance in doubtful cases in determining the secondary nature of the nodules.

FOR THE DIRECT IMPLANTATION OF CANCER

from one part of an animal to another part of the same animal, Schottelius³ gives an experiment with negative result. A bit of carcinomatous tissue was transplanted from the affected breast of a pregnant bitch to an unaffected breast, and after twenty-three days there was only found a cicatrix at the seat of inoculation without the slightest trace of the foreign substance or any product of it.

In order to find

THE RELATIONS OF THE LYMPH CANALS TO A CARCINOMATOUS GROWTH

Schottelius³ injected thirty centimetres of a watery fluid containing cinnabar into the peritoneum of a cat,

¹ *Über Teer, Russ, und Tabakkrebs*. Deutsch. Zeitsch. f. Chir. u. Gyn., 8, 549. *Centralblatt f. d. Med. Wiss.*, 1881, page 368.

² *Virchow's Archiv*, vol. lxxxvi, p. 159.

³ *Casuarische Mittheilungen aus d. Patholog. Anatom. Institut zu Warburg*. *Centralblatt f. d. Med. Wiss.*, 1881, p. 597.

whose left upper breast was changed into a hard, cancerous mass, still covered with normal skin. Peritonitis followed and the animal was killed at the end of four days. In the affected breast cinnabar could not be found, while cells filled with cinnabar were seen in two secondarily diseased lymph glands of the posterior mediastinum, both in the physiological lymph paths of the gland and in those of the cancerous nodules themselves. These particles were, however, restricted to the cells of the connective tissue and were never found in the cancerous cells proper.

Supported by observations made upon five cases, Stilling¹ is led to believe that

PRIMARY CANCER OF THE LUNG

does not start from the epithelial elements (Thiersch-Waldeyer theory) but originates in the connective tissue in or about the bronchus, as Virchow at first thought. He is forced to this conclusion rather through exclusion than by direct anatomical evidence, since the type of cancer cells which were found did not correspond either with the epithelium lining the bronchi, or with that of the mucous glands of the same; and, moreover, as their epithelium was found lying in the closest proximity to the diseased masses without showing any evidence of change. The disease could be followed in the lymph spaces of the bronchial mucous membrane, and it was chiefly through this channel that the alveoli were affected, the disease never having its origin in them. Figures are also given of the way the cancer is propagated in the lymph spaces in the intima of the arteries, and finally, how the same spaces in the sheaths of the nerves afford another means for its dissemination, while the nerve tissue itself is apparently untouched.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

S. W. LANGMAID, SECRETARY.

SURGICAL SECTION.

OCTOBER 15, 1881. Dr. R. M. HODGES in the chair.

Dr. Hodges hoped that the interest shown at the last meeting of the section, when many important subjects were discussed, would continue.

Dr. BRADFORD showed an appliance described by Dr. Morton, of Philadelphia, for

THE CORRECTION OF AGGRAVATED CLUB-FOOT,

called by him a club-foot stretcher.² This was designed as a help in the correction of the distortion after tenotomy. The immediate employment of a certain amount of force in severe cases after dividing the tendons is a procedure of no recent date. It is formally advised by Langenbeck, and Hueter, and König,³ and has probably been used by a number of surgeons, but, owing to the difficulty of fixing by the hands the os calcis and astragalus, the method has not met with much favor. Dr. Lee, of Philadelphia, succeeded by repeated attempts at *brisement forcé* (using the hands alone) in curing a severe case; little mention, however, is made in the literature of the subject of this mode of surgical interference.

In cases of aggravated club-foot the deformity is

maintained not by shortened tendons alone, but also by a contracted state of all the soft tissues. Tenotomy can divide some of these, but the ligamentous and fibrous bands which firmly unite the tarsal and metatarsal bones cannot be divided, but must be stretched or torn.

The defects of Dr. Morton's appliance are that the force applied to the foot is that of a pull through straps, which necessarily yield to a degree, and are liable to slip. The power is not absolutely under the surgeon's hand, and the machine is clumsy.

As a modification of this Dr. Bradford showed an apparatus where the power was that of a long screw similar to that in the osteoclast. The force bore upon the inner side of the foot; the os calcis and astragalus were fixed by being bandaged to a plate connected with that on which the screw worked, and also by means of a strap wound round the foot about the head of the astragalus and held by an assistant. The appliance was so arranged that besides the forcible abduction of the foot it could be twisted and flexed.

In three cases where the method had been tried it had been found that a great amount of force could be used without injury to the skin. Fibrous adhesions were felt to give way which had been firm enough to resist the force of the hands, even when the patient was etherized and after tenotomy had been freely employed.

The foot in the corrected position should be done up in a plaster-of-Paris bandage and left. The pain for the first few hours is usually severe, but after that no trouble follows from swelling of the foot. In two of the three cases where this method was used a second sitting was required.

Where a deformity of the articular facets of the astragalus exists—as has been shown by dissection to occur in a certain number of cases—perfect correction could not be brought about, but more thorough correction than is possible by tenotomy alone can without doubt be brought about by the aid of force.

Dr. CUSHING said he had somewhere seen it proposed to cut down boldly upon the contracted tissues, making an open wound.

Dr. BRADFORD said this had been done by several surgeons. He could not see the advantage of an open wound over a closed one.

Dr. CUSHING replied that it would afford an opportunity for tying several arteries.

Dr. BRADFORD said he had frequently cut arteries in the preliminary subcutaneous operations.

Dr. CUSHING spoke of the general fear of swelling of limbs to which plaster-of-Paris bandages had been applied. Dr. Bradford's experience would serve to give confidence in the application of plaster bandages.

Dr. MARCY asked why Dr. Bradford removed the bandage on the third day. He referred to Mr. Erichsen's remark that the limb never swelled if permanently incased in plaster.

Dr. BRADFORD replied that it was exceptional to remove the plaster. He did it in one case on the third day on account of pain and apprehension of sloughing.

The CHAIRMAN said it seemed to him that the rapid restoration of the deformed foot was a step in the right direction, if indeed it did not prove to be the operation of the future. The fault of the usual club-foot operation was the tedious and exacting after-treatment demanded, of which the patient and surgeon tired. An operation was certainly desirable, which would quickly and permanently bring the foot into the required position.

¹ Virchow's Archiv, vol. lxxxiii., p. 77.

² Vide Philadelphia Medical Times, October 9, 1880.

³ Lehrbuch der Speziellen Chirurgie.

DR. DE BLOIS showed a modification or improvement in the construction of laryngeal forceps for the removal of foreign bodies, also a laryngeal lancet, which will be described in some future number of the JOURNAL.

DR. ARTHUR CAROT showed a

WIRE SPLINT FOR THE TREATMENT OF HIP DISEASE, such as is used in the Children's Hospital. The advantages claimed for it are absolute immobility and extension, and yet the child can be moved. Children wearing it, even in cases of fracture, could be treated as out-patients of a hospital, or transported long distances.

One defect in hip splints, the long Dessault for instance, is that the hip drops back in them.

DR. BRADFORD said that he had seen these splints used as modifications of Thomas's splint. They were more easily made, were simple in adjustment, extension could be accomplished, and they allowed of complete immobilization of the hip-joint. It was the most simple apparatus for hip disease, the least expensive, and quite as good as Sayer's wire cuirass or Thomas's splint.

DR. MARCY exhibited and explained the principle of the "Evans mercury-sealed trap" for water-closets.

He also showed some specimens of the material used by him for antiseptic dressings. He said that most cotton cloth was clean and devoid of dressing or filling of earthy or other matter at some stage of its manufacture, and it was cloth in this stage of manufacture which he used. Dr. Marcy also showed some ligatures made of carbon tendon.

DR. GAY spoke of the use of cosmoline in place of paraffine in antiseptic dressings, whereby the gauze was rendered less stiff.

It was voted that the section should meet every six weeks, alternating on the first and third Saturdays of the month. Adjourned.

PROCEEDINGS OF THE GENERAL CENSORS' MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY.

NOVEMBER 17, 1881. Meeting called to order at two p. m., and call read as follows:—

"At a meeting of the Councilors of the Massachusetts Medical Society, held June 7, 1881, it was voted:—

"That the Secretary of the Suffolk Board of Censors, acting for the parent society, invite all the censors of the several districts to meet either with full boards or by delegates, for the purpose of considering the advisability of effecting a permanent arrangement, under which there shall be held at stated intervals, a conference at which delegate censors, one from each district of the State, shall discuss those questions in which they have a common official interest, and thereby secure, as far as is practicable and necessary, a uniform standard of examination for the whole State."

Dr. Thomas Dwight was elected chairman, and Dr. H. C. Haven clerk of the meeting.

DR. W. S. BROWN, of Stoneham, thought the first question to be considered was: "Is *any* examination desirable?" the only object of it is to keep candidates from gaining admission in any underhand way. A dozen years ago nothing but a diploma from a recognized medical school was required; now some boards

require no more, some much more; Dr. Brown expressed himself strongly in favor of a practical examination, as nearly uniform as possible, and only raised the question for the purpose of eliciting discussion.

DR. E. P. HURD, of Newburyport, thought it desirable that some uniformity should be maintained, even if it were not absolute. That some examination should be required he thought a foregone conclusion. Dr. Hurd stated that in Essex North District an examination had, for the last year, been insisted on; and the censors had been subjected to much criticism on account of their having rejected certain applicants who did not seem to them to possess the requisite qualifications.

DR. NICHOLS thought the only object of the meeting was to find out if we should insist on a uniform examination. If this were desirable the question of the means best adapted to secure it could be better decided by some permanent organization.

DR. G. K. SABINE, of Brookline, said that he was present as an individual member of the Norfolk board, and, therefore, could not vouch for opinions of his colleagues, but that he personally was strongly in favor of there being at least some guide to the different boards in their interpretation of the By-Laws.

DR. F. C. SHATTUCK, of Boston, thought that a great deal of good would arise from a yearly interchange of opinion between the several boards, even if no absolute uniformity was attained. He thought it essential that the censors of different districts should know the general methods of other boards; and that a yearly meeting would do much to bring all the boards into practical harmony.

DR. DUDLEY, of Plymouth, asked for the reading of the By-Laws relating to the necessary qualifications of candidates, and the method of admission. These are as follows:—

"FELLOWSHIP.

"1. Every candidate for admission into the Massachusetts Medical Society must, by proper credentials and examination, satisfy the censors of said Society that he possesses the following qualifications for fellowship:—

"That he is not less than twenty-one years of age; that he is of sound mind and good moral character; that he has a good general English education; that he has a knowledge of the principles of experimental philosophy; that he has such an acquaintance with the Latin language as is necessary for a good medical and surgical education; that he has studied medicine and surgery three full years under the direction, and attended the practice, of some reputable, regularly educated physician or physicians; that he has attended two terms of study, or two full courses of lectures in separate years, at an authorized medical school, recognized by the Councilors of said Society, and possesses a diploma or its equivalent from such school; that he does not profess to cure diseases by, nor intend to practice, spiritualism, homeopathy, allopathy, Thompsonianism, eclecticism, or any other irregular or exclusive system, generally recognized as such by the profession or declared so by the Councilors of said Society: and, by a further examination, a part of which shall be in writing, that he has an adequate knowledge of anatomy, pathological anatomy, physiology, general and medical chemistry, materia medica, therapeutics, midwifery, the theory and practice of medicine, clinical medicine, surgery, clinical surgery, hygiene, and public hygiene."

DR. DUDLEY then said that it would seem that the

several boards had not been justified in admitting a candidate on his diploma alone, and that, instead of those boards who had instituted a reform deserving praise for so doing, they should be censured for not having done it before.

The following resolution was proposed by Dr. SHATTUCK, seconded by Dr. SABINE, and unanimously adopted:—

Voted, That in the opinion of this meeting it is expedient that the requirements of the By-Laws with regard to the examination of candidates for admission to the Massachusetts Medical Society be universally observed in the various district societies.

Also voted, That the secretary of this meeting be instructed to request the Board of Censors of each district to appoint two delegates to attend an annual meeting for conference to be held in Boston on the second day of the annual meeting of the parent society.

Dr. NICHOLS moved "that the chairman and secretary of this meeting be authorized to request the council to initiate such a change in the By-Laws as may make this annual meeting of the delegate censors obligatory. The motion was duly seconded and carried.

Dr. HAVEN thought that one reason for the great discrepancy in the interpretation of the By-Laws regarding membership was that so much of it is obsolete it is impossible to accept it literally, and this opens the door for individual differences of opinion as to what portions of the law should be regarded; an unenforced law is demoralizing, and this By-Law if enforced would result in the rejection of almost every candidate. If the censors had a law they could literally follow in every respect but that of the severity of examination there would be little difficulty in obtaining a practically uniform standard by means of the annual meeting. He therefore moved "that this meeting do petition the councilors of the Massachusetts Medical Society to consider the question as to whether By-Law I. does not require revision in order that it may be accepted as a literal guide for the several censors' boards." After being duly seconded the motion was carried.

Adjourned *sine die*.

BIOGRAPHICAL SKETCHES OF DECEASED MEMBERS OF THE OBSTETRICAL SOCIETY OF BOSTON, WITH AN OUTLINE OF THE EARLIER OBSTETRICAL HISTORY OF BOSTON AND VICINITY.¹

BY WILLIAM W. WELLINGTON, A. M., M. D. (HARV.),
Member of the Society, etc., etc.

Dr. WALTER CHANNING, the first professor of midwifery in Harvard College, was born in Newport, Rhode Island. His parents and ancestors were people of high social and intellectual position. His elder brother, Rev. William E. Channing, D. D., has a world-wide reputation. Hundreds of Harvard graduates bless the memory of a younger brother, Prof. Edward T. Channing, for his admirable professional work in the chair of Rhetoric at Harvard College.

Dr. Channing's name appears in the Harvard College catalogue among the graduates of 1808. He pursued his medical studies in Boston, Philadelphia, Edinburgh, and London. He established himself as a

physician in Boston in 1812, at the age of twenty-six years. Three years later he entered upon the duties of his professorship.

My first knowledge of, and acquaintance with, him began in the autumn of 1835. He was then in his prime. In the department of obstetrics he stood without a rival in this neighborhood. I shall never forget the impression made on me by his first lecture. I had just begun my medical studies, and was attending my first course of medical lectures. According to the custom of the time, for four months, from November to February inclusive, we were required to listen, from four to six hours each day, to lectures on all the branches of medicine, and to digest what we could of them. The lectures (those on chemistry excepted) were good, but to a young beginner not at first specially interesting. It was Dr. Channing's turn to officiate on the second hour of the second day. He came fresh from his morning's drive, bright, cheery, and in the best of spirits. The first impression was a favorable one. He was a fluent, at times an eloquent, speaker. He graphically described the bones of the female pelvis, and clothed them with flesh and blood; he was full of fun and anecdote; his manner was pleasant and interesting. The lecture reminded one of a refreshing easterly breeze in a dry, hot summer's day. The hour passed rapidly away; he briskly put on his coat, and disappeared as suddenly as he came, leaving us almost spellbound.

It is "due to the truth of history" to say that the promise of this first lecture was hardly fulfilled in the sequel. As the course proceeded the lectures were apt to be discursive. The doctor was rarely tedious; but he was erratic, and not always edifying. In time we began to listen to John C. Warren, John Ware, George Hayward, and Jacob Bigelow, with at least as much interest as we did to the professor of obstetrics.

Once or twice during the course we were treated to a little practical midwifery. A female pelvis was placed upon the table. The head of a rag baby was thrust into it. It was our duty to ascertain the presentations, and to deliver with the forceps. The scene in such a lying-in room may be imagined.

Dr. Channing had thoroughly studied the art which he professed to teach. He was an enthusiast in obstetrics, and was held in high regard as a counselor in this department. He made many contributions to the literature of our profession, and delivered one of the annual discourses before the Massachusetts Medical Society. His book on Etherization in Childbirth was timely and valuable. His paper on the Bed-Case is worth reading to-day.

He was connected for more than twenty years with the Massachusetts General Hospital, and was one of the accoucheurs of the Boston Lying-In Hospital.

It is to his credit, as well as to that of the donor, that he received a bequest of several thousand dollars from a lady whom he never saw but once, but then in an hour of extreme peril, and who believed that to his skill she owed her life.

He was one of our earliest members, and as our first president is well remembered. He was much interested in this Society, usually attended its meetings, took an active part in the discussions, and was always bright, genial, and kindly.

Dr. Channing was a religious man, and deeply interested in religious institutions. When his pastor was absent he would conduct the service and preach

¹ Concluded from page 497.

the sermon. He could preside over a Bible class, consisting of fifty to a hundred men and women, on a Sunday afternoon. He was willing to aid in parish work; and, though full of practice, would devote a generous portion of his time to parochial duties.

He lived to be ninety years old. During the latter part of his life the increasing infirmities of age kept him secluded. I have been told that he and his younger brother, in their last years, were in the habit of passing their birthdays together, and of devoting the time to social intercourse, to the reading of the Scriptures, and to prayer. He served well his day and generation; the close of his life was calm and peaceful; he has left behind a pleasant memory.

Dr. Charles G. Putnam was born in Salem. He graduated at Harvard College in 1824, and received his medical degree from the same institution in 1827. After practicing a few years in Salem he removed to Boston. He gave special attention to obstetrics and the diseases of women.

His life was not an eventful one. He never obtruded himself into public notice, or sought to occupy conspicuous positions. Quiet, modest, and unassuming, he devoted himself unreservedly to the discharge of his duties as a physician. He possessed a clear head, a kind heart, and a sound judgment. He was a loyal, active, and faithful member of the profession, which he had thoroughly learned, and which he ably and conscientiously practiced.

The Massachusetts Medical Society, appreciating his worth and merits, in 1869 made him its president. Upon the resignation of Dr. Channing this Society with one voice chose him to fill the vacant place.

He died suddenly, February 5, 1875, aged seventy years. His last words, while seated on the doorstep, just after the attack which proved fatal, were a request to his son to visit a patient who required immediate attention.

At a special meeting of the Suffolk District Medical Society, called to notice his death, resolutions were passed in honor of his memory. Remarks were also made by several physicians attesting to his excellence of character, his independent judgment, his kindness of heart, and his devotion to professional work. Mention was also made of his dexterity as an operator in obstetrical cases, and of the kindness and skill always manifested by him when called in consultation. In the language of one of the speakers, "He was a wise, thoughtful, genial, gentle, man. All of us must be better for the example his life has been to us."

Dr. Anson Hooker, our third president, was born July 17, 1799, in Westhampton, Mass. He graduated at Williams College in 1818, and at the Harvard Medical School in 1822.

He began his medical career at the south end of Boston, and for a time had charge of a dispensary district. He removed from Boston to East Cambridge in 1825, and from that time till his death in November, 1869, he was an active and devoted physician.

Dr. Hooker was a man of high character, and of more than ordinary ability. His life was a laborious one, but he was enthusiastic in his love of his profession, and performed its every duty with conscientious fidelity. He had a genial and cheerful disposition, was eminently social and domestic, and carried sunshine wherever he went. His reputation was good in all branches of the profession; in midwifery he was an expert. His obstetrical practice was very large. Those

who have examined his account books report that they find in them a record of about ten thousand cases of labor. His skill in obstetrical operations was proverbial.

During the war he was specially detailed, by order of Governor Andrew, to visit, and report upon, the condition of the Massachusetts soldiers invalided in the Western United States general hospitals. He performed this duty in a very satisfactory manner, and received the thanks of the governor for the service rendered.

Dr. Hooker was regarded by the community in which he lived not only as the good physician, but as the wise counselor and the kind friend. At various times he was called to fill important offices of trust and responsibility. He served upon the Board of Aldermen and School Committee of Cambridge, and for two years represented the city in the legislature.

His death, at the age of three score and ten years, was caused by disease of the heart. The scene at his funeral was impressive. The church in which the services were held was crowded, and the countenances of those present indicated clearly the sadness of their hearts. Places of business were closed, and the whole population seemed to unite in offering a last tribute of affection to one whom they loved and honored. A fitting monument has been erected to his memory by the contributions of his townsmen.

Dr. Charles E. Buckingham graduated as Bachelor of Arts at Harvard College in 1840, and as Doctor of Medicine in 1844. He was the son of Joseph T. Buckingham, the noted editor of the *Boston Galaxy* and subsequently of the *Boston Courier*, and he inherited some of his father's peculiarities. He began practice in Boston soon after he received his medical degree. He was a man of ability, energy, and industry. Independent, candid, outspoken in the expression of his opinions, honorable in his relations with his professional brethren, and possessing a generous regard for those who were his juniors, he gradually overcame the obstacles which lay in his path, and took and maintained his position as one of the leading physicians in Boston. But while ready and willing to accord to others their full rights, he was not inclined to relinquish his own without a struggle. He was not a non-resistant; whoever wished to contend with him found a foe man worthy of their steel.

His character and abilities received due appreciation both from the profession and the public. He received successively the appointment of surgeon and consulting physician of the City Hospital, and of adjunct professor of the theory and practice of medicine and of professor of obstetrics and medical jurisprudence in Harvard University. He labored assiduously to raise the standard of medical education, and heartily sympathized with the late movement to reorganize the medical department of Harvard University.

As a writer he was clear and vigorous. It is understood that at the time of his death he had made considerable progress in the accumulation of material for a treatise on obstetrics.

He was an interested and valued member of this Society, and, as its president for three years, did much to quicken its activity, and give life and character to our meetings.

He died at the age of fifty-six. A large company of those who loved and confided in him filled the church in which the funeral services were held, and united in rendering to him a last tribute of respect.

Channing, Putnam, Hooker, Buckingham,—our first four presidents; they honored their profession while living; lovingly we cherish their memory.

Although Dr. John Homans had ceased to be connected with this Society before his death, yet our pleasant recollections of him will not allow us to pass him in silence. He graduated at Harvard College in 1812, and began his professional life in Brookfield, Mass. After several years of successful practice in that town he removed to Boston, where he soon took, and for forty years maintained, a place in the front rank of his profession. He was a man whom it was pleasant to meet, and with whom it was a privilege to be acquainted. Courteous and gracious in his manners, kind and genial in his nature, thoroughly devoted to his profession, he won for himself a high place in the public estimation. He was for two years president of the Massachusetts Medical Society, and in 1844 delivered the annual discourse. In his own life he exemplified the "Good Physician," whose character he so pleasantly portrayed in his discourse. He died in 1868, aged seventy-four years.

Many of us retain pleasant recollections of Dr. Edward D. G. Palmer, of Boston, a man of quiet and unassuming manners, respected and esteemed by his professional brethren and his patients.

Dr. William Edward Coale was a native of Baltimore, and a graduate of the University of Pennsylvania. For several years he was an assistant surgeon in the navy, and for twenty-two years was a practitioner in Boston. Coming here a stranger, he soon had patients and friends, who appreciated his ability and acquirements. He was an early member of this Society, and was esteemed for his social qualities and his medical attainments. In 1862 he offered his professional services to the government, and was in service for several weeks in the memorable campaign of the Army of Virginia. Obligated by sickness to return home, he went back to the work in November of the same year, and visited the military hospitals in Tennessee and Kentucky as an inspector of the Sanitary Commission. He contracted disease in those malarial regions, from which he never recovered.

He was for many years an officer in the Massachusetts Medical Society, and an instructor in the Harvard Medical School. He was the author of a little work entitled, *Hints on Health*, very pleasantly written, and full of valuable suggestions on a variety of subjects. He was a good physician, and a genial, true-hearted man. He died suddenly in April, 1865.

Dr. Calvin G. Page died May 29, 1869, at the age of thirty-nine years. He finished his work in early manhood, a work marked throughout by energy, integrity, and fidelity to every duty. He was a man of great worth, and respected and beloved by those who knew him. He served honorably through three years of the war, and his early death was owing, in part at least, to exposure during this service. He died on Decoration Day, while loving hands were strewing flowers on the graves of his departed comrades.

Dr. Lucius M. Sargent was personally unknown to me. I knew him only by reputation. He was one of the youngest, perhaps the youngest, of our number. He was the first to die.

He was born in Boston, September, 1826. He entered Harvard College in 1844, but left during his second year. He received, however, the degree of Master of Arts with his class, as a special compliment to

his general attainments, and the zeal and ability with which he prosecuted his profession. He was always among the foremost where energy, talent, and courage were necessary. As a medical student his application was unremitting, and his enthusiasm was unbounded. The Hospital created the office of Artist to secure his services. After his graduation he soon became a prominent physician in the section of the city where he established himself, and a brilliant future seemed opening before him.

On the breaking out of the rebellion, he promptly offered his services as surgeon in the Second Massachusetts Infantry. But the routine of a surgeon's life soon became too dull for him, and he resigned his medical commission. He was next appointed captain in the First Regiment of Massachusetts Cavalry, and was in a large number of skirmishes and dangerous movements peculiar to cavalry service. He rose in course with meritorious conduct to the rank of lieutenant-colonel.

On the ninth of December, 1864, while gallantly leading a successful charge upon the outer works near Bellfield, Virginia, under orders to "drive the enemy within his main defenses, and to determine the rebel position," he fell in front of his mounted column, mortally wounded, and in two hours expired.

"How sleep the brave who sink to rest,
By all their country's wishes blest!
By fairy hands their knell is rung;
By forms unseen their dirge is sung;
There Honor comes, a pilgrim gray,
To bless the turf that wraps their clay;
And Freedom shall awhile repair
To dwell a weeping hermit there."

Twenty years have elapsed since the formation of this Society. During this time nine of the members have died, including one who had previously resigned membership. The duty was assigned me, by the President, of recalling them to your memory, and of briefly sketching their lives and characters.

This duty, reluctantly assumed and unsatisfactorily discharged, has nevertheless been pleasant in performance; the more so from my connection in the service with one whose friendship and sympathy I have shared through all my life.

It was a privilege and an honor to be associated with these men:—

Terra tulit.

GYNECOLOGICAL SOCIETY OF BOSTON.

STATED MEETING, FIRST THURSDAY OF SEPTEMBER,
1881.

HENRY M. FIELD, M. D., SECRETARY.

WM. G. WHEELER, M. D., president, in the chair.
DR. FIELD read by appointment a paper entitled

REPORTS FROM GYNECOLOGICAL PRACTICE OF 1880
AND 1881,

of which an abstract follows:—

The first case related to a lady about thirty years of age, who had been married ten years, and lived constantly with her husband; both of good health. Had never been pregnant. An investigation had been proposed several times by the doctor and declined, until the occurrence of pain and engorgement in the left breast, which refused to yield to the usual measures of treatment, both created a present demand and afforded

the occasion long desired for a uterine examination. Local symptoms now, as heretofore, almost wholly negative. The womb was found healthy in all particulars except that the cervix was elongated and so bent upon itself that the os presented towards the sacrum. A simple gutta-percha ring was introduced with effect to restore cervix to its natural position, and this the patient wore without irritation. The purpose and hope implied in this procedure were fully explained to both husband and wife.

Pain in the breast began speedily to diminish, and engorgement, more slowly, disappeared. Two or three months later husband called for some measure of relief of severe nausea of pregnancy. Supporter was removed after the fourth month, pregnancy proceeded safely to its full term, and patient was recently delivered of a female infant.

The second case had to do with a local condition almost exactly the same; patient had been married several years, and had had several miscarriages, in an early stage of gestation, which had doubtless been more or less encouraged; was now, however, desirous of having a child. Little or no local discomfort, but varied and extreme reflex distress, chiefly characterized by insomnia, nervous restlessness and irritability, and especially by pain in the region of the heart, with attacks of palpitation on occasion of more than usual fatigue. Indeed, she had been led to consult a physician because of her belief that she had heart disease. The same kind of supporter as was used in the first case equally well corrected the local mal-position, and very general constitutional relief followed. Earnest moral advice was given, and was greatly needed, patient being urged to give up her life of excitement and general moral dissipation, to which she was accustomed, and live as a sensible woman should. Pregnancy was represented as an end to be attained if possible.

Reported at the end of three months that she was greatly relieved in all respects, and much pleased with the results of the treatment: was evidently trying to carry out her part in the effort to recover her health. Reported again a short time since — nine months from commencement of treatment — that she was no better than at first, had lost the ground she had gained, was discouraged. Had evidently returned to her old methods of life, — had rejected the doctor's advice that she should live as much as possible with her husband, and had been away from him as much as possible. Thought the supporter was causing irritation.

Result of treatment in this case a failure. Supporter was removed, although there was no sign of local irritation, and case abandoned, which it was easy to do as patient lived at a distance of several hundred miles. Can see no valid reason why the second case might not have been as successful as the first, but in gynecology, in an eminent degree, as in other departments of medical practice, but little can be done unless the patient faithfully and intelligently cooperates with the physician.

The third case had to do with a married lady, rather above thirty, who, after several miscarriages and a birth at full term, after repeated threats of miscarriage, and the loss of her child in infancy, possessed of a morbid desire to become a mother, reported herself in a family way, and tormented with a fear that her hopes would again be blighted by abortion. Early in gestation a slight sanguineous flow showed itself, which only ceased when the patient kept her bed. Later remaining in

bed afforded no security, and the flow gradually increased in quantity in spite of all measures to arrest it. Examination about this time disclosed a considerable erosion about the os and an appearance like slight fissure to the left of the uterine orifice. If these could be cured it was believed the flow would cease, and the patient be safe. Tannin suppositories were tried for a time, and, later, careful local applications of iodine and balsam Peru. The latter seemed to promise a partial success for a time, but suddenly, as patient was approaching her sixth month, labor pains set in, and a viable fetus was extruded. Nothing about child or placenta appeared abnormal.

Patient was carefully watched, and it was intended that local applications suitable to the case should be made as early as possible. But soon after — two weeks — a tendency became apparent by which the erosion and fissure were being gradually drawn within the cervical canal, so that at six weeks after parturition nothing abnormal could be found, whether by examination by speculum or sound. The belief was expressed, however, that should this patient again become pregnant within a year or year and a half the old lesions would reappear, similar symptoms be reproduced, and she would have the same sad ground to go over again.

The fourth and last case reported was to the following effect. Mrs. L., aged thirty-five years, had had several children and one or two miscarriages. Her last confinement was at full term, and about four years prior to the beginning of this record. Had had then a bad getting up, but had gradually recovered her accustomed health. In April, 1880, consulted the doctor for great menstrual irregularities and general ill health, which she referred to this cause. Called several times upon the physician between this date and November, when she declared herself in no way improved. Had begun to menstruate ten days before, and flow seemed much like that of old times; but it suddenly ceased after two days, and left her feeling rather worse than before. Appointment made for a local examination at her home the next day.

Examination by conjoined palpation gave no results, owing to firmness of abdominal walls and thickness of adipose. Having been again catechized as to possible pregnancy, she was placed in position favorable for passage of sound, and this instrument passed to a depth of four and a half inches, the last two inches with extreme caution. Sound appeared finally to impinge upon fundus of the uterus; no obstruction occurred at any point, no pain occasioned, and no discharge followed withdrawal of instrument. Special cautions given the patient and decision reserved. The following night she was seized with severe labor pains, and a few hours later the decayed remains of a fetus and membranes of apparently three months' development were extruded, in such a state of decomposition that no possible measures of deodorization and disinfection could remove the smell from the room for several days. Patient made a good recovery.

With memory thus assisted, herself and husband recalled the circumstance that rather more than a year before she had been suspected of pregnancy on account of certain symptoms, but these soon and completely disappearing the experience had wholly passed out of mind.

The reader remarked upon this case the phenomenon of a decayed fetus having been so long retained

without any effective efforts on the part of the uterus to cast it off, and with so little local disturbance that suspicion of its presence had never been once, through the whole year, entertained by the patient. The absence of all septic infection was also worthy of remark when we remember with what fatal facility, under circumstances apparently of much less provocation, toxic material is taken up by the uterine veins and sinuses.

DR. HUNT, of Newtonville, — present by invitation, — remarked upon the tolerance which the uterus will show for bodies not living and for dead matter generally, whereas it creates, oftentimes, a great disturbance about a living fetus. Recall but a case of pregnancy, complicated by albuminuria and Bright's disease in their last stages; immense swelling over the whole body and difficult respiration, could not bend the legs on account of swelling; moreover, persistent head-symptoms like those which precede convulsions. All at once came a period of complete and universal comfort: head-symptoms abated, a great flow of urine occurred without further diuretic interference, all œdema and anasarca disappeared; but synchronous with this general relief was a stage of uterine calm, all fetal motion had ceased, and three weeks later the womb cast off an ovum of seven months' development, dead and considerably decomposed. So long as the fetus is alive we have all sorts of trouble; the moment life ceases all bad symptoms disappear. We should have expected the opposite of this, that is, that the dead fetus would make the trouble. Has had an experience like this at least three times. Had never seen mischief from anything retained within the uterus so long as it was dead; no contamination of the system.

DR. WHEELER recalled a case of placenta retained three months; no unpleasant symptoms till just before expulsion. Dilated and supposed he had to do with a broken-down fibroid or detached polypus; no septic effect.

DR. FIELD remarked such testimony had the most direct bearing upon the question of what to do in case of retained placenta and like conditions. Some physicians are never easy till they have removed the dead matter, at whatever cost of effort and of discomfort to the patient. If there is no danger of septic absorption, assuredly we should leave the patient to nature's measures indefinitely, so long as she is comfortable otherwise. He would like to ask, however, why is it the patient is safe under these circumstances? why are the uterine veins and sinuses, which appear to be hungry for septic matter after a normal parturition, so that many advise and practice carbolic injections, often repeated, and continued for a considerable time as an antiseptic measure of protection, why are these same veins and sinuses practically closed against all possibility of absorption while yet the uterus contains, for months together, a mass of corrupt and putrefying material?

DR. MARCY replied he believed no explanation of this was possible except in the light shed upon this whole subject by the researches of Ercolani. With the text and diagrams of this author before him he commenced an elucidation, which, however, was of such extent and interest that, upon motion, the discussion was waived until the doctor should find time to write a paper upon the subject.

DR. NORRIS reported the case of a lady who had been married nine years and had never had a child.

Examination showed the cervix conical, elongated, and bent on itself. A ring caused too much irritation, but the substitution of a Grailly Hewitt eradle worked well. This the patient wore comfortably for four months, and a year later gave birth to twins.

DR. STODDARD would ask Dr. Marcy if we are to understand that nature affords protection to the woman, in whom a fetus dies, above that afforded to her who produces her child at full term, in respect of liability to, and immunity from, the absorption of septic material.

REPLY. Both are protected until the serotinal cells are removed. During the ninth month cretaceous and fatty degeneration sets in, evidence of which all have seen in the chalky points visible in the placenta examined after birth; and this is nature's method of removing what would otherwise interfere with effective contraction of the uterine muscle at time of parturition.

DR. STODDARD wished to ask Dr. Field if there was elongation of the cervix in the first case reported; also what was the chief factor in the production of flexion, was it flaccidity alone or was it prolapsus.

The Chair replied, we are apt to find the elongated, cone-shaped cervix bent upon itself. Baker Brown, in the days of his prominence, suggested partial amputation as a remedial measure. More lately, a method palliative rather than curative has been accepted; obviate the mischief as much as possible by raising the uterus by some measure of support, and by changing the axis of the canal. Had himself secured pregnancy by such change of position, with or without the aid of repeated dilatation.

DR. NORRIS rejoined that the instrumental measure was far from being his sole dependence in this class of cases. He further gave especial attention to all calculated to raise the tone of the general system and so promote local tone, for example; in the case reported, he had insisted the husband should remove the patient from a cellar-basement into rooms of better elevation, and where a sufficiency of light and pure air could be obtained.

DR. W. S. BROWN remarked, in further allusion to Dr. Stoddard's question, that Huguier first pointed out that what was formerly regarded as prolapsus is simply elongation with hypertrophy and flaccidity. In this condition, the entrance of the male organ tends both to maintain and increase the flexion of the cervix and the presentation of the os towards the cervix.

Discussion followed at some length respecting measures calculated to prevent repeated abortion, in the third case reported, in which Drs. Wheeler, Hunt, Brown, and Field, chiefly took part.

DR. W. S. BROWN advised that the cervix should be dilated by sponge-tent, protected by slips of slippery elm, in order to ascertain if there was actual disease, and, if so, its exact location; in the event of the discovery of which the usual measures should be taken for its removal.

W. P. GIDDINGS, M. D., of Gardiner, Me., was unanimously elected a corresponding member. Society adjourned.

— The British Health Congress, to which will be attached a domestic and sanitary exhibition, meets in Brighton December 13th, under the presidency of Dr. B. W. Richardson, who will inaugurate the Congress with an adress. The exhibition will open December 12th.

Medical and Surgical Journal.

THURSDAY, DECEMBER 1, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.

HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

RUDOLPH VIRCHOW.

On the 13th of October, Rudolph Virchow completed the sixtieth year of his life and the twenty-fifth of his professorship in Berlin. The event has been marked, not alone by the private congratulations of his friends throughout Europe, but also more publicly by two festivals, the one held in the Pathological Institute on the 13th of October, the other in the Rathaus on the 19th of November. The former was especially of a medical character, consisting, as it did, of a gathering of many of Virchow's earlier assistants, together with a few of the more noted medical men of Germany, the latter was of a more general scientific character. The special feature of the meeting at the Institute was the presentation, by his pupils, of a bust of Virchow to the Institute and to himself, and of an album containing their own photographs. The presentation speech was made by Recklinghausen, Virchow, in response, giving a short sketch of the Institute and its work. In the evening Virchow's friends joined him at a dinner. The celebration of the 19th of November consisted of a fête in the Rathaus attended by a thousand or more of the scientific and medical world. The object was the presentation to Virchow of the keys of the "Rudolph Virchow Stiftung," a new Anthropological Institute, of which Virchow is to be director. The money for this purpose, amounting to seventy thousand marks, had been raised by subscription in the various European countries.

Virchow may indeed feel proud of the testimonials that he has received from all quarters on this anniversary, and, in turn, Germany and the world do rightly in honoring a man who has done so much, not alone for medical science, but also for anthropology, archeology, and political science, in all which he has been hardly less eminent than in medicine. His career may be said to have begun in 1846, when he succeeded Robert Froriep as professor of the Charité in Berlin, this giving him control of the ample material afforded by this hospital.

Of his earlier life a word only is necessary. Born in Schivelbein, in Pomerania, in 1821; graduated from the University of Berlin in 1843, the favorite pupil of the physiologist Johannes Müller, he became an assistant to Froriep in the autumn of 1843, and in 1846 professor. It was in this year that he began the investigations which have placed his name so high among medical scientists. Starting with the idea that pathological physiology constituted the basis of the

science of medicine, and that anatomy and the clinic were its annexes, he began in 1847 his teaching, having in that year been made Privatdocent.

A glance at the work of his predecessors may be of advantage as showing that the ground had already been broken for him and that the results of his investigations, though brilliant and original, were yet in a measure the further development of what had been done before his time. Already had Andral and Cruveilhier, by the observation of facts, completely overthrown the purely speculative system of Broussais, which had gained the approval of the medical world, embracing, as it did, his doctrines of the "Phlegmatics Chroniques," a system which regarded the stomach as the point of origin of all diseases, pathological changes elsewhere being but secondary manifestations of the gastric disturbance. Already had Schleiden discovered and published the fact that the cell is the unit of plant life, and Schwann had done the same for animal life. Johannes Müller had published his work on the finer structures of tumors, thus giving a basis to pathological histology, and Rokitauský had given to the world the results of nearly thirty years' careful observation and classification of the unrivaled material of Vienna, valuable for the gross pathology but marred by the prominence given to the views of humoral pathology. So much of preparatory work had been done when Virchow began his career,

Early recognizing the importance of studying the finer changes presented in pathological tissues, he appreciated more fully than any of his predecessors the value of the microscope, and he appreciated it, too, in a different way, for, excepting, possibly, J. Müller, all had been satisfied to apply it in the study of changes which were already completed; Virchow, however, put it to a far more valuable use in that he sought with it to follow out the *development* of the pathological process in detail. The abundance of original material resulting from the application of this method led him, in conjunction with Benno Reinhardt, to found, in 1846, the Archives of Pathological Anatomy, the first volume of which appeared in 1847. The joint editorship lasted till the death of Reinhardt, five years later, most of the articles being written by them, with some assistance from Leubuscher. Since Reinhardt's death Virchow has been sole editor of this monument of German industry, now arrived at the eighty-sixth volume. An active mover in the outburst of republican sentiment which swept over Germany in 1849, he lost his positions, and, though afterward reinstated, he accepted the professorship of pathological anatomy in Würzburg, a place which has well earned for itself the title of the cradle of Germany's great men. Here he remained six years, and of the amount and value of his work one can get no better idea than by looking through the Transactions of the Würzburg Medical Society, which he founded, and of which he was at first secretary and then president. His Collected Treatises, published in 1856, contain several of his more important earlier papers. In 1856 his reputation had become so widespread that in spite of his well-known liberal political views, he was re-

called by the minister, Manteuffel, to Berlin as professor of pathological anatomy, and also made director of the new Pathological Institute and physician to the Charité. Here he has since remained, and to give an idea of his work is almost to give the history of pathology during this period. In referring to the more important points only, it may be said that his work with the microscope early showed him the importance of the cell as the unit of life, as already demonstrated by Schleiden and Schwann, but he studied further into the origin of cells than either of these authors, and showed that they were wrong in their supposition that cells could form by the conglomeration of granules in a blastema, the so-called "free cell formation." He proved conclusively that every cell must come from a preëxisting cell, and hence arose his oft-quoted saying, "*Omnis cellula e cellula*." Following further the cell theory of Schwann, who, in his studies on the development of single tissues, had shown that all physiological activity was to be referred ultimately to the cell, that the seat of life is in the cell, and that for the manifestations of life under normal conditions one must look to the cells — starting with this as proved, Virchow applied to the cell in its pathological relations what Schwann had done in its physiological relation, and showed that what is called disease is simply the result of a modification of the cellular activity, caused by something outside, be it physical or chemical, and hence pathological manifestations should be referred back to the cell just as physiological are. This constitutes his famous Cellular Pathology, the ground-work for which was given in articles in his Archives, and later, in 1858, in full in the form of lectures, which were printed, and which make a book worthy of being ranked with Morgagni's *De Sedibus et Causis Morborum* in its influence upon pathology. The Cellular Pathology has replaced the humoral and solidistic pathologies, and by it most, if not all, pathological phenomena which have been thus far investigated have been explained.

In 1863 appeared the first part of the treatise on tumors, the publication of which was continued, at intervals, till 1867. Although not completed, for the carcinomata yet remain to be considered, the work is of great value. The method of classification developed by Virchow, which arranges new growths according to their anatomical structure, if not perfect is nevertheless the best that has yet been devised, and the amount of original material given in these volumes is remarkable.

In regard to Virchow's position with reference to experimental pathology, it may be said that he was a pioneer in this method of investigation, and fully proved its great value in his work on Thrombosis and Embolism. Of the numerous subjects on which Virchow has given to the world so much real knowledge there may be mentioned the work on Leucæmia, Pathological Pigments, Blood Crystals and their Import in Forensic Medicine, Endocarditis, Endoarteritis, Cretinism, Rachitis, Amyloid Degeneration, Corpora Amylacea, and Parenchymatous Inflammations. His classification of disease and his nomenclature, having as

they do an anatomical basis, form the most truly scientific ones that exist, and are now almost universally used.

Of late years Virchow's multifarious duties have prevented his devoting so much time as before to students in the laboratory, and for this reason many, certainly among Americans, prefer to study elsewhere. Nor has he given to the world the results of medical investigations so freely as before. But nevertheless he deserves the credit for what is being done in pathology to-day, for the best workers in Germany are those whom he himself has trained, and who now follow out his methods, not alone in their original work, but also in teaching and training those who are to come after them. Truly this is a master mind and its influence will be felt as long as pathology is studied. Well may its possessor say of himself with Horace, —

"Exegi monumentum ære perennius."

MALARIA IN WASHINGTON.

THE medical profession in Washington have risen in indignant response to the bad names by which their abiding place has been called, and have issued circulars to all practicing physicians within the District of Columbia, to collect such statistics as will enable them to answer and refute these epithets so dangerous to a good reputation.

Washington is surrounded on three sides by sluggish streams of water; the broad Potomac in front and to the south, the Eastern Branch to the east, and Rock Creek to the west, it stretches northerly and in a northwest direction to an elevated upland country; at the foot of this rise was once an extensive marsh, and running through the city were once a number of little creeks and streams. Not much more than fifty years ago the city newspapers complained of the carelessness of gunners for ducks and other birds in the neighborhood of Pennsylvania Avenue, near the Capitol building, a lady being injured by stray shot while taking her afternoon promenade on this the principal street. All of these localities were infested with malaria, but now the marsh has been drained, the creeks and streams have been utilized for sewers, and the draining and paving of streets have made malaria at these points a thing of the past, and some of the handsomest houses in the city have been built upon them. Rock Creek is so situated as to cause but little trouble, its banks are used for business purposes, and it too may some day serve for the building of a vast sewer. Far to the eastward lies the Eastern Branch, more malarious perhaps than it ever was, with vast marshes, the feeding ground of the duck, reed bird, and ortolan, but it is too remote from dwelling-houses to exert active influence upon the residents of Washington, and expends its force upon the inmates of the jail, workhouse, almshouse, and city hospital, thus lightening very materially the burden of the city authorities. But there remain along the city front the broad flats and marshes of the Potomac, the best view of which, in all of its significance, is from the back porch of the Presi-

dent's house, the grounds of the mansion extending unbroken to the river's brink; everywhere else are blocks of houses, and paved and drained streets, each modifying this influence for its neighbor. Stroll through the president's grounds to the river and you can see and smell huge sewers emptying their contents upon the surface of these flats, there is no current and no channel except off in the distance.

Here is where Congress has been asked year after year to reclaim valuable land, build a river wall, direct the course of the channel, and give Washington a healthy river front, and from the condition here existing comes the assertion from all sections of this country and from Europe, that Washington is unhealthy. It was the hope that this extended and growing feeling and expression of public opinion would induce Congress to take some such action which has kept the local medical men so long quiet, until now this expression has grown to be seriously objectionable. A District physician cannot visit a neighboring city or watering place without meeting strong assertions of the unhealthiness of Washington, which no arguments of his can controvert.

It was time then that the public should have a fair and full statement of facts, and health officer Townshend, in his annual report, which virtually closes with June 30, 1881, adds a supplement, giving a comparative statement, which shows the deaths from the principal zymotic diseases in fourteen of our largest cities for the thirteen weeks ending September 7, 1881, in which statement Washington stands as the fifth highest, coming after Pittsburgh, New York, Brooklyn, and Baltimore. He further states that the showing as to healthfulness is better this year than last.

The result of the issuing of the circular by the medical society, was such as to warrant the preparation of a statement, which was given to the public press, and which showed that Washington had greatly improved in its general sanitary condition during the last ten or fifteen years; that during that time there has been a gradual but decided diminution in extent and intensity of diseases of a malarial nature, which is due to improved drainage, better paved streets, and the filling in of low lands; that deaths from uncomplicated malarial diseases are rare, and that in taking the death-rate for comparison it must be remembered that one third of the population is colored, in whom the death-rate is almost double that of the white race. It further refers to the general good health of former occupants of the president's house, all of whom, down to the time of Buchanan's administration, resided there during the summer and fall months.

Some sixty or more physicians responded to these circulars, they represented almost all of the medical men engaged in active practice in the district, and they gave in detail what has been embodied in the above paragraphs.

—The alarm in regard to cholera in Egypt has largely subsided, and it is thought that travelers may safely leave out of their calculations the possibilities of an epidemic.

A STEP IN THE RIGHT DIRECTION.

THE action taken by the meeting of the censors from the several district medical societies throughout the State, held in this city on Thursday last, seems to offer hope that a much-needed reform in the methods of admission to membership in the Massachusetts Medical Society may be about to be effected. This meeting, the proceedings of which appear on another page, was called at the suggestion of the Councilors, this suggestion being in its turn the result of a petition to that body by the Suffolk District Board of Censors praying the council to take some action to secure a uniform standard of examination. The idea of an annual meeting is a good one, and we trust it will be made a permanent institution by the necessary addition to the By-Laws of the Society; the revision of the By-Law governing the qualification of membership is also important, for the censors cannot be expected to enforce a By-Law which has ceased to be an entity and allows such a great diversity of interpretation as does the one in question.

Should a comparatively uniform and reasonably severe examination be insisted on throughout the State the Massachusetts Medical Society would gain much in prestige, and a certificate of fellowship would soon come to mean much more to the laity than at present, inasmuch as it would guarantee at least respectable attainments, and would lift the Society above the plane of the many other irregular medical societies with whom we are now so ignominiously lumped in the Boston Directory.

ANOTHER ASYLUM CONFLAGRATION.

OUR readers will remember that in March last we had occasion to call their attention to the subject of fire in insane hospitals. We regret that the time has so soon arrived for chronicling another large fire.

This time the State Institution for Idiotic and Imbecile Youths of Ohio, which is near the city of Columbus, has fallen a prey to the flames. The fire fortunately broke out in the morning, when the six hundred and odd pupils were in school, and hence by good discipline they could be marched out without loss of life.

In spite of various appropriations which had been made to provide the asylum with fire extinguishers and other means of protection, "the hose and fire apparatus of the institution for such an emergency proved to be totally worthless."¹ One great source of failure was the scarcity of water. We learn that the State has refused to appropriate money to extend the city water-mains, and the asylum has been furnished with water pumped up from the river. As is often the case, a water-tower capable of throwing fifteen hundred barrels of water on to the building *would have been* finished in a few days.

The loss to the State will be upward of \$200,000, but much more will be required to rebuild the institution.

On the other side of the road from the asylum

¹ Cincinnati Commercial.

stands the Central Asylum for the Insane, containing one thousand inmates, and relying for its water supply on the same pumping arrangements.

As the State of Ohio has already lost a State House, the old Central Insane Asylum, the Cleveland Asylum, and other structures, and as these institutions have not been insured, she may eventually be expected to erect fire-proof buildings.

The Ohio people have cause to be grateful that the idiot asylum was not burned in the dead of night, as the loss of life might have been terrible. And once more institution managers have had a warning that until they have provided thorough and practical measures of protection against fire they have not done their whole duty to those under their charge. Massachusetts has, so far, been fortunate, but her turn may come next.

MEDICAL NOTES.

—The enthusiastic nomination of Dr. Samuel A. Green, the City Physician, for Mayor of Boston, by both the Republican and Citizen's conventions, is an honorable and flattering tribute to the personal character and judgment of a member of the profession, who is probably as widely known and as kindly regarded as any in the city.

—The somewhat sudden death of Dr. John Bacon, formerly professor of chemistry at the Harvard Medical School, occurred at his home in this city November 28th. He was a graduate of Harvard College and of the Medical School, at which he was appointed professor of chemistry in 1857. Dr. Bacon discharged the duties of this professorship until 1871, when he resigned on account of ill health.

—The American Public Health Association met at Savannah, Ga., last Tuesday, November 29th. Next week we hope to give our readers an account of its proceedings.

—The returns for last year from India state that the number of persons killed in that country by snakes and wild beasts has increased from 19,273 in 1876 to 21,900 in 1880. In Bengal alone 10,064 persons are reported to have died from snake-bites, and 359 were killed by tigers. The trustworthiness of the returns is questioned, and it is thought that many of the reported deaths by snake-bites were really cases of suicide, the former cause of death being given by the family and accepted by the police.

—The streak of silver sea around the Isle of Man has had, says the *Medical Times and Gazette*, a very distinct influence on the character of the mental diseases which prevail there. A pent-up population has intermarried to an extraordinary degree, and the result is that congenital mental defects abound there to an extent unknown in any other part of the kingdom.

Of the patients admitted into the Isle of Man Asylum, 10.9 per cent. labor under congenital impairment of intellect, whereas, of all patients admitted into asylums in England and Wales, only 4.1 per cent. are thus afflicted. Hereditary predisposition can be clearly traced in 34 per cent. of the lunatics in the

Isle of Man, but only in 18 per cent. of those in England and Wales. On the other hand, the moral causes of insanity, including domestic sorrow, anxiety, business trouble, religious excitement, fright, and nervous shock, are much more powerfully operative in England and Wales than in their adjacent island. Contrary to what might have been anticipated, intemperance causes a less proportion of insanity in the Isle of Man, which was long so celebrated for its smuggling and illicit stills, than in England and Wales. The Isle of Man Asylum, which is under the superintendence of Dr. Otterson Wood, contains now about 150 patients.

—A medical officer of Health calls attention in the *Lancet* to a possible source of lead-poisoning. "In decanting a bottle of good port wine a few days ago," he writes, "I noticed a somewhat more tawny color of the wine than its age would justify. The wine had no bad flavor, but on examining the bottle more carefully two large shots were detected in the bottom, and readily removed. Had there been any 'crust' upon the bottle this might not have been so easily done. The wine contained an appreciable quantity of lead, but no arsenic. The shots no doubt got lodged in the bottle during the familiar process of washing out crusted wine bottles. Here we have another possible (and to me new) means of lead-poisoning.

"In some experiments made thirty years ago I found that two dozen common shots placed in a quart bottle of spring water for a month, at ordinary temperature, only very slightly contaminated the water with lead, nor was there any reaction with the usual tests for arsenic. The shots, in spite of many industrious shakings up of the bottle, soon became encrusted with a deposit from the water, which was of medium hardness."

Miscellany.

THE PROBABLE CAUSE OF THE IMPURE WATER IN BOSTON.

SPONGILLA FLUVIATILIS.

For about eight weeks the water in certain parts of the city has had a disgusting taste and smell, not unlike fish oil. The water commissioners asked Prof. Ira Remsen, professor of chemistry in the Johns Hopkins University, Baltimore, to investigate the matter. He did this in a careful and systematic way, and has made an excellent report. He soon found that the water in Farm Pond contained a large quantity of "albuminoid ammonia," or that "produced by the oxidation of nitrogenous organic substances," but for some time there was no clue as to where it came from.

On November 16th Professor Remsen happily found caught on the screen at the effluent gate of Farm Pond moss-like matter which had the same peculiar nauseous smell as the water in Boston.

On account of this similarity of smell, he thinks it is more than probable that this substance is the principal cause of the trouble.

This bad smelling matter was recognized by Professor Farlow of Harvard University, and by Professor Hyatt, curator of the Boston Society of Natural History, as belonging to a fresh water sponge.

Professor Hyatt, who is an authority in these matters, says, that this animal is the *spongilla fluviatilis* of authors. He says there are many things about it that are unknown. For a long time it was thought to be a plant. It is not certain if it is or is not the same as either of the two similar varieties found in Europe, nor even if these two varieties are distinct ones themselves. Mr. George Dawson of Montreal has divided the fresh water sponges into quite a number of species, but they are difficult to identify on account of their minute differences. There has not been sufficient time to ascertain the exact name of the Farm Pond specimens.

This sponge is generally arborescent in shape, sometimes massive, commonly under a foot in length, though sometimes reaching to eighteen inches. Professor Hyatt has never seen one over twenty inches long.

The skeleton which supports the animal is made of a net of siliceous spicules. These project on all sides, and being covered by the animal substance, give a spiny appearance to the sponge when partially dried. These are the moss animals, so called on account of their small bush-like and creeping growths, which are found attached to solid objects lying on the bottom, or floating in the water.

Probably on account of these spicules of flinty matter no animal is known to feed on spicular sponges, except a mollusc, the body of which is found filled with the spines. They probably pass through his tissues without injuring him, as a needle may through the human flesh.

While alive the sponge is of a greenish color, due probably, as in plants, to the effect of light, as the parts of similar animals which remain under stones in the dark are of a light brownish hue.

This sponge lives in fresh-water ponds, nor can *clean* ponds be said to be free from it, and one of the first things to do should be to ascertain the truth about this, if it is not too late to do it this year.

We might expect it to prosper in ponds with dirty bottoms, and occasionally, as in Farm Pond, to multiply excessively, die, decay, and impregnate the water with the stench of decaying animal matter. A pond with a clean bottom, though not completely free from it does not probably offer the conditions necessary for its excessive growth.

This sponge does not probably live in the water pipes. The current and the pressure of the water would probably interfere with its growth. What has been found on the interior of water conduits, and has been mistaken for the seed bodies of the sponge, are probably the seed bodies of some kind of bryozoa. Alive it is quite smooth externally.

In our water supply this sponge has not yet been found out of Farm Pond, but it has not been carefully looked for anywhere. It is not impossible that it exists in the Sudbury River Basin No. 2, where Professor Roman finds more than a due allowance of nitrogenous matter; as with other growth, there are a few ponds where they can always be found.

The city government having refused to grant the sum necessary to remove the dam when the Sudbury River basins were made, though urged by the city engineers, the field was simply overflowed by damming up the river, and whatever remained of manure or dead leaves or dirt of many years was left at the bottom of the basins which were to supply the city of Boston with water, with the hope that they would clear themselves in time.

Let us hope that Basin No. 4 and the others that are to be made will not be built in this way.

Farm Pond is a shallow collection of water in a natural basin, and contains everything that for centuries has been washed down the sides into it. In some parts the mud is quite deep. It has no current of its own, but when the Sudbury River is high it is filled by it, and in dry weather the pond drained into the river through the same opening. The dam put up at this outlet keeps the water at a uniform level, and makes it about one foot and one half to two feet higher than it would otherwise be.

It is not impossible that even before, or shortly after, finishing the way by which the water from the basins will no longer pass through Farm Pond, the evil may come to an end of itself, as it did in Baltimore. Probably because there was no more animal matter left to decay, and nothing but spiculae and seed bodies remain. These are what are known as winter buds, by which the animal is propagated. Little is known of them. Many remain in the spicular skeleton, after the decay of the animal, and some are probably carried off by the water. They lie dormant during the winter and then produce moving creatures which after a while fix on some solid body and grow into sponges.

Whether they produce increased crops at irregular intervals of time, what influence the character of the mud, or the effect of a steady current, has on their growth, or whether they could be killed by intense cold, such as the ice which covers the pond protects them from, or whether desiccation kills them, and many other points, are still to be found out.

There is a *spongilla* in India which infests the water tanks and which after being dried up comes to life again after immersion into water.

It is probable that if Farm Pond could be drained completely, and its bottom exposed to a cold several degrees below zero, which we shall certainly have some time this winter, all the seed bodies of *spongilla* would be killed.

Whether this can be thoroughly done, and the effect it would have on the other organic growths in the pond remains to be seen.¹

It is possible that if Farm Pond was thoroughly drained and its bottom exposed to a cold of several degrees below zero, which we shall probably have some time this winter, the seed bodies might be killed. As this is by far the greatest evil we have suffered from it might be well to risk making the water unpalatable in some other way by so doing.

The subject is so important that probably the proper authorities will appoint some competent person or persons to investigate it in a thoroughly scientific manner.

It will be interesting, now that the principal cause of the present nuisance has been probably found out, to see how often it has been suspected before. It is not the first time that spiculae of sponge have been found in ponds of bad water.

The accompanying illustration, from Johnston, is the *spongilla fluviatilis* of Europe, which, if not identical with the Farm Pond one, is so like it that the same picture will do for both. Johnston says:—

"When allowed to putrefy in water, a thick fatty

¹ About twenty years ago Mr. Bowerbank, an English author on sponges, wrote to Mr. Theodore Lyman, of this city, asking for information about a *spongilla*, which he had been informed had appeared in the Cochituate water.

layer covers the surface of the fluid, the water acquires a turbid yellowish color, the spongilla becomes of a blackish green hue, and emits a most offensive putrid animal odor, like that of the most putrid offals."¹

Marine sponges have also a peculiar and disagreeable odor, when first exposed to the air, produced by the decay of the animal substance in them. Corals likewise have the same odor.

Figure 1 represents the sponge growing from a branch. Figure 2, the seed bodies held in the spicular skeleton. Figure 3, a part of the same enlarged. Figure 4, a seed body enlarged. Figure 5, isolated spiculæ enlarged.

LETTER FROM PHILADELPHIA.

MR. EDITOR, — Your correspondent having been invited to witness a recent ovariectomy operation by Dr. Atlee, it occurred to him that the details of the case might prove of some interest to the readers of the Boston Medical and Surgical Journal.

Dr. Walter F. Atlee, the nephew of the late Washington L. Atlee, the pioneer of ovariectomy in this city, is the son of Dr. John L. Atlee, of Lancaster, himself a distinguished operator, who with advancing age seems to grow only more active and enthusiastic in his profession; though delicate in frame he still has enough energy to put to shame many of the present genera-

tion; he has performed the operation over sixty times; the son, also, has operated frequently, though, unfortunately, he has not a complete list of his cases, but they cannot be less than fifty. Dr. Atlee, *filis*, states that he has saved fully ninety per cent., although some were complicated; in one case finding also a fibroid of the uterus he removed both ovary and body of the uterus, with complete success. In another case a supposed ovarian tumor turned out to be an extra-uterine pregnancy; the child was dead when removed (it is now in the museum of the College of Physicians); the mother entirely recovered. In view of Dr. Atlee's experience and success the details of his method and a report of a case will merit some attention.

Before performing the operation some preparation is required. In order to avoid any delay or misunderstanding it is the habit of the surgeon to give written directions to the patient to have ready: —

"Two basins, a bucket, a tin cup, a small tub, a pitcher of hot water, towels, cotton or carbolized tow, one and one half yards of flannel, large pins, a package of patent lint, ice, brandy, a feeding cup (or a glass tube bent), one ounce of chloroform, eight ounces of ether, bottles of hot water, adhesive plaster, a patent ironing-table.

"The patient must have on a night-dress and warm woolen stockings. The day before the operation a dose of castor oil is to be given, and nothing to eat afterward only barley-water. On the morning of the operation an enema of warm water is given."

In performing the operation, the patient, having her night-dress drawn up above her waist, her feet protected by woolen stockings, and her lower limbs covered with a double blanket, is placed upon a patent ironing-table, which allows the greatest liberty to the surgeon and his assistants; the table is just large enough for the patient to lie upon, and it is covered by a quilt or blankets to make the woman comfortable. The patient has her knees and elbows secured by a roller bandage so as to prevent struggling and falling from the board during the administration of the anæsthetic. A rubber blanket is then thrown over the patient, in which there is a large central opening, which corresponds with the anterior surface of the abdomen, the edges of this opening are secured to the abdominal wall at the circumference by soap plaster. The patient has not been allowed any food except barley-water since the preceding day, so that there is very little if any vomiting. Ether and chloroform, but principally the former, are used. The patient being ready, an incision in the median line, passing between the recti muscles, is made down to the peritoneum. All bleeding having been stopped by torsion, *serres-fines*, or ligature, the peritoneum is now cut into, the entire incision being from four to five inches in length, extending rather nearer to the pubes than to the umbilicus. A large trocar is used to evacuate the cyst if it exist, and the contents flow through India-rubber tubing into the tub underneath the table. When all the cysts are broken up, and their contents evacuated, taking care that the fluid does not pass into the peritoneal cavity, the sac is brought outside, the adhesions, if any are found, torn, and the ordinary Atlee clamp is applied to the pedicle, which is allowed to project from the wound. No carbolic spray is employed, the only use made of carbolic acid is to cauterize the raw surface of the pedicle after its section, as it appears in the clamp; otherwise the dead, sloughing tissue gives rise to very

¹ Johnston, British Sponges, and Lithophyles. Edinburgh, 1842, age 161.

had odor in the sick-room in the course of a few days. The "toilet of the peritonæum" is made with the greatest care; all blood and discharge from the tumor is carefully sponged out, the sponges being washed in carbolized water. The abdominal wound is brought together by four or five points of interrupted suture, using waxed silk ligatures armed with two needles, each point being passed in a direction from the inside including the peritonæum, the edges being neatly approximated. The dressing is completed by placing a quantity of carded cotton over the abdomen and under the ends of the clamp; it is all held in place by a flannel bandage. No morphia nor quinia is employed prior to the operation, but a tablespoonful of brandy is administered just before the anæsthetic is given, and some hours after, if there is pain or restlessness, a pill containing one eighth of a grain of valerianate of morphia is used, which may be repeated once or twice on the following day. The patient is kept quiet, and, if possible, in charge of a trained nurse.

The following are the notes of the case:—

Alice D., thirty-nine years of age, never married, had always menstruated regularly until the last six months, when she menstruated twice a month. About January, 1871, she had noticed a throbbing and fullness in the left side and lower part of the abdomen, subsequently the abdomen gradually enlarged. In 1878 she also had swelling of the feet.

When Dr. Atlee was first consulted in August, 1881, she measured over fifty inches in girth, and the lower limbs were much swollen. A tumor of the left ovary was diagnosed, and it was thought to be unilocular. She was then tapped, and three gallons of dark-colored, opaque fluid were obtained, two cysts being opened that were contained in the larger one. [This fluid examined microscopically by the reporter was found to contain the large glandular cell and an abundance of cholesterine. F. W.]

On November 17th the tumor had refilled, the abdomen measuring fifty-one inches; the operation, for which permission had been previously refused, was performed at eleven o'clock A.M. in the presence of Dr. John L. Atlee of Lancaster, Dr. Can of York, Drs. Harris, Carroll, and Woodbury of Philadelphia. The operator was assisted by Dr. Washington T. Baker and his son Mr. Lewis W. Atlee, and by his father, already named. The steps of the operation were carried out as above described; there were a number of adhesions, but no peritoneal hemorrhage. More than three gallons of fluid were obtained, similar to the first in appearance and consistency; it very much resembled crude coal oil.

The patient bore the operation (which was entirely completed in half an hour) very well; there was no vomiting; the pulse was better after the operation than before. The same evening one pill of valerianate of morphia was given, and the following day two pills. On Sunday, November 20th, it is noted that the monthly sickness came on this morning (she had last menstruated about two weeks prior to the operation). Has had no food since the operation except milk and beef tea¹ in moderate quantity, about a pint of each daily. The urine was still drawn by the catheter. Bowels not moved, although there was a discharge of

flatus (favorable sign). She had taken only four of the morphia pills since the operation. Pulse 104, temperature not taken, but there had been no marked febrile movement. The amount of milk was now increased, so that she took four pints during the following twenty-four hours. November 21st the dressings were removed for the first time, and the wound looked healthy. There seems to be every reason for hoping for a speedy convalescence.

Dr. John Atlee, in Lancaster, performed ovariectomy on the succeeding day (November 18th); the following are the details of the case, kindly communicated by him in a private letter. The character of the tumor in this case is different from the preceding.

"Miss Grace K., aged nineteen, of rather delicate frame, came to me September 6th with her mother. For two years she had been subject to a gradual enlargement of the abdomen, which had increased so much as to occasion difficulty of breathing in the recumbent position, great œdema of the lower extremities, and partial suspension of the menses, which had first commenced at the age of fifteen. Her appetite was good, the bowels regular. Upon examination I found the fluid ascitic, and in the general cavity of the peritonæum. By strong palpation I could strike through the fluid upon a very hard tumor in the hypogastric and iliac region, more especially the right side. Examination per vaginam discovered the brim of the pelvis filled with a very hard tumor pressing upon the iliac vessels and causing the œdema. The uterus was in normal position, although not very movable, and the sound passed the normal distance. The next day I took away two and a half gallons of ascitic fluid, very greatly to her relief. I then found a very hard fibroid mass, as above stated, very movable, and causing the sound to move from side to side as if the tumor were connected with the uterus. I diagnosed an extra-uterine fibroid, or a fibroid of the ovary. I told her parents that if she filled again I would tap her again, and then make an exploratory opening into the abdominal cavity, and if I found it practicable I would remove the tumor. She went home, and enjoyed great relief and excellent general health until recently. When the gradual filling up took place, and she was brought here on the 16th, I found her not so large as before, but that the size of the tumor had very sensibly increased, extending now above the umbilicus and occupying the whole lower portion of the abdomen.

"I commenced the operation this morning after eleven o'clock, in the presence of Drs. Atlee, Jr., H. E. Muhlenberg, Roland, Westhoeffler, Welchens, and Hunt of Portland, Me. The first incision was about four inches long, and when I got down to the peritonæum I found it exceedingly vascular and very much thickened. I then introduced the trocar and took off about one and a half gallons of straw-colored serum. Upon slitting open the peritonæum a hard, solid tumor was exposed, covered by a thick membrane resembling the albuginous coat of the ovary. I passed my finger around it and found it to be a solid fibrous mass containing no fluid, and dipping down from above the umbilicus to the very bottom of the pelvis. There were a few slight adhesions, which I tore with my fingers. I then enlarged the wound to near the umbilicus, and by careful manipulation and strong traction with the bulldog forceps of Pean, I brought the whole mass out, and to my infinite satisfaction I found it was the enlarged left ovary, with a good, long, and not very thick

¹ Dr. Atlee prefers the beef tea to beef essence, he orders it made with a pint of lean beef steak cut up small and soaked in cold water, the gravy being left to a boil and allowed to boil fifteen minutes, then skimming, strained, and seasoned.

pedicle. I applied the clamp, cleansed the abdomen of all fluid, and closed the wound. I used ether and chloroform combined for the anæsthetic (ether three fourths, chloroform one fourth).

"She bore the operation well. Four hours afterwards I found there had been little or no shock, hands and feet warm, patient lively, and only complaining of a burning in the track of the wound. I think she will make a good recovery. There was no carbolic acid used except a little in the water in which the sponges were washed, and a strong solution to the pedicle outside of the clamp."

WALSH'S RETROSPECT ON PRESIDENT GARFIELD'S CASE.

THE October issue of *Walsh's Retrospect*, a quarterly, devotes the editorial department to a consideration of President Garfield's wound and its treatment. Letters are given from the surgeons who were present during the first stages after the shooting, containing short statements of what then took place, and these are compared with the statements of Dr. Bliss, published in the *New York Medical Record*. From the editor's comments upon the material presented the following extracts are taken:—

What opinion must one form of a paper so at variance with the statements of reliable gentlemen?

We approach a criticism of the treatment with no pleasure. We would gladly say we believe it to have been correct in each detail, but we are compelled to assert that in our opinion the failure to enlarge the wound and remove the spicula of bone soon after reaction was established was a great mistake, possibly a fatal mistake. In substantiation of this assertion we quote from Dr. Hamilton's work on *Military Surgery*, page 265. In speaking of gun-shot wounds involving the ribs, he says:—

"An examination ought always to be made with the finger or probe to determine whether a rib is broken, and at the point of entrance a reasonable effort should be made to remove such loose fragments as may happen to be within reach. One of the most frequent causes of death and of delay in recovery is found to be *small spicula of bone loosened or completely detached from the rib.*"

We believe if an early enlargement of the wound had been made and the spicula of bone removed, in other words, if the incisions necessary to liberate pus and remove spicula of bone had been made before the mischief was done, instead of after, the pus cavity would not have formed.

And is it unreasonable to suppose that if an early enlargement of the wound had been made, the spicula of bone removed, and *free drainage from the right side of the vertebra obtained*, enlarged facilities for digital exploration would have been gained, the pus cavities and false channel not have formed, the false diagnosis not have been made, and the danger of pyæmia greatly lessened?

It is useless to attempt to gloss the mistake of not finding the wound in the right side of the vertebra by inferring what a rash surgeon might do after he found it, or to attempt to bury the mistake in a host of anatomical and surgical difficulties surrounding the extraction of the ball when there existed no reason for its extraction.

Our second assertion is that with thorough cleansing and drainage from the right side of the vertebra the wound of the vertebra was not necessarily fatal. For a wound to be necessarily fatal there must be no exceptions to death from such injury.

Our third assertion is that a traumatic aneurism was not proven by the autopsy. . . .

Briefly summarizing, we say that the failure to enlarge the wound and remove the spicula, the treatment of a false sinus for the track of the ball, the issuing of bulletins creating public distrust, the performance of the autopsy without the presence of eminent, disinterested pathologists, the arrival at uncertain deductions from said autopsy, and the false "report" made, have done more to cast distrust upon American surgery than any case heretofore known to our medical history.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM NOVEMBER 19, 1881, TO NOVEMBER 25, 1881.

McKEE, J. C., major and surgeon. The extension of his leave of absence on surgeon's certificate of disability granted him in S. O. 189, August 18, 1881, from A. G. O., is further extended six months on surgeon's certificate of disability. S. O. 262, A. G. O., November 19, 1881.

PAULDING, H. O., captain and assistant surgeon. Having reported at these headquarters per S. O. 249, C. S., A. G. O., will report in person to the commanding officer, Fort Laramie, W. T., for duty. S. O. 118, Department of the Platte, Nov. 19, 1881.

CARTER, EDWARD C., first lieutenant and assistant surgeon. To report in person to the commanding general, Military Division of the Pacific and Department of California, for assignment to duty in Department of California. S. O. 263, A. G. O., November 21, 1881.

RAYMOND, H. I., first lieutenant and assistant surgeon. To report in person to the commanding general, Military Division of the Pacific and Department of California, for assignment to duty in Department of California. S. O. 263, C. S., A. G. O.

COTES, ELLIOTT, captain and assistant surgeon. His resignation accepted by the President, to take effect this date. S. O. 260, A. G. O., November 17, 1881.

SUFFOLK DISTRICT MEDICAL SOCIETY. — The Section of Clinical Medicine and Pathology will meet at No. 19 Boylston Place, on Saturday, December 3, 1881, at eight o'clock. Paper, Dr. H. I. Bowditch, A Fatal Case of Acute Pleurisy which occurred in 1873 in one of the Great Cities of Europe, with Remarks thereupon and Criticisms of the Treatment. Drs. F. Minor, G. G. Fairbell, H. Osgood, A. T. Cabot and others are expected to take part in the discussion.

ALBERT N. BLODGETT, *Secretary*.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held on Monday evening, December 5th, at eight o'clock, in the hall of the Medical Library Association, 19 Boylston Place. Reader, Dr. S. W. Langmaid. Subject, Tracheal Tumors resulting from Tracheotomy.

M. H. RICHARDSON, M. D., *Secretary*.

Deaths reported 2662 (no report from New Orleans): 964 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 754, consumption 492, lung diseases 298, diphtheria and croup 273, typhoid fever 125, diarrhoeal diseases 105, small-pox 74, scarlet fever 67, malarial fevers 54, whooping-cough 18, cerebrospinal meningitis 15, measles nine, erysipelas eight, puerperal fever four, typhus fever two. From small-pox, Pittsburgh 22, Chicago 20, Philadelphia 18, New York seven, Cincinnati three, Brooklyn two, Buffalo and Holyoke one. From scarlet fever, New York 30, Brooklyn 15, Pittsburgh five, Buffalo four, Philadelphia three, Chelsea two, Chicago, Baltimore, Cincinnati, District of Columbia, Milwaukee, New Haven, Worcester, and Beverly one. From malarial fevers, New York 16, Brooklyn 11, St. Louis, nine, Philadelphia four, Baltimore, District of Columbia, and Buffalo three, Chicago two, Charleston, Nashville, and Holyoke one. From whooping-cough, New York nine, Chicago and Boston two, Philadelphia, Brooklyn, Buffalo, Providence, and Taunton one. From diphtheria and croup, New York six, Chicago three, Philadelphia, Brooklyn, St. Louis, Cincinnati, Milwaukee, and Worcester one. From measles, New York four, Buffalo three, Chicago two. From erysipelas, New York two, Philadelphia, Brooklyn, Baltimore, Cincinnati, Buffalo, and Milwaukee one. From typhoid fever, New York, Philadelphia, District of Columbia, and Providence one. From typhus fever, Philadelphia and Chicago one.

There were no cases of small-pox were reported in Brooklyn, one in Boston, four in St. Louis, six in Baltimore, nine in Cincinnati,

and 73 in Pittsburgh; diphtheria 27, typhoid fever 16, scarlet fever six, in Boston; diphtheria 16, scarlet fever 13, in Milwaukee.

In 40 cities and towns of Massachusetts, with a population of 1,072,329 (population of the State 1,783,086), the total death-rate for the week was 18.48 against 18.72 and 20.16 for the previous two weeks.

For the week ending October 29th in 149 German cities and towns, with an estimated population of 7,924,809, the death-rate was 22.3. Deaths reported 3405; under five 1549; pulmonary consumption 449, acute diseases of the respiratory organs 263, diphtheria and croup 195, diarrhoeal diseases 134, scarlet fever 122, typhoid fever 72, whooping-cough 66, puerperal fever 22, measles and Ætheln 20, small-pox (Breslau) one, typhus fever (Thorn) one. The death-rates ranged from 10.4 in Frankfurt A. M., to 39.3 in Essen; Königsberg 30.6; Breslau 27.3; Munich 29.8; Dresden 20.5; Berlin 21.9; Leipzig 21.6; Hamburg 21.2; Hanover 15.7; Bremen 18.2; Cologne 24.4; Strasburg 27.6.

For the week ending November 5th in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 22.8. Deaths reported 3317; acute diseases of the respiratory organs (London) 375, scarlet fever 187, fever 100, whooping-cough 82, measles 79, diarrhoea 47, diphtheria 28, small-pox (London) 12) 14. The death-rates ranged from 17.2 in Wolverhampton to 28.4 in Liverpool; Bristol 18.6; Leeds 18.8; Sheffield 21.6; London 22.4; Manchester 22.9; Birmingham 24.9. In Edinburgh 18.7; Glasgow 24.9; Dublin 30.5.

A CASE OF MORBUS MACULOSUS WERLHOFFII.
(PURPURA HÆMORRHAGICA. PSEUDO-
RHEUMATISM).¹

BY W. E. BOARDMAN, M. D.

On April 17th I was requested to visit Mr. C., of this city. A stranger to me, he showed himself to be a man of considerable intelligence, of excellent physique, well formed, of medium height, good weight, and nervous temperament. Upon inquiry I learned that he had always enjoyed excellent health, had been accustomed to observe unusual regularity in all his habits of life, and had never been addicted to the use of stimulants or tobacco in any form. His occupation was such that he spent most of the daytime in the open air and required considerable active exercise. He was nicely housed, and in comfortable circumstances in all respects. So far as could be ascertained at the time there appeared to be no hereditary, congenital, or acquired disposition to disease in any form.

He had experienced his usual excellent health until a few days or a week prior to the date upon which I was consulted for the first time. During that interval he had complained of some languor and inability to attend properly to his customary routine duties. Without experiencing any chill or even any sensation of chilliness, observing no symptoms of fever, he soon noticed pain in his ankles, followed in a day or two by tenderness and swelling of these joints. Subsequently both knee joints became similarly affected. When he first came under my observation, he was in bed, pulse 100, temperature 100.6° F., respiration normal. General appearance somewhat pale and careworn, considered to be due, in a great measure, to loss of sleep and anxiety on account of the interruption of his business, in addition to the pain from which he had suffered. There had been sleeplessness, loss of appetite, and general deterioration of strength, but the ordinary functions appeared to have been well performed. The before-mentioned joints were painful on pressure, somewhat swollen, and slightly reddened. The surface of the body generally was warm, but not moist. The lower extremities, below the knees, were cooler to the touch than the rest of the body. Examination of the thoracic and abdominal organs showed nothing abnormal. No analysis of the urine was made at the time, but inquiry elicited nothing unusual concerning it. The diagnosis of rheumatism, probably subacute, was readily made. I recommended that the affected joints should be enveloped with cotton batting, and prescribed salicylic acid in the usual way. On the following day I learned that my directions had been carefully observed, that the ordinary effects of the acid had been experienced during the night, that the pains had been relieved considerably, and that he had had some sleep; pulse 98, temperature 98.6° F., respiration easy and regular, heart sounds normal. I advised a continuance of the acid for a day or two, five grains every six hours, and also of the cotton wool dressings, to be replaced subsequently by flannel, and also a resumption of ordinary diet.

April 21st, three days later, I was requested to visit the patient again, when I learned that, during the preceding night, there had occurred what he considered

to be a return of the symptoms which had existed at my first visit. I found the joints presenting about the same appearance as before, and the temperature had again increased to 100.1° F. The acid had been stopped the preceding morning. I advised its resumption, and gave general directions similar to those given at my first visit.

I heard nothing more from my patient until May 2d, eleven days later, when I was summoned to him in great haste to relieve a very profuse and obstinate epistaxis, which already had continued several hours, and had become more violent in spite of the vigorous use of ordinary household remedies. Upon my arrival, the blood was flowing freely from both nostrils and the mouth. The patient's face was blanched, the general surface, as seen at a hasty glance, was pale. Both lower extremities, below the knees, were enlarged, apparently œdematous. The wrists and hands were in a similar condition. These parts, especially the lower extremities, were thickly studded with purpuric spots, some of them the size of a bean, or a little larger. The pulse was rapid and weak, but its exact frequency was not determined. I resorted to compression of the facial artery and to the use of various styptics, and finally succeeded in controlling the hæmorrhage by cotton wool tampons soaked in a solution of subsulphate of iron. In the mean time I was informed that since my previous visit the condition of the patient had improved somewhat, that is, the pains had subsided and his strength had returned to some extent. He had been able to sleep tolerably well, especially in the sitting posture. The swelling of the joints, however, had continued without perceptible change (they had not noticed the enlargement, apparently œdematous, of the lower limbs and hands), and having misunderstood my directions, he had continued to take the salicylic acid during the interval for the purpose of reducing the swellings. As near as I could estimate, he must have taken in all about three hundred grains.

No immediate cause could be assigned by the patient or his wife to explain the hæmorrhage. Upon inquiry I was unable to learn that any of his family were "bleeders," or that he had been liable to attacks of hæmorrhage of any kind. He had never had a tooth extracted, and the only fact of any importance in this direction which I did ascertain was that he never made use of a stiff tooth-brush, because it was liable to make his gums bleed a little. Before leaving him I examined him quite carefully. The pulse was rapid and weak, but regular. The respiration was a little hurried and somewhat labored. Nothing abnormal could be detected in the thoracic or abdominal cavities. The joints presented about the same appearance as at my first visit, the lower limbs pitted on pressure, as also did the hands, and the purpuric spots were present, as they have before been described.

I ordered tincture digitalis and ergot with perfect rest and simple, unstimulating diet.

On the following morning I was again summoned in haste, on account of a recurrence of the epistaxis. Upon my arrival I found the blood issuing copiously from the mouth, obviously from the posterior nares, and oozing from the gums, which, however, on being cleansed, displayed the clear, glistening membrane peculiar to the tissues of the oral cavity, without any appearance of sponginess or inflammation. The blood was also making its way outside the styptic tampons, which were removed and fresh ones substituted; but

¹ Read before the Boston Society for Medical Improvement, November 28, 1881.

these did not suffice to arrest the hemorrhage, and finally I was obliged to plug the nasal cavities, posteriorly and anteriorly. This procedure, together with styptic applications to the gums, checked the bleeding. During this visit I learned that in the night there had been a constant slight flow of bloody fluid into the mouth, that the patient had two evacuations of the bowels, consisting almost entirely of blood, some of it dark and some light red in color, and but little clotted, a feature which had been noticed with the preceding hemorrhages.

At this time the pulse, of course, was still rapid and weak, but not fluttering. There was considerable dyspnoea, but the respiratory sounds were clear and distinct. The heart's action was rapid and weak, but no other abnormal conditions could be detected. In the evening of this day, as on the following day, the patient's condition was fair. The oozing continued to some extent from the posterior nares, and he had other bloody stools. The urine examined on this day had a specific gravity 1016, presented a trace of albumen, and, under the microscope, numerous blood corpuscles, but no casts. The abdomen, too, presented a uniform enlargement, mostly resonant, or, rather, I was unable to detect any fluid, but for this purpose I was unwilling to change the position of the patient through fear of again starting hæmorrhage.

On the following morning his condition was about the same, though he thought he had a little more strength. His mind continued clear, as it had been throughout the illness. He complained only of fatigue, weakness, and the discomfort occasioned by the plugs. I still thought it prudent to allow these to remain, this caution being emphasized by the slight increase in the amount, and intensity of color, of the oozing blood.

At the morning visit of the next day I feared it would be necessary, before long, to repeat the process of plugging the nares, but concluded to postpone it, if possible, till the afternoon. At noon he suddenly became worse, with faintness, great dyspnoea, ending in collapse and death, after a brief interval, before a physician could reach him.

Upon my arrival I learned that the oozing had not increased much since the morning visit, nor had any new hæmorrhage been observed from other localities. Upon examination of the body externally, I found nothing additional to what has already been related, except that the abdominal enlargement seemed to be considerably greater, and percussion yielded a general dullness, but no wave could be determined. There was no autopsy.

Primary diagnosis, subacute rheumatism; final diagnosis, morbus maculosus Werlhofii, purpura hæmorrhagica, sometimes termed pseudo-rheumatism.

Cause of death, asthenia from external and internal hæmorrhage.

This case surely possesses the element of rarity, and therefore has some interest. I have presented it somewhat in detail with the view of eliciting discussion as to the correctness of my diagnosis, which has been questioned by some of my professional friends, and that I may, perhaps, receive suggestions as to treatment which might be valuable to me under similar circumstances, should they recur.

A brief recital of the more salient points connected with the disease, more familiarly known under the name purpura hæmorrhagica, will serve to confirm the correctness of my view of this case.

According to the most recent authorities, the term morbus maculosus is applied to a rare form of hæmorrhagic disease, which is characterized by the fact of its acquired, transitory nature and its apparently spontaneous development, its aetiology being still buried in obscurity. It is distinguished from the more common disposition to hæmorrhage, which is frequently observed as an accompaniment or a sequel of several acute and chronic diseases, and also from those affections in which the hæmorrhagic diathesis is hereditary. In the former cases the hæmorrhagic tendency is symptomatic merely, while the affection under consideration is regarded as an *essential disease*, which is developed suddenly in a previously healthy individual who possesses no hereditary disposition thereto. Some cases present a mild febrile stage, while others are unaccompanied by any febrile symptoms. Again, in some cases the fever is initiatory, while in others it occurs sooner or later after extravasation of blood takes place. Oftentimes the disease is ushered in by certain local disturbances, either with or without fever, which sometimes persist during the continuance of the hæmorrhages. The more common of these are pain and swelling, one or both, of the joints, usually of the lower extremities. These have been regarded by some as rheumatic in character, and hence the terms purpura rheumatica and peliosis rheumatica. The most recent authorities appear to agree that the articular affections in these cases are *consequent upon* the hæmorrhagic disease, a view which is not susceptible at present of absolute proof, though the probabilities in the matter undoubtedly confirm it.

The disease occurs at all ages in both sexes, and under every variety of constitutional condition, preferably, however, at or shortly after puberty and in females. Apart from the articular pain, to which reference has already been made, the hæmorrhages occur without pain or warning of any kind. The extravasations may take place over the entire surface of the body, and the viscera and cavities also may be the seat of hæmorrhage, though usually it is confined to the mucous cavities. The spots of discoloration vary in size and shape. Vesicles, too, sometimes are observed, but these are quite exceptional. The color of the spots is indicated sufficiently well by the common name of the disease.

Many cases end in recovery, the patient frequently manifesting no serious disturbance of the general health, while others present alarming symptoms of great pallor, extreme prostration, dropsical swellings, and fainting fits, and many terminate fatally after short or longer intervals.

Post-mortem examinations reveal practically nothing as to the cause of the malady, but merely its effects, nor have repeated examinations of the blood during life afforded any satisfactory conclusions. Recent authorities, however, appear to be in accord with the view that the affection has its origin in some primary disease, either of the blood or the vascular walls, or of both together.

This short summary of the chief points of interest which characterize the disease under consideration, I think, will enable us at once to eliminate, in a differential diagnosis, most of the affections which might be suggested by some as the essential disease. We may, therefore, exclude, without any discussion, diseases of the thoracic and abdominal viscera, leukaemia, progressive pernicious anaemia, typhus and typhoid fever, cere-

bro-spinal meningitis; embolism, for the history of the case furnishes nothing to indicate the existence of any of these affections.

In some instances it is not an easy matter to distinguish between hæmophilia and morbus maculosus. Our present case, however, does not present the hereditary element which is an essential of the former disease, nor did the patient furnish any evidence of an hereditary hæmorrhagic tendency. Nothing in his record would suggest this unless, possibly, the fact that his gums were apt to bleed slightly when he made use of a stiff tooth-brush, a not uncommon occurrence with many of us.

Under some exceptional circumstances it is difficult to distinguish between *scorvy* and morbus maculosus. Our patient, however, was in good circumstances, hygienic and otherwise; had been accustomed to the ordinary variety of diet; had been subject to no privation. No similar case occurred in the family or neighborhood. The disease evidently was "spontaneous" in its origin. There were no distinct prodromic symptoms, except a feeling of languor and inability to attend to his ordinary duties for a few days. Previous to that time he was in perfect health. The gums, from which the blood was seen to exude, presented a perfectly healthy appearance. As far as we were able to judge, none of the local symptoms afforded any evidence of an inflammatory process which is very common in scorvy.

The so-called rheumatic symptoms presented by our patient, that is, the swollen and painful joints, accompanied by a slight rise of the pulse and temperature, claim, perhaps, further consideration in making the diagnosis. It has already been stated that recent authorities are inclined to agree that mild, apparently rheumatic, symptoms occurring in association with phenomena which, without them, would indicate the existence of the purpuric disease, may, with good reason, be regarded as *symptomatic* merely. Reference to the recorded experience with acute rheumatism cannot but confirm this view. It has been shown that with the association of the symptoms the rheumatic elements never obtain any decided prominence; that they are not attended by notable perspiration and never are followed by the grave complications peculiar to the articular disease. In some undoubted cases of rheumatism extravasations of blood do occur, but it is known that this accident is due to embolic processes which have their origin in *endocarditis ulcerosa*, a condition of things which the clinical history of our patient could not suggest.

Admitting, however, with many, that it is impossible, with our present knowledge, to decide absolutely whether one or the other class of symptoms is symptomatic, it will be evident from the whole character of this paper that I rely upon the theory of probabilities in these cases in making my diagnosis, and so regard the hæmorrhagic affection as the essential disease.

It occurred to me, and has been suggested by others, that the condition presented by my patient may have been due to poisoning by salicylic acid, he having taken in all about three hundred grains. This supposition, however, may be dismissed with a few words. I know of no case on record where this agent is supposed to have given rise to symptoms resembling those presented by my patient. Excessive and long-continued doses, and smaller amounts in certain individuals, of this acid have been known to occasion a condition of extreme prostration, in some cases sudden and rapid collapse, together with cerebral symptoms varying from

those resembling cinchonism to acute delirium. Sometimes, too, it produces a miliary eruption which often becomes pustular in character. Urticaria, also, occasionally occurs as a complication. In no case, however, has the eruption become hæmorrhagic in character. Hæmorrhagic *erosions* of the stomach and intestines have been observed, but in these cases this accident has been considered to be due, probably, to adulteration with carbolic acid.

GROWTH OF BONE IN KNEE-JOINT DISEASE FROM MEASUREMENTS OF NINETY-TWO CASES.

BY J. J. BERRY, M. D.,

Late Intern of Hospital for Ruptured and Crippled, New York.

THE question which has been agitated during the past few years regarding the influence of disease of the joints upon the bones entering into their formation has resulted in the publication of very few cases illustrative of these changes. Jutland¹ has reported cases of elongation of the femur associated with disease of the hip-joint. Wagstaffe² publishes twenty-five cases, of which the femur was found to be lengthened in fourteen, and shortened in one case only. Helferich³ has given measurements of one hundred and forty-one subjects of caries of the long bones, but without special reference to disease of the knee-joint. In eighteen of these there existed an elongation of the femur in three cases only, while in fifteen some shortening was noticed.

The accompanying statistics were obtained from measurements of consecutive cases in children which came under my observation at the daily clinic during the past two years. The greatest degree of accuracy attainable was secured, and no reference is made to those cases in which there were well-defined evidences of disease, but in which no accurate notes were taken.

Of the cases under consideration sixty-eight were of articular osteitis, and gave the following results:—

In 2 cases	1 inch lengthening.
In 10 cases	1 inch lengthening.
In 19 cases	1 inch lengthening.
In 18 cases	1 inch lengthening.
In 8 cases	1 inch lengthening.

In six there was an average shortening of three eighths of an inch, while in five no change in length was appreciable. Owing to the difficulty of estimating so slight a variation as a quarter of an inch I would not claim for this measurement any great degree of reliability. In addition to this evidence of bony proliferation there was noticed in most of these cases a marked lateral expansion at the condylar extremity of the femur.

That variety of articular disease in which the morbid process was situated primarily within the synovial membrane, and may be included under the general term of synovitis, numbered twenty-four. In these there appeared to be little alteration as regards osseous development; in fact, there seemed to exist in some cases an arrest in growth rather than an intrinsic enlargement, as indicated by this table:—

In 5 cases	1 inch elongation.
In 3 cases	1 inch shortening.
In 2 cases	1 inch shortening.
In 14 cases	unaltered.

¹ British Medical Journal, February 5, 1881.

² St. Thomas's Hospital Reports, 1880.

³ Deutsch. Zeitsch. f. Chir., Bd. x., 1879.

I find among my notes eleven cases of osteitis of the tibia alone, which present the following alterations in size:—

In 5 cases	$\frac{1}{4}$ inch lengthening.
In 3 cases	$\frac{1}{2}$ inch lengthening.
In 3 cases	unaltered.

In the above I was unable to recognize any shortening of the tibia. All variations depend upon one of several distinct conditions. The duration of the disease before measurements are taken must be considered. There is absolutely no true bony proliferation after the epiphysis has become united to its shaft, and ordinarily very little during the first six months or after the second year; for the prolonged hyperemia attendant upon the necrotic process at or near the epiphysal junction advances too sluggishly and furnishes too few products of retrograde change to affect visibly the enveloping structure. It is not until the degenerative process, which we may now term miliary tuberculosis, has encroached upon the larger portion of the epiphysis and its cartilage, separated as it is by its calcareous lamina, and cell proliferation has proceeded unceasingly for many months, that bony deformity begins to manifest itself. I may state in this connection that a case of true osteitis which dates its inception subsequent to the twelfth year of life is of very rare occurrence.

The inconstant normal variation in the length of the femur should also be recognized; for it may serve to explain in a measure the elongation sometimes found in cases of synovitis when not accounted for by the deposition of layers of new bone about the periphery of the articular extremity.

As regards the location of the lesion, no case of femoral osteitis was examined in which the internal condyle was exempt from disease, though in many instances the whole lower third of this bone seemed to share in the inflammation.

The nature of the process is no longer obscure; for the researches of nearly all the modern investigators in this field of inquiry, as imperfectly indicated in a previous paper,¹ have illustrated quite satisfactorily its tubercular characteristics. They also appeared to have afforded additional weight to the theory that the effect of early synovial inflammation and also some forms of tuberculosis is not an atrophy or even sclerosis of the structure involved, but simply an arrest of development in one portion while the other centres of ossification perform their office uninterruptedly.

RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

BY WILLIAM F. WHITNEY, M. D.

CHRONIC INTERSTITIAL NEPHRITIS AND ITS RELATIONS.

THE occurrence of granular atrophy of the kidney, associated with hypertrophy of the heart, has been noticed since the time of Bright. Several hypotheses have been advanced as to the causal relation of the two. Bright himself explained it as a secondary phenomenon, resulting from the changed condition of the blood working on the heart. Traube also considered it as secondary, due, however, to an increase in the arterial

tension, following the obliteration of the vessels in the kidney, and consequent accumulation of water in the blood. Johnson, Sutton, and Gull have turned their attention to the changes in the arterioles of the entire body, and find in them a thickening of the walls and a reduction in the size of the opening. They are, therefore, led to consider the changes in the vessels as the primary lesion, to which the hypertrophy of the heart and the contraction of the kidney are associated later. Ewald confirms the fact that changes in the vessels occur, but, contrary to the above mentioned authors, considers the affection of the kidney as primary, which gives rise to changes in the blood, leading to increased tension in the capillaries of the entire body.

Still later authors, as Ziegler, recognize this arterial sclerosis as a frequent cause of the contracted kidney. Bartels denies this aetiology entirely, considering the interstitial nephritis as a disease *sui generis*, while Buhl sees in the fatty and fibroid degeneration of the arteries merely the result of the increased pressure from the hypertrophy of the heart, and not a cause of the interstitial nephritis.

The authors also differ among themselves as to the nature of this thickening of the coats of the vessels. According to Gull and Sutton there is found a layer of a peculiar hyaline, fibroid material upon the muscular coat, and they called this condition arterio-capillary sclerosis. The muscularis itself was unaltered, or else atrophied by pressure of the connective tissue. On the other hand, Johnson found a thickening of the middle coat of the smallest arteries. Dickinson, a thickening of the adventitia and muscularis. Ewald believes in the true hypertrophy of the muscular coat, but finds no abnormal relations in the adventitia or intima.

In order to reconcile these conflicting opinions, which are given more in detail in the original article, Sotnit-schewsky,² under the direction of Von Recklinghausen, examined the vessels in seventeen cases of interstitial nephritis. The vessels of the pia mater were the special object of investigation, as they could be examined directly in the tissue without teasing. The small vessels of other organs were not, however, overlooked.

The seventeen cases gave the following result:—

(1.) Thirteen cases had more or less developed genuine contracted kidney and were all accompanied by cardiac hypertrophy. Changes in the small arterioles could be recognized in all the cases but one, which was a case of glomerulitis.

(2.) Three cases had more the character of senile atrophy, although all were accompanied by changes in the vessels. Hypertrophy of the heart occurred in but one case.

(3.) One case showed a well marked old glomerulitis with quite recent round cell infiltration of the connective tissue.

Of the fifteen cases in which hypertrophied heart occurred there were six with no other changes in the circulatory system. In two cases there was valvular disease; while the remaining six showed chronic disease (atheroma or sclerosis) of the aorta.

The microscopic examination showed an increase of the adventitia and intima, while the muscularis was only affected secondarily, a fatty degeneration of the nuclei being observed. Similar changes were seen in the small vessels of the spleen and kidney, less distinctly in the liver and scarcely at all in the lungs.

The limited number of cases makes the author

¹ Articular Osteitis of the Knee in Children. New York Medical Record, January 31, 1880.

² Virchow's Archiv, vol. lxxxii, p. 212.

guarded in drawing conclusions as to the relations of cause and effect, but he calls attention to the fact that changes in the vessels do not follow all cases of granular atrophy of the kidney, and further, that in the two cases in which it was absent the condition known as glomerulitis (often found in the nephritis after scarlatina) was present. In six cases there was chronic endarteritis and as fifteen of the seventeen cases occurred in individuals of an advanced age, a period of life when arterial changes are most frequent, the changes in the small vessels may be considered as a partial appearance of general arterial degeneration. On the other hand, the fact is evident that arterial sclerosis and disease of the smallest branches does not always go hand in hand. In three cases the cardiac hypertrophy was not evident, although the thickening of the vessels was marked, thus showing that the increase in the walls of the arterioles was not dependent upon the greater blood pressure.

An experimental proof of the cause of hypertrophy of the heart has been undertaken by Israel,¹ who has fed rabbits with large doses of urea or nitrate of soda for many weeks, and found as result a hypertrophy of the heart and kidneys. He concludes, therefore, in the case of diseased kidneys, that it is the irritation of the secretions retained in the blood which leads to the enlargement of the heart. From these and previous observations, he thinks that the normal kidneys are sufficient, within quite wide limits, for any claims for elimination which may be put upon them, and it is only in extreme cases (in diabetes in men, and feeding on urea in rabbits) that an insufficiency of their activity occurs, varying in time with individual peculiarities. The products which thus fail to be eliminated act first in causing an increase in the heart's activity, and later, after long continuance, a hypertrophy. In what way this excitation is communicated to the heart, whether directly or through its nervous centres or through an irritation of the muscular coat of the small vessels of the body, the author is unable to determine.

Be that as it may, insufficiency of the kidney comes on much earlier, and the capacity of the kidney itself to hypertrophy is much less in a pathological than in a normal state. This is especially so in diffuse nephritis. In consequence, the increased activity of the heart will be called upon so long and to such an extent that the largest hearts will be here found that ever occur without valvular lesion or endarteritis.

THE HISTOLOGY OF GRANULAR KIDNEY

is the title of a paper by Dr. Saundby.² In this he agrees with Rosenstein, who considers both the large white kidney and the small red kidney as the result of a diffuse inflammation, that is, an inflammation involving both the parenchyma and interstitial tissue. He, however, believes that the epithelium lining the tubes plays a more important rôle than is generally ascribed to it. Instead of merely collapsing and being destroyed, the epithelium proliferates, and thus gives rise to the abundant small cells which have been described by Johnson as filling the tubules, and he figures the change of these into spindle-shaped cells, and finally into connective tissue. Instead of this there may be formed a gelatinous tissue with stellate cells in it, the origin of the little cysts first described by Simon. The basement membrane of the tubes merges itself in the

new-formed tissue. In the Malpighian bodies the changes consist essentially in the formation of embryonic connective tissue from the endothelium lining the capsule and covering the capillary tufts and subsequent atrophy of the vessels. In the arterioles the changes correspond with those already noticed by other authors, namely, a hypertrophy of the muscular coat in some parts, while in others there is an atrophy subsequent to the increase of the adventitia. The interstitial tissue proper is only affected to a slight degree, being only occasionally found filled with leucocytes, the result of temporary inflammatory action.

ACTINOMYCOSIS.

Pontick³ contributes three new cases of this disease, and in the introductory part of his paper gives a *résumé* of what is known on the subject. The disease was first recognized by Bollinger in 1876 as peculiar to cattle, since then it has been found affecting the human family.

In the ox it usually appears as a swelling near the angle of the lower jaw, which develops into a fleshy-looking growth, often slightly excoriated, and at first movable upon the parts beneath. Finally it invades the periosteum and pierces the bone in all directions. The soft parts with the jaw show a bulbous, fungous-looking mass, which may become as large as the two fists. In other cases it appears to proceed from within outwards. A more diffuse, tough infiltration attacks both the bones and soft parts, followed later by the outbreak. In the later stages the tumor increases in height above the skin presenting a large, uneven, ulcerating surface, which, however, does not secrete a large amount of pus.

A section reveals a soft, loose, and succulent mass, pervaded by numerous yellow spots. This consists of a connective tissue, rich in cells but poor in blood-vessels. No true pus is to be found anywhere, not even in the yellow spots, which are almost liquid, a condition due to a fatty degeneration of old inflammations and exudations. Besides this there is found, as a constant and never-failing characteristic constituent, a variable quantity of sulphur-yellow granules, the size of hemp seed, which are to be regarded as pathognomonic of the disease. These granules Hartz considered to be vegetable, and from their irregular, radiated, form proposed the name of actinomycosis for the disease. As a rule, in cattle, these tumors are not found in the internal organs.

The first clearly-described cases in men are given by Israel.⁴ Among them it also begins in the outer surface, usually about the face, but in the upper as well as the lower jaw. Its commencement is not always confined to this region, as Pontick reports one case where the thumb appeared to be the original seat. It occasions numerous communicating fistulae, which secrete little pus, but are filled with the remains of broken-down granulations and old, inflammatory, and exuded products. In this way the skin and subcutaneous tissue are undermined extensively, the muscles eaten into, and even the bony skeleton affected. Such is especially the case with the vertebrae, along which the granulation creeps, and from there invades the neck and thoracic viscera. To this continually progressing destruction the lungs are especially exposed, and as the disease is in its earlier or later stage there

¹ Virchow's Archiv., vol. lxxxvi., p. 299.

² Proceedings of the Pathological Society of London, vol. xxxi.

³ Berliner klin. ch. Wochenschrift, vol. xvii., p. 660.

⁴ Virchow's Archiv., vol. lxxiv., p. 15, and vol. lxxviii., p. 421.

is found a more or less extensive condition of hepatization mottled by numerous sulphur-yellow spots containing the above-mentioned characteristic fungus. At the same time both the cavity pleurae as well as the loose parapleural tissue is the seat of a purulent or phlegmonous infiltration, which is characterized by an admixture of fungous granules. The deep-laid organs, as the liver and spinal cord, are eroded at times, and finally destroyed by this continuously progressive malignant tumor.

Aside from this method of propagation a metastasis can take place by means of the blood-vessels. In one case it was possible to discover the point in the vena jugularis where the granulations had broken through the wall, and projected forward into the lumen of the vessel in the form of a little button. A soft tumor, the size of an apple, containing the same fungous masses, was found in the auricle of the heart, evidently developed from particles that had become detached from this node.

The clinical picture is confused, owing to the different parts attacked, and presents merely the results of a phlegmonous inflammation.

Besides cattle and men the disease has also been found in swine which are omnivora, but as yet not in the carnivora. Ponfick therefore concludes that a vegetable diet is in some way connected with its production. He further states that the local malignant character of this affection shows its difference from pyæmia and septicæmia, which have such an early tendency to become constitutional.

John¹ has found in the tonsils of twenty-one swine, with one exception, clumps of actinomyces in different stages of development, often already calcified, while the tonsil itself has presented no pathological change, and, above all, no formation of a tumor. Bits of barley and other cereals were also found on the tonsils, and on the barbs of the grain were to be seen gonidia, which were indistinguishable from those of the actinomyces lying near them.

Hospital Practice and Clinical Memoranda.

MALARIAL FEVER.

BY D. H. BATHURDER, M. D., ARLINGTON-IN-CRANSTON, R. I.

THE subject of *malaria* is now before the medical profession of New England in its most practical form. This unwelcome, though invisible, agent has in rather a surreptitious manner reappeared by way of self-introduction, making itself conspicuous in many localities in at least three of the States of New England.

But I am not disposed to treat the subject of Malarial Fever, further than to arrange and exhibit to the reader, in the simplest manner, the workings of *malaria* in my vicinity, just outside of Providence, R. I., for the last year, as I have been called on to attend, and if possible relieve, those who have been victims of the touch of this mysterious agent within my own circle of practice.

During the autumn of 1880 I was called on to attend four patients who were attacked with primary "ague chills and fever." Two of them proved to be severe and obstinate cases. The other two were rather milder, but they were all well defined, representing

every visible feature incident to the disease everywhere recognized as true "malarial fever." I was careful to note particularly every feature, as presented in these cases, type, symptoms, etc. But there being only four cases, I did not deem it advisable to make a report of them for publication.

I had no more cases of malarial disease until the fourth day of July, 1881, on which day I was called to see a patient who had been attacked with a severe chill. The man was suffering intensely. He had about got through with the chill and was suffering as reaction came on. This case was located not more than fifty rods from three of the four cases that occurred the autumn before; and it was a very severe case. From the day on which this patient was taken sick, to the 31st day of October, I was called to see, and attended, one hundred and twenty-eight patients at their homes, all of whom had chills and fever; and I prescribed for twenty more, who came to my office, having had one chill or more, but could be treated by directions given at the office.

AGES OF THE PATIENTS.

The number who had an attack between 1 and 10 years exclusive was	14
The number from 10 to 20 years	27
The number from 20 to 30 years	25
The number from 30 to 40 years	29
The number from 40 to 50 years	20
The number from 50 to 60 years	6
The number from 60 to 70 years	4
The number from 70 to 80 years	3

Making a total of 128

Not one of the hundred and twenty-eight cases whom I attended at their house, failed to fully represent the several stages, with all the physical symptoms usually exhibited in "fever and ague;" subject only to such modifications as may exist from variable habits, regimen, dissimilar constitutions, etc. Out of the whole number under consideration ninety-five were of the purely tertian type; and five more, though of the tertian, exhibited some freaky variations, which I deemed of sufficient importance to note down. A slight chill would occur on the second day, and skip the third. The case would then go along in the usual tertian form. Then there were twelve which were evidently of the tertian type, yet they had no real chill. Every alternate day the patient would pass through three distinct stages. The first stage would commence with a sensation of numbness, with the vital action largely suppressed, full and pressing cerebral sensations and also at the epigastric region, but no chilly sensation whatever. Then the fever would develop itself to some extent but in no way as severely as when it followed a chill, but the patients exhibited great distress, and in most of the cases they would vomit, and there would be a great deal of gastro-enteric hyperæmia. Then they would pass into what might be termed the third stage; did not sweat very much, but suffered apparently as severely as those who experienced the severest chill with febrile and sweating stages. On the whole, these patients did not recover in the same number of days that those did who had chills.

There were eleven cases of what is known as quotidian, with a regular paroxysm every day. Three of those exhibited some freaks, that is, in addition to the chill at twelve meridian a milder one would occur at midnight, skip over one day, then continue as at first in the regular quotidian form. There were three cases

¹ Centralblatt f. d. Med. Wissen.

of quartan type, with a paroxysm every fourth day; and two of what is known and recognized by writers as double quartan. These had a slight chill on the second day, and skipped the third.

There is in the circle wherein the malarial disease mostly prevailed quite a population of colored people; but I have been called to attend only one case, and that was a mulatto woman, who had malarial disease. So far as I have been able to observe its workings in this community, the Irish population has suffered the most, the natives the next in order, and the African the least of any class in the community.

During the month of July, subsequent to the fourth, I was called to attend eighteen primary attacks of malarial disease. Through the month of August I attended twenty-nine cases that were primary attacks during that month. During the month of September there were forty-four attacks; and through October there were thirty-seven. About thirty of the number took place during the first fifteen days of the latter month. Not an individual case has been brought to the notice of the writer on which could rest the least doubt in relation to a correct diagnosis. Every case was in its preliminary aspect ushered in by, and exhibited through the entire course of the disease, those distinctly marked symptoms and features peculiar to fever and ague the world over.

It is generally conceded by most writers, and practitioners as well, that fever and ague but seldom causes death, except in cases where some other disease joins with it to help complete its fatal work.

I am ready to give due weight to the opinions of authors in this view of the case; but shall abstain from any further remarks on this point at present, as my sole object in this imperfect report is to embody facts as they have been practically established in the course of my experience with the disease.

Out of the hundred and forty-eight cases of malarial disease, — or, if we include the four cases that occurred one year ago this autumn, the number would be one hundred and fifty-two, — in all that I have had to deal with, more or less, there have been two fatal cases. Right here, let me say, that I consider this point of so much importance that I wish to give quite an extended history of those two persons who died with malarial fever. They were both first visited on the same day; and both died on the third day after I made my first visit, the 22d day of October of the current year. The history of the two cases is as follows: —

CASE I. The first case was that of an old, retired merchant. He was born, always resided, and did business, in the city of Providence. He was seventy-four years of age. He had lived an extremely abstemious life in the strictest sense of the term; he had not used spirituous liquors in any way whatever; he had for many years abstained entirely from meat diet, neither had he used tobacco in any form, and had scarcely ever during his life taken a dose of medicine. He was seized with ague chills, but would not consent to have a physician sent for till the seventh or eighth day of his illness, when he reluctantly gave his consent. On my first visit I found him in a semi-collapsed condition; he had had chills and tertian fever of the severest kind up to that day, but had taken nothing of a remedial kind except a very little ginger tea; he had just experienced a severe rigor, but there did not seem to exist sufficient vital force to bring about the usual reaction; his legs and feet were very cold, his hands and arms

were cold, his nose and ears were cold, and he exhibited great distress all about the gastro-hepatic regions; no pulsation could be felt at the wrist, neither was the second sound of the heart distinctly audible.

Notwithstanding this suppressed and negative condition, with his vital forces in a manner far spent, his mind showed evidence of clearness and equanimity. His answers were intelligent and correct.

In this state of things I concluded that he had passed by the time for the treatment I should have rendered had I seen him in the first or primary stage of his illness; consequently there seemed to be no other alternative but to administer the most appropriate diffusive stimulants, with as large a quantity of quinine as the condition of his stomach might tolerate. But his vital forces were so low that the system was totally unable to respond even to the most active heroic treatment, and he died.

Now, in this case there was no visible sign or symptom indicating the auxiliary effects of any other disease that might help to destroy life. It is true that his advanced years might play some part in the result, yet when we consider how well he had been, and the physiological balance of his whole fabric which had apparently existed down to the time of this malarial attack, I do not see how we can charge old age in this case as being a very *important factor* in the destruction of life. I did not hesitate to sign his certificate of death as from the effects of "malarial fever."

CASE II. The other fatal case was a man about thirty-five years of age. He had all his life been healthy and robust; was born in Ireland, but had resided in this country a series of years; he was a blacksmith by trade, and on the whole was an industrious man; while engaged in his shop he had indulged largely in the use of beer, though not neglecting his business; he also, like the first case, had previously been sick but little, and had taken little or no medicine; he also was seized with ague chills and fever; he did not take proper care of himself, and his fever being of the tertian kind on the day of apyrexia he continued to go to his shop, and to drink beer and some other liquors in increased quantities for two weeks or more, the chills and paroxysms of fever becoming more intensely severe all the while. Finally his friends persuaded him to call at my office. It was with some difficulty that he was able to reach the office. He wore a ghastly appearance, and on examination I found his pulse beating in a throbbing manner, 130 per minute; he complained of acute pains in the head, shoulders, back, and lower limbs, attended with a hyperæmic condition of the stomach and probably of the duodenum.

I directed him to return home at once, and get into bed, and said I would follow him immediately and pre-scribe for him.

On my visit I found him considerably nauseated, greatly debilitated, with rather a suppressed condition of the superficial capillary circulation; his feet and legs, hands and arms were inclined to be cold, and the stomach disposed to eject whatever he took into it. I was informed by his wife that he had taken but very little food for two weeks or more; he had, however, drank fully two quarts of lager beer every day during that time; he had had a chill every other day, in the morning, for nearly three weeks, and he had one that morning before he called at my office, but the usual reaction did not take place. He had not before

or at the time I first saw him, exhibited the remotest appearance or symptom of any other disease in connection with malarial chills and fever.

He was treated heroically with hot brandy and ammonia with quinine, but his vital forces were too much exhausted to be acted upon by medicine, his heart ceased its struggling, and he died.

I know of nothing that could have had any influence in urging this case on to its fatal results except his own neglect to use means in season to modify and check the progress of the disease. It is an unsettled question as yet whether or not such free use of beer and other stimulating drinks serves to hasten on or retard the disease in the final consummation of its fatal work. I am unable to assign any legitimate cause, remote or proximate, for this man's death other than malarial fever.

I have been thus particular in narrating the sickness and demise of those two persons, as there has been some inquiry expressive of doubts in relation to the death of the second case narrated, some intimating that he died from typhoid fever and not from malarial fever. Now I desire to state frankly that during the time, three days, that this case was under my care and attendance there was not a symptom that portrayed the slightest indication of typhoid fever. And here allow me to say that not only was this case exempt from such features, but every other case was likewise exempt from the well-defined symptoms of typhoid fever. I desire, before I close, to say, also, that in my next article in continuation of this subject I shall speak more fully upon that part of the subject which more particularly relates to the connection of malarial with other zymotic or epidemic diseases, as observed and noted during my experience in the phenomena and treatment of this most of all others insidious disease, malarial fever.

In my next I shall describe the surroundings or territory wherein this zymotic has so generally prevailed, its connections with the city of Providence, and the course of treatment I have adopted.

THE TREATMENT OF HYDROCELE AND SEROUS CYSTS IN GENERAL BY THE INJECTION OF CARBOLIC ACID.

THE employment of carbolic acid for the purpose of obliterating the cavity of a hydrocele of the vaginal tunic of the testicle by Dr. R. J. Levis, of Philadelphia, has previously been referred to in the JOURNAL, and has been mentioned by him repeatedly in his clinical lectures during the last ten years; until the last meeting of the Pennsylvania State Medical Society, however, he had not formally brought it before the notice of the profession. After more than nine years' exclusive practice of this method in the treatment of hydrocele in hospital and private practice he still endorses it fully and recommends its general adoption.

The object of treatment sought after is the obliteration of the serous sac by plastic inflammation, and still to avoid suppuration caused by the seton or the more irritant injections. The suppurative process being condemned, while the ordinary fluids used for injection are too uncertain in their results, Dr. Levis was led to try pure carbolic acid to secure adhesion of the walls. The process is entirely painless. The details of his method and its results are best given in Dr. Levis's

own words. It is seen that whereas he formerly used the pure carbolic acid he now prefers a permanent solution.

"For the purpose crystallized carbolic acid is maintained in a liquefied state by a five or ten per centum addition of either water or glycerine, the quantity of the diluent to be added varying with the quality of the article and with the temperature of the apartment; but it is an object to reduce the crystals to a fluid state with no more dilution than may be necessary. Liquefaction could readily be effected by the application of a moderate amount of heat, but reduction of heat might produce solidification of it in the canula.

"After the usual tapping of the sac I inject the liquefied crystals of carbolic acid with a syringe having a nozzle sufficiently slender and long enough to reach entirely through the canula. The illustration represents the syringe, reduced to one half the proper size. The object of having this special form of instrument is to insure the placing of the injecting material entirely within the cavity of the cyst, without any reflux which would irritate the surface of the skin of the scrotum or of the fingers of the operator, and without the possibility of injecting it into the connective tissue between the skin and the tunica vaginalis. This form of syringe is supplied by the leading surgical instrument makers.

"The quantity injected varies in accordance with the size of the tumor, from thirty to sixty grains. Thirty grains of undiluted carbolic acid is the smallest amount that I have used, and the largest quantity a drachm and a half.

"As soon as the carbolic acid is lodged within the sac the scrotum is freely manipulated by the fingers of the operator, so as to diffuse it over the lining walls of the hydrocele. A sense of warmth is produced, which is quickly followed by a decided numbness, and the patient is at once able to walk about and to attend to his ordinary duties without inconvenience. I have not been in the habit of enforcing rest on the patient until after the lapse of twenty-four hours or a longer time, when intra-serosal inflammation renders quietude agreeable or imperative.

"I have never, after this procedure, been able to detect any general toxic effects from the absorption of carbolic acid. Such systemic manifestations as general depression and the characteristic evidence of the brown discoloration of the urine I have looked for, with negative results. I believe that the action of strong carbolic acid on surfaces secreting albuminous fluids is to seal them, and, as it were, to so shut them off from the system that absorption cannot readily take place. This sealing of an absorbing surface involves a surgical principle in antiseptic treatment which is applicable in very many instances in which denuded or ulcerating surfaces are exposed to septic infection. I state it as an important surgical resource that, in certain compound fractures and destructively lacerated wounds, where septic exposure is inevitable, the danger from absorption may be averted by producing the occluding influence of strong carbolic acid.

"Within my own experience no failure to radically

cure hydrocele in the manner I present has to my knowledge occurred. I have never failed to produce with carbolic acid the proper amount of inflammation within the walls of the sac, but have been informed that such failures have occurred in other hands, yet do not know the particulars of the treatment and results in those cases. In no case of hydrocele or other simple serous cyst have I seen inordinate inflammation or suppuration follow injection. In a case of cyst within a disorganized testicle, which was probably sarcomatous, treated with the injection of carbolic acid, high inflammation and suppuration occurred. In three instances of hydrocele of the tunica vaginalis testis, in which the previous injection of the tincture of iodine had failed, carbolic acid made a permanent cure."

Dr. Levis also considers this treatment as eminently applicable to the treatment of mucous and serous cysts in general, such as enlarged bursae, cystic growths of the neck, intra-scrotal cysts, etc. Housemaid's knee and miner's elbow he believes would be best treated, however, by free incisions, mopping the surface with pure carbolic acid, and packing the wound with a compress of carbolized oil and charpie.

Reports of Societies.

NEW YORK SURGICAL SOCIETY.

EMPYEMA; PARACENTESIS THORACIS: RESECTION OF THREE RIBS; SPEEDY RECOVERY.

STATED meeting, October 25, 1881. DR. H. B. SANDS, president, in the chair.

DR. LANGE presented a patient with the following history:—

Mr. W., forty-two years of age, suffered from pleurisy two years ago, and after a severe illness of three months retained an effusion in the left thoracic cavity, reaching nearly to the angle of the scapula. He carried the fluid without great discomfort. Dr. L. Conrad had ascertained, by exploratory puncture, that the fluid was serous. Three months ago the patient began to lose flesh, lost his appetite, and had more or less pain in the left side. About two months ago Dr. Conrad recognized the danger incident to the suppuration, and asked Dr. Lange to perform the necessary operation, which was done on the 18th of August, and consisted in resection of the seventh, eighth, and ninth ribs in the posterior axillary line, to the extent of one and one half to two inches subperiostally, and the eighth and ninth ribs were resected from *one* cutaneous incision. The opening into the thorax was made from the periosteal bed of the ninth rib, and at a right angle another cut was made upwards into the periosteal bed of the eighth rib. About a quart of pus escaped, mixed with abundant soft fibrinous coagulations. The pleura was about one centimetre in thickness, the diaphragm drawn upward, the lung could just be reached with the finger. It was covered by hard resistant pleura, and did not move at all during the act of respiration. The cavity was washed out with thymol, one to one thousand, and an antiseptic dressing was applied, which had to be changed, first every two, later on, every three to four days. After four weeks the discharge was quite insignificant, while the upper wound, where the seventh rib had been resected, had healed by primary union. After seven weeks cicatrization was complete, and the

lower part of the left thoracic cavity was diminished in circumference and flattened. At present the resected ribs seemed to have regained their continuity, but narrow ridges indicated the places where the bones had been resected, and the ribs themselves yielded easily to pressure. The patient had resumed his work as a carpenter, and was in a good general condition. A moderate degree of ascites, which existed from the beginning, had not changed. The urine contains no albumen.

DR. BRIDGEMAN thought that it was not absolutely necessary to make an opening into the thoracic cavity at the most dependent portion, with the idea that by so doing the most complete drainage could be secured; for it was so difficult to keep the opening patent, on account of the persistent tendency to contraction, that a collection of pus would form despite the low incision; it was exceedingly difficult to keep such wounds aseptic. He regarded the recommendation of Mr. Bryant as the best, namely, that the opening be made in the axillary region on a level with the nipple. By making the incision in that region the tendency to contraction, which existed when it was made near the angle of the ribs, was in a very great measure avoided. The intercostal spaces were wider and there was less disposition of the ribs to overlap. Latterly he had used a solution of common table salt (recommended in Ziemssen's *Encyclopædia*) as an antiseptic injection in this class of cases, and with satisfactory results, after having made an opening, in the ordinary manner, between the ribs, and inserting a drainage-tube, and he had found a large sized hard rubber trachea tube answer very well.

DR. LANGE remarked that he had been aware of the tendency to close which the opening manifested when made low down, and, therefore, had increased its size by cutting upwards from the original wound into the place where the rib had been removed.

DR. POST thought there was no difficulty in maintaining the patency of the opening when a portion of the ribs was removed.

THE PRESIDENT regarded the result in Dr. Lange's case as excellent, although it might seem that the operation was a severe one. He had effected cures, as had Dr. Bridgeman, by making an opening between the ribs, inserting a drainage tube, and keeping the cavity cleansed; but was unable to recall any case in which complete recovery took place within nine weeks.

DR. MARKOE referred to two cases, in the New York Hospital, in which the thoracic cavity had been opened for empyema. In one case, treated under the strict Lister plan, the patient was well at the end of seven weeks. The second patient, whom Dr. Markoe himself operated upon, had advanced phthisis; he was treated by "thorough drainage." The rapid progress of the case downwards was arrested by the operation for the empyema, and both the man and the wound in his chest wall were doing well. In the second case the cavity was washed out at first with a solution of carbolic acid, one to one hundred, and afterwards with thymol, one to one thousand.

Both patients were adults. In his own case the lung was bound down extensively and had expanded to only a very slight extent. In the first case when no complication existed the expansion of the lung had been very complete.

DR. LANGE thought that in his case the lung had not expanded at all. Nor did he think that it should be expected that it would, because the pleurisy had

been of so long standing and the adhesions had become so thick and firm, which held the lung in its abnormal position. He regarded the prognosis, concerning ultimate recovery, as much more favorable in cases like the one reported than in cases of acute empyema, because the surrounding tissues were in a condition that favored the supply of sufficient material to fill the cavity.

In acute empyema or empyema associated with lung disease, the conditions for a favorable result were not so good as in chronic uncomplicated cases, and in that way rapid recoveries could be explained.

Dr. L. A. STIMSON referred to the case of a child, four or five years old, in which, from two ribs, pieces of bone about an inch long were removed. There was a cavity of considerable size, the lung was contracted, and showed no tendency to expansion. The empyema had existed about a year and a half when the operation was performed. He had an opportunity to examine the patient about two months after the operation, and although the general condition had greatly improved, there remained a cavity of considerable size in the chest and the lung had not expanded.

COMPOUND COMMINUTED FRACTURE OF THE FRONTAL BONE.

The PRESIDENT presented a patient, thirty years old, who entered the Roosevelt Hospital on the 28th of May, 1881. Just previously to admission he had been injured by the bursting of a "steam pot," a fragment of iron striking him in the forehead and producing a compound comminuted fracture of the frontal bone. The long diameter of the fracture and the gap in the skull was more than three inches and the vertical diameter one inch and an eighth. The patient was seen first by Dr. Hume, the house surgeon, who removed, by means of an elevator and Rongeur forceps, many pieces of bone, and left an opening in the skull of the dimensions given. It was noticed, on removing the pieces of bone, that the dura mater was injured in two places, and that from one or both of these places a small quantity of brain had exuded.

No severe symptoms followed the accident. At first the wound was treated antiseptically. It was carefully washed out at the beginning with a strong solution of carbolic acid, the subsequent dressings for some time were applied under spray, and the Lister treatment was followed strictly.

On the sixth day after the injury it was found that the union which had occurred had broken down and there was some indication of protrusion of the brain. Within the few days immediately following the protrusion attained a considerable size, and overlapped the margin of the opening in the bone. There was considerable discharge from the wound, which was so fetid that applications of various substances were made for the special purpose of correcting the odor. At no time did severe head symptoms exist. The patient had headache occasionally, but no delirium, and never a very high temperature.

The interest in the case rested in the fact that the patient went on slowly but steadily towards recovery, which took place under the use of iodoform, freely applied to the swelling, over which an ordinary bandage maintained a moderate amount of pressure. Very slowly the tumor diminished, finally disappearing, and allowing the wound to cicatrize. The patient left the hospital on the 21st of September. On examination

the pulsation of the brain could be seen through the cicatrix.

The president asked for the experience of the members in cases of hernia cerebri, and the modes of treatment which they had adopted.

At one time he was tempted to interfere with the tumor, and to shave it off, but from the time he began to apply the iodoform, which thoroughly removed the odor and dried up the exudation, he abandoned the idea of active interference.

Dr. G. A. PETERS said that the president's case was almost exactly parallel with one which he had in the New York Hospital, except that the patient was an older man. In that case the treatment was chiefly pressure and antiseptic dressings, and a good recovery took place. At about the same time he had another case in which the wound was in the parietal region. A considerable portion of bone was removed, but there was much less hernia cerebri than in the first case. At one time some of the protruding mass was shaved off, and pressure was applied. The patient recovered. He attached much importance to pressure in the treatment of these cases.

Dr. A. C. POST had seen several cases of hernia cerebri in which recovery followed the use of pressure and the nitrate of silver.

Dr. MARKOE had had several cases in which pressure and the free use of the nitrate of silver had been attended by rapid recovery.

Dr. POST remarked that statistics showed a greater proportion of recoveries in young subjects than in adults.

The PRESIDENT said that it would be interesting to know in what class of cases recovery occurred most frequently, whether when the injury was in front or elsewhere.

Dr. WEIR saw Dr. Sand's case in July, and at that time the mass seemed to be in a sloughy condition.

In studying the subject it might be well to bear in mind the three forms of hernia cerebri, namely:—

First, that in which the tumor is composed of disorganized brain substance, as proven by microscopical examinations by Drs. Chark, Draper, and others.

Second, that in which the brain is protruded by the pressure of inflammatory processes—in such a case as this Nélaton luckily struck the abscess by plunging into the brain a bistoury, Detmold also evacuated pus in a similar manner, but his patient died later.

Third, that in which exuberant granulations spring from the damaged brain substance.

Many years ago he was engaged in the preparation of a paper upon hernia cerebri, and at that time collected fifty-five cases of this complication, and from a study of such cases it was determined that it was not a necessarily fatal complication, as out of this number thirteen recovered and forty-two died.

The treatment mostly satisfactory in the successful cases was slicing off the protruding mass, and applying caustic and compression subsequently. No trouble ensued as a consequence of the caustic, though pressure sometimes produced decided cerebral symptoms. But in two or three cases seen in later years he had not done anything with the tumor except to use deodorizing applications, and it had gradually sloughed off, contracted, and disappeared. The attempt to penetrate a possibly subjacent abscess or to let out adjacent pus was of but little avail in the cases due to meningitis or encephalitis. Hernia cerebri occurred

in a collection of one hundred and twenty-eight cases of various fractures of the skull only ten times, or about eight per cent., and in fifty-seven operations for trephining it occurred fourteen, or one in every four cases.

DR. L. A. SRIMSON had seen one case in Bellevue Hospital in which the hernia was upon the top of the head, and about eight centimetres in diameter. It was diminishing in size under pressure but he was unable to give the final result.

DR. LITTLE had seen three cases, one over the frontal bone and the others over the parietal. All three patients recovered under the use of nitrate of silver, dry chalk, and a bandage. In one of these cases there were the following interesting features: A child received an injury upon the head, and although the physician in attendance recognized a compound fracture of the skull, he let the patient alone, because there were no head symptoms present. Some weeks afterwards symptoms of compression developed, and there was strabismus and convulsions. Ether was administered, and Dr. Little removed several pieces of bone. The dura mater was uninjured. He then incised the dura, but no pus was discharged, and he then punctured the brain substance and found an abscess. Pus discharged freely, and the symptoms of compression were very much relieved. The child did well until a week or ten days afterwards, when hernia cerebri made its appearance, and the protruding tumor attained to considerable size. Pressure and the dry chalk powder were applied, and during that treatment convulsions and coma developed, but passed off, and the patient ultimately recovered entirely.

DR. MARKOE thought there were two forms of this affection, one of which was almost necessarily fatal. In that fatal form there was a condition of suppuration of the brain tissue itself, and discharge of pus from the more central portion of the cranial contents.

In such cases pressure would not be tolerated, and the outward protrusion was only an indication of the bad condition within, the protrusion consisting of flabby granulations from the suppurating and broken-down brain substance. In the other form the tumor contained no brain substance whatever, but merely granulation substance.

The PRESIDENT thought it was a well-settled fact that brain tissue did form a part of the tumor in these cases.

DR. YALE referred to a case in which a boy, six years old, received a compound fracture of the parietal bone. The fragments of bone were removed, and afterwards hernia cerebri developed, which receded under treatment, and, later, again appeared. The surface of that tumor was composed of granulation tissue. It was treated by pressure, but not successfully. The boy recovered sufficiently to go about, and one day, after having played quite freely, symptoms of meningitis supervened, and terminated fatally within two or three days.

DR. MCBURNEY referred to a case which illustrated the more serious affection mentioned by Drs. Markoe and Weir. A child, ten years old, received an injury upon the left side of the head which involved nearly the entire parietal bone, and also injured the brain extensively. The patient lived several weeks, and during that time granulation tissue developed so abundantly that a tumor was formed sufficiently large to overhang the edges of the opening in the bone nearly an inch in extent. After death the mass almost en-

tirely disappeared. Microscopical examination showed that what remained contained little or no brain substance. There was no abscess.

OSTEOMYELITIS ACUTA SPONTANEA, TREATED AFTER KOCHER'S METHOD; GOOD EFFECT OF THIS PROCEDURE; FINAL RECOVERY AFTER NECROTOMY.

DR. LANGE presented a patient with the following history:—

A boy, ten years of age, was attacked without apparent cause by acute osteomyelitis of the left tibia. He was called in consultation by Dr. Lauer, of New York, and saw the boy on the tenth day of the disease. There existed every feature of a pretty severe osteomyelitis of the upper half of the left tibia, with moderate affection of the knee-joint and marked subperiosteal effusion, especially on the inner and posterior side of the bone. No other bone or joint was affected. On the following day the pus was aspirated, and the pus cavity washed out by about twenty repeated injections of a warm two and one half per cent. solution of carbolic acid. The limb was elevated and ice applied constantly. The local and general effect were quite marked. With the internal use of salicylate of soda the fever fell considerably and the hitherto extreme pain ceased almost entirely. The pus did not gather again, though about two ounces had been withdrawn at the first occasion, and without manifest suppuration that board-like, hard infiltration occurred, which we are accustomed to see in cases of osteomyelitis during the time the involucrum is formed. It was not until at the end of the third month, and apparently then in consequence of the restlessness of the otherwise healthy child, that perforation of the skin occurred. This, however, took place almost without suppuration. A cushion of granulations gradually attenuated the integument, finally absorbing it, and more serous than purulent discharge took place. In the fourth month necrotomy was performed. In order to get at the sequestra lying on the posterior side of the bone a good deal of the anterior and lateral part of the latter had to be removed. Dr. Neuber's plan was adopted in sewing up the integument after thoroughly cleansing the bone cavity. Then the absorbable drainage tubes were inserted, and the permanent antiseptic dressing was applied. Ultimately the elastic bandage was removed, and the limb kept in an elevated position for several hours. Only a few dressings were applied within the first two months, when cicatrization was complete, and also internally the cavity seemed to be so solidly healed that the use of the limb was justified. There remained an almost linear scar, about five inches long, above the internal edge of the tibia, whose outlines were perfectly faultless. It might be added that the affection of the knee-joint ended almost instantly after the original operation of washing the cavity with the solution of carbolic acid. The use of the limb is now entirely unimpaired.

OSTEOMYELITIS ACUTA OF THE UPPER END OF THE HUMERUS; SUPPURATION OF THE SHOULDER-JOINT; BONY ANCHYLOSIS AND RESECTION OF THE SAME, TOGETHER WITH NECROTOMY; RECOVERY; USEFUL LIMB.

DR. LANGE also presented a patient and specimen with the following history:—

The patient had been presented about two years ago to the New York Pathological Society.¹ In this case

¹ See Medical Record, 1879.

the left hip and right shoulder were affected by the osteomyelitic process, but only at the shoulder did it develop to its full intensity. The patient, a girl of now eighteen years, is able to do heavy housework, though the elevation of the arm was possible only to a slight degree. Still she was able to use the arm in eating and in washing her face. Movements forwards and backwards were free and vigorous. A point of interest in the excised head of the humerus was the elongation of the medullary canal upwards nearly to the epiphyseal line. From its upper end two wide canals led outwards, and it contained a small encysted abscess, lined by dense fibrous tissue, which completely filled the medullary canal. The epiphyseal cartilage had entirely disappeared except a few small spots of about the size of a pin's head. The cancellous tissue of the head of the humerus was in a state of rarefying osteitis. The small amount of elevation of the arm possible in this case was probably due to the intense atrophy of the scapular muscles, which, in spite of all possible means, had been but slightly improved.

MULTIPLE OSTEOMYELITIS INVOLVING MOST OF THE LONG AND SOME OF THE FLAT BONES OF THE BODY.

DR. LANGE presented a patient with the following history:—

A man, now more than forty years of age, was attacked by the disease when ten years old. He ascribes the origin of it very distinctly to the influence of wet and cold. He had jumped into deep water, and remained in his wet clothes more than half a day, because he was afraid to return home. On the following day he was taken with pain, first in his left hip, which gradually went lower down, and was most intense about the knee. From the second day he does not recollect anything, and he only knows that he passed through a long and very serious disease, and that his left tibia and left humerus were operated upon. After three months he was sent to the baths of Wiesbaden, and after that he was able to walk on crutches. During the following winter suppuration occurred in different bones of the skeleton, while heretofore, in the original acute attack, only the left tibia and humerus had been affected. From those two bones only and the left femur had dead bone been removed in the course of years. The patient presented a real standard-mass of bone cicatrices all over the body, and at several spots interesting consequences upon the development and growth of bones.

The left ankle-joint was stiff and in slight varo-equinus. The tibia was several centimetres shorter than that of the other side. The left humerus was eight centimetres shorter than the healthy one of the opposite side. There was marked deformity in the region of head of the humerus pointing to epiphysitis. The shoulder-joint was movable, but not to the normal excursion, and allowed elevation of the arm somewhat above the horizontal line. In later years the patient had suffered from a fracture in the middle half of this same bone, and part of the shortening might be attributed to this circumstance. Besides the bones mentioned the following presented the marks of former suppuration in the shape of deep and more or less extensive cicatrices, the left clavicle, right scapula, femur, and tibia, several ribs of the right side, and the left ilium near the synchondrosis sacro-iliaca. The man is now very healthy, and rather stout and

ABSCESS OF THE TIBIA; PREVIOUS OSTEOMYELITIS.

DR. LANGE presented a patient with the following history:—

A woman, fifty-two years of age, was operated for large bone abscess in lower third of tibia, where, forty years previously, an apparently osteomyelitic process had existed. She mentions that after a long and serious illness in her thirteenth year bones were taken away from that very spot. The symptoms of bone abscess began to develop a year ago, and gradually increased to unbearable pain, especially toward evening. The operation was performed after Dr. Neuber's plan, and healing took place within ten weeks with a narrow cicatrix. An extensive cavity had to be formed in the lower third of the largely hyperostatic bone until healthy but sclerotic bone was reached. Use of limb unimpaired.

BONE ABSCESS IN THE HEAD OF THE TIBIA, WHICH IN FORMER YEARS HAD PROBABLY BEEN THE SEAT OF CHRONIC OSTITIS.

DR. LANGE presented a patient with the following history:—

A man, fifty-one years old, tailor, German by birth, had chronic trouble with his right knee-joint when a boy. The joint became completely stiff, the tibia became deformed, presenting an angular, bayonette-like deviation, due, without any doubt, to epiphyscolysis. The limb, however, was useful for almost forty years, when a severe inflammation occurred about the knee-joint, and especially the head of the tibia, which required a number of incisions, leaving fistulae, which led down to the bone. The patient tells that he was in high fever for four weeks, and though the physician who treated him called the disease erysipelas it might be certain that an acute ostitic process had been going on in that bone, which, during childhood, had been the seat of a chronic affection. The operation consisted in laying open the cavity which almost entirely occupied the abnormally large head of the tibia, containing at the same time a standing sequestrum of cancellous tissue. Deep incisions had to be made into the popliteal fossa in order to lay open the fistulous track and abscesses, and to remove fungoid granulations. The operation was done a year ago, and four months later the patient resumed work. The cavity was not yet entirely filled, and a deep canal leads into the head of the tibia. The cicatrix seemed, however, to cover a part of its track, and there was hardly any secretion present. The patient suffered no inconvenience.

DR. POST mentioned the case of a boy fourteen or fifteen years old who had acute inflammation involving the principal bones of the extremities,—both arms, both thighs, and one leg. There was enormous swelling, with very active inflammation, which proved fatal.

Several years ago he saw a boy fourteen years old, who was attacked with what was thought to be rheumatism. At the end of three weeks Dr. Post saw the patient, and found that one of his arms was the seat of acute inflammation, with suppuration at about the junction of the shaft of the humerus with the upper epiphysis. He made an incision, evacuated a considerable quantity of pus, found the upper part of the shaft of the bone denuded, and he excised a portion about four cm. in length. The remains of the humerus became attached to the epiphysis, and the patient ultimately had a good arm.

In addition, the patient had inflammation involving

the ulna near the wrist, but that recovered spontaneously. There was also severe inflammation involving the upper part of the shaft of the tibia and the epiphysis, and finally it became necessary to perform amputation. The head of the tibia was carious, and there was at the same time a sequestrum imbedded in the spongy tissue of the bone. The case was remarkable for rapidity of its course.

At about the same time he saw another boy who had had the disease for a year or more. It involved three or four bones, and led to necrosis, which was more chronic in character. The patient entered the Presbyterian Hospital, where Dr. Post had occasion to operate several times, but ultimately a recovery was made.

DR. LANGE remarked that an interesting feature of his last case was that most of the bones were affected secondarily. Secondary osteo-myelitic processes had been observed only rarely.

DR. BRIDGON asked whether the secondary manifestations had a direct relation with the primary affection or were both due to a general condition of the system.

DR. LANGE thought it must be assumed that foci of morbid material must have remained in the system, and under certain conditions manifested themselves in inflammatory action. Sometimes the interval between attacks might be twenty or thirty years. The later attacks were most severe, and the prognosis in secondary osteo-myelitis was unfavorable.

DR. POST remarked that primary attacks were almost entirely confined to persons who had not entirely obtained their growth.

DR. LANGE said that was so much the case that one author had described the affection as an "osteorheumatic inflammation of the youth."

DR. WEIR alluded to the difficulty of determining the nature of the disease in its early stage, for he had seen recently two cases of multiple osteitis in which he was unable to make a diagnosis until the disease had progressed for some time. It was only when the abscesses began to show themselves that he could reach a positive conclusion concerning the nature of the affection with which he had to deal. It was likely to be confounded with rheumatism.

With reference to interference with the subsequent growth of the limb his impression had been that after osteo-myelitis involving epiphyses had progressed to the extent of separation of dead bone and the opening had closed, the growth of the limb would not be of necessity interfered with. This had been met with in several instances where shortening had been anticipated but had not occurred. In all probability the inflammatory process had not destroyed to any great degree the epiphyseal cartilage, though a sinus led to and through it to the necrosed bone.

DR. LANGE thought that the growth of bones after osteo-myelitis depended very much upon the parts involved by the disease. If the process did not at all involve the epiphyseal portion growth would not be affected.

DR. STIMSON referred to a case recorded by Bryant in which fracture of the shaft of the humerus was sufficient to arrest development.

THE PRESIDENT remarked that it was difficult to conceive that the growth of bone could continue to much extent after the epiphyseal cartilage was destroyed.

DR. STIMSON referred to two cases of arrest of development, quoted by Marchand, after separation of the lower epiphysis of the radius.

DR. LANGE remarked that the credit had usually been given to Chassaignac for having first described osteo-myelitis; but he had been interested in an elaborate article written by Dr. Nathan Smith, of Baltimore, in 1831, in which the clinical features of the disease were described in a very striking manner. Dr. Smith mentions several cases in which he trephined bones and found small abscesses scattered through the marrow. His first case was observed in 1798.

RUPTURE OF THE ADDUCTOR LONGUS MUSCLE; TUMOR SIMULATING THE APPEARANCE OF A FEMORAL HERNIA.

DR. MCBURNEY presented photographs accompanied with the following history of the case:—

H. M., thirty-three years of age, was admitted to one of his wards at Bellevue Hospital on the morning of May 30th. He was suffering from several slight cuts and contusions received in a street fight a few hours before admission. What particularly attracted Dr. McBurney's attention was a tumor situated just below Poupert's ligament on the right side, in the ordinary situation of, and very accurately resembling, a femoral hernia. The tumor was three inches long by two wide, and the patient was positive that no enlargement of any kind had ever existed in that situation before the night on which he had received his injuries. The tumor was slightly tender on pressure; it was dull on percussion; no impulse was given to it by cough. No vomiting had occurred. There were absolutely no signs of contusion of the thigh, and no change in shape at any part. There was no indication for surgical interference. On the next day he noticed a very shallow, broad depression on the inner aspect of the thigh, occupying about the middle third. That made him think that possibly the tumor was the upper end of a ruptured muscle. One of the house-staff, Dr. Hartley, had already asked if such might not be the case. It was not difficult to establish the character of the swelling. He applied to either side of the tumor one of the poles of a galvanofaradic battery, and at once the contraction of muscular fibre throughout the whole mass was very easily appreciated by both the eye and the finger. By holding the limb firmly abducted, the patient attempting to adduct it, considerable contraction of the tumor took place. It was then easily determined that the tumor was formed by the upper contracted end of the adductor longus muscle, which had been ruptured.

DISLOCATION OF THE LOWER JAW.

DR. POST narrated a case as follows: A young woman presented herself at his college clinic unable to close her mouth. The history was that she had had a molar tooth extracted thirteen days previously, and, according to the patient's statement, the patent state of the mouth did not exist immediately after the tooth was removed but first appeared a short time subsequently. At all events there was dislocation of the lower jaw following the extraction of a tooth. The mouth was not as widely open as it usually is in these cases, the teeth coming together within about two centimetres, and the lower jaw projecting in front of the upper one. There was also less of a hollow in the region of the glenoid cavity than is usual after dislocation.

It is a question whether, in ordinary dislocation of the lower jaw, the inferior maxillary is dislocated *from* the interarticular fibro-cartilage, or carries it *with* it. His impression was that, in ordinary cases, the dislocation was *from* the cartilage, and it might be that the dislocation in the case reported was *with* the interarticular fibro-cartilage, which did not allow displacement of the bone to the extent usually present in the ordinary form of the injury. The dislocation was reduced in the usual manner. Dr. Post asked whether any of the members could give definite information concerning the position of the interarticular fibro-cartilage in dislocation of the lower jaw.

DEFORMITY OF THE NOSE CAUSED BY ULCERATION.

Dr. Post also exhibited photographs representing a deformity of the nose resulting from ulceration. The patient was a woman fifty years of age, who suffered from an ulcer involving the right side of the nose, that gave rise to the deformity about twelve years before presenting herself for treatment. The patient was in apparently perfect health, and the ulcer had been perfectly healed for a number of years. Dr. Post performed a skinoplastic operation, taking the flap from the corresponding cheek, and curving its peduncle so as to remove the tension, and the result was a filling up of the deficiency, an improved condition of the appearance of the patient, although the opening of the nostril was not restored.

HIP-JOINT DISEASE; MUSCULAR CONTRACTION.

Dr. Post also narrated a case with the following history: A girl, six years old, was brought to him with the statement that, two years before, she was supposed to have hip-joint disease. She had the symptoms of the disease at the age of four years, was under the care of Dr. Sayre, who used his splints with marked benefit for several months. At the end of that time the splint not only did not relieve the child, but she felt worse whenever it was applied, and consequently it was removed entirely. The limb was then kept at rest for some time, emollient applications were made, and the patient seemed to be doing well. Of late there had been no symptoms indicating inflammation about the joint, but the child has not been able to walk with any freedom. On careful examination Dr. Post found the following condition of affairs: There was no marked difference in the length of the two limbs. There was perfect freedom of motion in the direction of flexion. The head of the femur could be pushed against the acetabulum without causing pain, and pain was not produced by pressure over the trochanter. On attempting to extend the limb it was found that, although the thigh could be brought down, the movement was not between the femur and acetabulum; it was the motion of the pelvis which permitted the extension.

On further examination he found that the real obstacle to extension of the limb was apparently confined to the tensor vaginae femoris and the sartorius muscles, and the resistance which they offered was marked. He also found that the obstacle to abduction was the tense gracilis muscle. The limb could be adducted. He regarded the case as one in which the original disease was hip-joint disease, which ultimately resolved itself into the state of fixed muscular contraction described. He was inclined to the opinion that there was no disease except the fixed contraction of the muscles mentioned, and those he proposed to divide.

ANEURISM OF THE INNOMINATE ARTERY.

Dr. L. A. STIMSON presented a specimen which he believed was unique. It was an aneurism of the innominate artery, in which the tumor solidified perfectly after the simultaneous ligation of the common carotid and subclavian arteries. The specimen was removed from the body of the patient, who, in April, 1880, three months after the operation, was presented to the Society. The tumor at that time, in its reduced diameter, was about one inch, and its height above the clavicle half an inch.¹ From that time the tumor could be felt a little above the clavicle, but remained stationary, and the man worked during the succeeding summer, winter, and spring, although at times he suffered somewhat from a gnawing pain in the clavicle. In July, 1881, the patient complained of dyspnea so much, having phthisis in the right lung, that Dr. Stimson advised him to enter the hospital for treatment. Quebracho gave him marked relief. He remained in the hospital until he died, on the 20th of October, 1881.

The specimen consisted of the arch and the thoracic aorta with the subclavian and carotid arteries on both sides. The aneurismal tumor occupied the anterior wall of the innominate; stopped short of the bifurcation, and practically began at the orifice of the vessel, which was dilated to the extent of an inch and a quarter in diameter. The tumor was conical in shape, extended forwards and to the right about two inches, and its height was a little more than two inches. It was filled perfectly with an adherent laminated clot, which was skinned over, as it were; that is, its free surface was covered by a membrane continuous with the inner wall of the vessel. There was no gap between the clot and the wall of the aneurism, into which blood could penetrate. Upon the posterior or left wall there was a small shallow pouch filled with a clot which was also adherent to the wall of the artery.

The bases of these clots faced one another, were in contact with each other, and between them there could have passed a small quantity of blood, which would make its way into the subclavian artery, which was open. The subclavian artery showed the mark of the ligature in its third division, the ligature itself having entirely disappeared, but the vessel in its first and second portions was open. The carotid was completely filled by a firm adherent clot, from its origin to the bifurcation, both its branches being pervious. And the part of the clot which ceased at the bifurcation showed the same membranous continuation with the inner wall of the vessel already described as present in the aneurism. The carotid did not show the mark of the ligature as did the subclavian, but a transverse linear gap could be felt very plainly at the site of the ligature, and it was evident, he thought, that the inner and middle coats of the vessel were divided at the time the ligature was applied. The left carotid and subclavian were open. The trachea, a short distance above the bifurcation, showed a spot which had somewhat the appearance of a small ulcer, but no distinct ulceration had taken place. The aorta showed a certain amount of atheroma.

The operation was performed in January, 1880, and the patient died of phthisis in October, 1881.

The Society then proceeded to the transaction of miscellaneous business.

¹ See Medical Record, vol. xviii., p. 136.

PROCEEDINGS OF THE BOSTON SOCIETY FOR
MEDICAL IMPROVEMENT.

T. M. ROTCH, M. D., SECRETARY.

NOVEMBER 28, 1881. DR. T. B. CURTIS presided.

PSEUDO-RHEUMATISM.

DR. W. E. BOARDMAN read a paper entitled *A Case of Pseudo-Rheumatism*. Vide page 533 of this journal.

DR. WHITE remarked that the rheumatic pains in this case were no more severe than those occurring with erythema multiforme at times, or in purpura rheumatica. They were not characteristic of the hemorrhagic form of the latter affection. It seemed to him that the cutaneous hemorrhage in the case was remarkably restricted in distribution and slight in the size of the individual manifestations for one of true Werlhoff's disease.

DR. F. C. SHATTUCK remarked that true hemophilia was usually considered to be a disease which develops itself in early life, and would certainly manifest itself in some way before the age attained by Dr. Boardman's patient; he also said that children sometimes outgrow it.

DR. SHATTUCK thought that this case could hardly be one of poisoning by salicylic acid.

DR. ABBOT said that he had had the urine carefully examined in a number of cases where he had given salicylic acid, and that in some of them a slight albuminuria appeared to be caused by it, but in none a permanent injury to the kidney.

RHEUMATIC CHOREA.

DR. ABBOT also gave the details of a case of rheumatic chorea (which he had previously reported to another society), on account of its extreme rarity, the rapid recovery under salicylic treatment, and to give the members an opportunity to examine the handwriting of the patient, who was able to sign her name in a legible and almost handsome hand after fifteen days of treatment, having at the outset been unable to feed herself. The case is printed in full in the JOURNAL for December 1st, page 512.

DR. DENNEY remarked that he had examined a number of cases of chorea to determine whether the disease was hereditary, and had found it hereditary in only two cases, and combined with rheumatism in only one.

DR. MORRILL said that he had found that twenty grains of salicylate of soda given four times daily to patients suffering from sub-acute rheumatism gave considerable relief.

DR. COWLES spoke of the case of a fisherman's boy who had an attack of intercurrent chorea and rheumatism. He first had a severe attack of chorea, and then in a few days the choreic symptoms passed off, and tenderness of the joints and an attack of acute rheumatism appeared; then, as the rheumatism got better, the chorea again developed. The illness lasted six weeks, and ended in recovery.

A MEXICAN SKULL.

DR. WHITNEY exhibited the skull of an Indian, found in a cave in Mexico, showing a stone arrow head lodged in the superior nasal fossa. The skull belongs to the collection of the Peabody Museum of American Archaeology at Cambridge, and was shown by the kind permission of Mr. F. W. Putnam, the curator.

Recent Literature.

A Treatise on Orthopaedic Surgery. By J. WARRINGTON HAWARD. London: Longmans, Green & Co. 1881.

This is in many respects an excellent work. There is an entire absence of self-glorification or dogmatic reasoning from personal experience which not unfrequently disfigure the literature of this branch of surgery. It contains in the main the views of the leading English authorities, in some respects modified by the author's experience. The chapter on rickets is instructive, embracing some matter comparatively new to the general medical reader. That portion describing Dupuytren's contraction of the finger and that on in-growing toe-nail are sensibly written. The chapter on club-foot is well illustrated, but contains little that has not been said before. Diseases of the joints and caries of the spine are purposely omitted from the work, but even after thus limiting the field the author cannot be said to have completely covered it, the book being a striking example of that complacent provincialism which perhaps reaches its highest development among Englishmen. The author attempts to write a treatise, and quotes largely from English writers, but he entirely ignores the excellent work which has been done by Continental surgeons in the last ten years. There is, we believe, no quotation from any recent authority, not English, except a reference to Dr. Sayre, and a mention of Friedleben, as quoted by Dr. Fogge, an Englishman. It is to be hoped that the writer will in the future subscribe to and use the *Index Medicus*, and that before preparing the second edition of his book he will become cognizant of at least Volkmann's report on subtrochanteric osteotomy, Boeckel's experience in osteoclasis and osteotomy, the results of Delore's method in genu valgum, the valuable papers by German surgeons on wedge-shaped resection of the tarsus in club-foot, the Italian hygienic treatment of rickets, and the excellent results obtained by Hurter's operation in valgus of the great toe.

Mr. Haward's work is so well done, as far as it goes, that his readers desire a more complete treatment of the subject.

Favorite Prescriptions of Distinguished Practitioners, with Notes on Treatment. By B. W. PALMER, M. D. New York: Birmingham & Co. 1881.

This compilation of prescriptions will probably prove of value to many practitioners, especially of the kind who prefer to use the clinical experience of others rather than their own therapeutical knowledge. We cannot forbear hazarding the remark that the most skillful physicians are those who build up their prescriptions upon the basis of each case, without reference to the class of diseases to which it belongs. The olden time of dealing out prescriptions, as the card-player does a pack of cards, we hope, is almost obsolete.

—A physician of Cincinnati has been fined \$10 and costs, on complaint of the Board of Health, for failing to report a case of small-pox which he had under treatment for fourteen days.

Medical and Surgical Journal.

THURSDAY, DECEMBER 8, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.

No. 4 PARK STREET, BOSTON, MASS.

PARADOXICAL TEMPERATURES.

AN unusual number of cases of paradoxical temperatures have appeared of late in the English medical journals. Among them we notice three which may serve very well as types of the great majority of these clinical puzzles.

The first of these cases was one which had previously fallen under the observation of Dr. Horatio Donkin, who, in several articles in the *Lancet*, has analyzed a large number of instances of excessively high temperatures, and was reported by Dr. MacKenzie at the London Clinical Society.

The patient, a woman, and a confirmed opium-taker, who had had much experience of hospitals, was admitted to the London Hospital for pain and swelling of the abdomen; at this time the temperature was normal, and nothing especially noticeable was recorded concerning the case for nearly three months, when, after a "slight rigor" in the morning, a temperature of 109.2° F. was observed at night with a normal pulse. With some vomiting and "pain in the head," the patient furnished from this date, January 13th, onward to January 27th, temperatures varying at different hours and on different days from normal to 120.8° F.; from the latter date for a week there were no high temperatures, when, to cut a long story short, the previous symptoms reappeared accompanied by the thermometrical vagaries, and continued intermittently for a number of weeks. On no occasion when the patient was strictly watched or the thermometer held in the axilla were excessively high temperatures observed. In reporting this case to the Clinical Society Dr. MacKenzie expressed his decided belief that the excessively high temperatures were fictitious, and for very excellent reasons, as our brief abstract of the case indicates, though the patient stoutly denied illegitimate complicity with the temperatures. She, however, confessed producing them with the aid of poultices and hot bottles in season to enable a postscript to be added to the report of the case as appearing in the *Times and Gazette* of November 5th. The confession was sorely needed in this instance to establish the deceit, but it enables us to refer to the case as illustrative of one class of these cases of paradoxical temperatures, namely, that in which there is deception with subsequent discovery of the method.

Another instance reported by Dr. Mahomed¹ at the same meeting of the Clinical Society is a good

¹ *Lancet*, November 5, 1881.

example of the paradoxical temperature evidently spurious, but the method of producing which remains undiscovered.

A young woman, somewhat hysterical, suffering from phthisis affecting one lung, was admitted to Guy's Hospital September 30th, and was under observation for eighteen months, when she died from scarlatina. It was not her first acquaintance with hospital life. For the first three months that her temperature was regularly taken morning and evening it varied from normal to 102° or 103° F.; during the month of June it gradually assumed a higher range, varying from about 101° to 104° or 104.8° F. It first became phenomenal July 23d, registering 106.4° F.; two days afterwards, in the evening, it marked 107.4° F., and two hours later 110.8° F. During July and August the temperature only rose five times above 105° F., and at each of these the index was lodged in the end of the thermometer. Early in September the patient, probably tempted by being under the supervision of a new clinical clerk, and by the general interest which her case began to excite, indulged herself most recklessly in strange temperatures. Thermometers placed in various parts of the body simultaneously would give various readings at the same moment, and two or more successive observations on one part would give variations from normal up to 120° F. On one occasion three thermometers were used at the same time in the presence of a physician and several students, one being placed in the mouth and one in each axilla; they were not held in. On removal on one side the thermometer registered about 102° F., in the mouth 107° F., and on the other side 114° F. (these numbers are not exact). The thermometers were then all changed, the highest temperature being now recorded in the opposite axilla, and that in the mouth was about 101° F. They were again changed with fresh results. It appeared that the only check to the position of the index was the length of scale of the thermometer, it being frequently, and at this time, indeed, usually lodged in the small expansion of the tube at the top. Some thermometers were now procured from Mr. Hawksley, which had a scale for several hundred degrees, but these were non-registering, and by means of them only ordinary temperatures were obtained. The house-physician obtained a self-registering clinical thermometer with a scale reaching to 130° F., and with this an indication of 128° F. was given on October 15th. She appears to have felt that she had gone too far on this occasion, for comparatively few high temperatures were recorded after this, but about thirteen times during the next five months. It was especially noteworthy in this case that a high temperature was never indicated by a non-registering thermometer, though they were often used. She frequently objected to the use of these, which were of larger size than the ordinary clinical thermometers, calling them "horse thermometers." The loan of some surface thermometers were obtained, which were strapped on the chest wall, but they gave nothing but ordinary results, although extravagant temperatures had been recorded immediately before. The high records could be ob-

tained at any time in the day, and appeared entirely under the control of the patient, who would frequently state beforehand that the temperature would not be high. The high temperatures were not accompanied by any corresponding increase of pulse-rate or respiration, though afterwards her breathing was sometimes noticeably hurried, as if from exertion. No high temperature was ever obtained by Dr. Mahomed when he kept his hand on the arm of the patient during the time the thermometer was in the axilla. No increase of temperature of the skin or in the axilla could be detected by the touch during or immediately after the record of an extraordinary temperature, nor was the bulb of the thermometer hot at the time of removal, as it would necessarily have been had the temperature of the body been really high. . . .

"Although during June, July, and August her temperatures had been progressively increasing and always high, yet her body weight, which was one hundred and fifteen pounds on December 9, 1879, had only decreased to one hundred and twelve pounds on September 9, 1880, being a loss of only three pounds in nine months. During the next three months she lost ten pounds, her weight falling to one hundred and two pounds by November 30th, but her physical signs of disease had been steadily increasing throughout this period."

Though frequently charged with it the patient generally denied any deception, but she often smiled, and sometimes said, "Why don't you find it out?" The method employed by her was not discovered, although she was evidently much more closely watched than the previous case, and she ultimately died from an attack of scarlet fever.

The third case to which we shall refer may be fairly regarded as a genuine case of paradoxical temperature, and as sufficiently illustrative of those not very uncommon instances of flushes or flashes of heat accompanied by a more or less phenomenal and more or less evanescent increase of temperature. The patient, though, strange to say, a young man, is described by Dr. Puzey, of Liverpool, who reports his case,¹ as of such an extremely excitable and emotional temperament that the term hysterical would have been perfectly applicable to him. He was admitted to the hospital on account of old-standing disease of the knee-joint, for which he underwent excision. The case progressed very well without anything especially remarkable about the temperature until about three weeks after admission, when it rose from 99.8° F. the evening of March 9th to 102° F. the evening of the 10th, and to 109° F. at seven A. M. March 11th, from which point it declined to 103.2° F. at eleven A. M., and had returned to 99.8° F. that evening. The temperature remained pretty steady until March 20th, when the following changes were observed: At eight P. M. 106° F.; at about one A. M., the 21st, 105° F.; a few hours later 102° F.; in the evening 100.6° F. At this time there was no apparent constitutional disturbance, the wound was looking well, and free from redness or tension.

In commenting on his case the reporter says: "The temperature, which certainly had been normal before the operation, never touched the normal point after, and six months after was still higher than the standard. The markings were often lower at night than in the morning, and the pulse and respiration frequently bore no relation to the temperature. . . . When these high temperatures were noticed, he was invariably flushed and apparently excited; the hands and tongue tremulous; and any attempt at examining the affected limb caused loud exclamations of pain, sobbing, and shedding of tears, afterwards followed by just as unreasonable laughter. I should add that the man was carefully watched to see that no tricks were played with the thermometer, such as friction of the bulb in order to raise the temperature; and I ascertained practically myself that no elevation of the mercury could be caused by rolling the bulb in the mouth against the tongue."

We have noticed these three cases at some little length, not so much because they are very rare, as because they are typical of what does now and then occur, or is liable to occur in hospital, or even in private, practice. There are other rare instances of very elevated temperature, and continuously so for days or even a week, such as that reported by Mr. J. W. Teale,² the explanation of which, perhaps, still remains to be given.

Sellerbeek states that it is easy to raise the mercury to 108° F. in three minutes by rapidly rotating the bulb between the bare skin of the arm and the thorax, and Mahomed that it is easy to send the index of an ordinary clinical thermometer up to the top, in from ten to fifteen seconds, by rubbing it between the slightly moistened finger and thumb, exerting at the same time considerable pressure on the bulb. The same result, he says, can be obtained by enveloping the bulb of the thermometer in several folds of silk and placing it in the mouth; then inspiring by the nose and expiring by the mouth; this no doubt is produced by the evolution of the latent heat of the watery vapor of the breath, as it becomes condensed upon the silk.

In common with others we have not been able to verify the above statements, though unwilling to deny that some may be more expert. We are inclined to adopt the conclusions of a short report³ to the Suffolk District Medical Society on animal temperature, in which the writer states his belief: (1) that the range of animal temperature which is not incompatible with human life is much larger than has, until very lately, been supposed, extending in all probability at least from 76° to 122° F., or 46 degrees; and (2) that very remarkable and sudden oscillations of temperature, covering many degrees, sometimes occur, which cannot at present be satisfactorily explained.

— Dr. Louis Elsborg, of New York, has been appointed Professor of Laryngology and Diseases of the Throat, in the Dartmouth Medical College.

THE HOSPITAL SATURDAY AND SUNDAY ASSOCIATION OF NEW YORK.

THE Hospital Saturday and Sunday Association of New York has just issued its annual tabulated statement, showing the work and resources of each of the hospitals connected with the Association, for the year ending September 30, 1881, and this is accompanied by its annual appeal to charitably disposed individuals, and to the various churches. From the statement we learn that of 8688 patients treated during the year in the 20 hospitals of the Association, 6698 were free and of the class to whom the contributions solicited by the society are applied. During the year 248,680 days of hospital care have been given to these free patients, in 17 hospitals, and this, at the average cost of \$1.15 per day, shows an expenditure of \$285,982 by these institutions in the free care of the sick. Of this large sum but \$88,735.05 was received from the invested funds of the hospitals, and for the balance they are dependent upon the yearly gifts of the benevolent and such appropriations as are made by the city. The hospitals represented in the Association treat nearly all the diseases to which the human race is subject. In eight of them cases of accident and every kind of non-contagious and acute disease are treated; four are hospitals for diseases of women and children, two for the ruptured and crippled, four for diseases of the throat, ear, and eye, and three are devoted to the cases of incurables. They all receive patients of every age, nativity, and creed, so that the charity represented by the Saturday and Sunday Association is large enough to embrace every case of real need which is brought to the attention of the society, its capacity for effective benevolent work being limited only by the amount of funds at its disposal. A new feature of the work this year is the establishment of auxiliary associations, which have been formed in some of the various business pursuits under a common constitution and by-laws. The hospitals forming the Association will be asked to agree to receive any sick person nominated by the designated officers of these auxiliaries as free patients under the following conditions: Every general hospital, and the hospitals for women and incurables, to take patients thus nominated for so long as they may need hospital treatment, at the rate of one day's care for every dollar contributed by the auxiliary which nominated them; the hospitals for children, one day's care for every 75 cents thus contributed; and the hospitals for the treatment of the throat, eye, and ear, one day's care for every \$1.25 thus contributed. The total collection for this work in 1879 was \$26 155.07, and for 1880, \$44,371.97; but these large sums fall far short of the actual needs of the hospitals composing the Association.

Hospital Sunday this year, in New York, is fixed for the 25th of December, and the day preceding is Hospital Saturday. Christmas Eve and Christmas Day are peculiarly appropriate occasions for soliciting contributions to a charity of this description. Those who are well and in comfortable circumstances can in no way contribute to their own enjoyment more than by the consciousness of alleviating somewhat the

trials of those who are sick and miserable. The Association is certainly justified in believing that the good days will multiply the good deeds and enable it to carry out generously its plans for increased usefulness.

FIGURES ABOUT THE INDEX MEDICUS.

WE took occasion, not long ago, to take exception to what seemed to us to be a very injudicious method of advocating the claims of the *Index Medicus* to support on the part of the *Philadelphia Medical Times*. Because the *Times* was ignorant of the contributions of other cities it supposed nothing was done in them. The correctness of our view of the case is borne out by a letter of the publisher of the *Index* addressed to the editor of the *Philadelphia Times* and published in its last issue. We feel justified in reproducing a portion of it:—

“DEAR SIR.—Allow the publisher of the *Index Medicus* to thank you, on behalf of that publication, for your earnest and timely words in the *Medical Times* of November 5th; but, lest some of your remarks may be misinterpreted, allow him also to state, in justice to those concerned, that the reproach of ‘has done nothing’ cannot properly apply to the cities of New York and Boston. It is true your remark only refers to the work of the organizations, in which Philadelphia has so prominently taken the lead. But, while New York and Boston have not yet succeeded in carrying out the Philadelphia plan of co-operation, it should not be overlooked that (a fact of which you evidently were not aware) the *individual* support in both cities has been proportionately more than that of any other place. Boston in particular has distinguished itself by a number of liberal private contributions. The following is an approximate percentage of support, representing subscriptions, contributions, and appropriations:—

United States (exclusive of other mention, as specified below)	27½
New York city	22½
Boston	16
Philadelphia	12½
Government departments	11½
Foreign countries	10
	100

“This schedule shows that (Philadelphia and the Government departments excepted) Boston and New York alone contribute more than all the rest of the world.”

We have no desire to pride ourselves on the matter. We hope the contributions will continue to be freely given so long as the *Index* needs support, and we know of no more honorable way for the societies of different cities to afford each other mutual aid than by uniting in the support of this valuable *Index*.

MEDICAL NOTES.

—An out-patient department has been established at the Boston Lying-In Hospital. Hereafter medical attendance will be furnished at their homes to all women who reside within the limits of the city proper, and who are unable to pay for such services.

Miscellaneous.

ANNUAL MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION AT SAVANNAH.

FIRST DAY'S PROCEEDINGS.

THE ninth annual meeting of the American Public Health Association began at Savannah on Tuesday, November 29th. Among those present were Drs. H. P. Walcott, S. H. Durgin, Azel Ames Jr., and B. Joy Jeffries from Massachusetts; and Dr. Stephen Smith and Professor J. L. Cabell of the National Board of Health. After the formal exercises of the opening and the election of new members, a communication by Dr. Ames, recommending the establishment of a National Museum of Hygiene at Washington, was followed by the offer of the free use of the one already founded by the Surgeon-General of the Navy. Among other communications were those advising the abolition of governmental regulation of prostitution, and that the Society should obtain charters in the various States where it has members.

The first regular paper of the day was by DR. EZRA W. HUNT, of New Jersey, on

THE CONTAGIOUS DISEASES OF DOMESTIC ANIMALS.

Beginning with a generalization of the importance of the study of comparative physiology and pathology, and the direct benefit accruing to man from a more accurate knowledge of the morbid processes in animals, the writer passed to the consideration of the separate diseases found among them. Contagious pleuro-pneumonia has as yet produced no specific disease in man, its importance depending upon the production of an inferior quality of meat. It was otherwise, however, with splenic fever and other forms of anthracoid disease, which are directly and virulently contagious. Hog cholera derives its interest, not only from the immense pecuniary loss it entails, but from the fact that the pork when eaten is capable of causing sickness. In the remarks on trichinosis it was shown that, relative to the vast number of swine produced in this country, the per cent. of those infected falls far below what is found abroad, and that, though there is a reaction against the stringent legislation regarding American pork, still, until a regular governmental system of examinations is instituted, our exports must necessarily be limited. The paper closed with practical suggestions regarding the inspection of all meats.

DR. JOSEPH R. SMITH, U. S. A., offered the next paper on

DISEASE AMONG TEXAS CATTLE.

From his observations he concluded that Texas cattle in their prairie pastures are singularly free from disease; that the weight of the spleen is an element of value in determining diseased conditions only in comparison with the weight of the whole animal and its age. As the result of experiments upon the temperature of cattle it appeared that the normal range was four to five degrees higher than in man.

TRICHINA SPIRALIS.

A report of the New Orleans Sanitary Auxiliary Association upon the Examination of Hogs at the New Orleans Abattoirs during the summer of 1881 followed. Of the fifty-four hundred hogs examined, twenty-two were found infected with trichinae. As a result of

study upon these it appeared that corn-fed hogs alone were affected and that Southern swine were free from the disease.

The fourth paper, by DR. JOHN PATRIDGE, of Indiana, on *Trichina Spiralis*, commenced with remarks on parasites in general as found in man and in animals, noticing their method of development after ingestion, and the varying larva produced by the same ova in different animals. The trichina spiralis as found in man was then considered, a brief pathological sketch being prefaced to a clear clinical history of the disease. The case of a nursing child, infected through its mother's milk, was instanced as showing the wide distribution of the parasite when once in the body.

A paper by DR. F. S. BILLINGS of Boston on *Trichina Spiralis* in American and German Hogs killed at San Antonio, Texas, read by title only, closed the morning session.

The first paper of the afternoon was by DR. S. S. HERRICK, of New Orleans, on

THE COMPARATIVE VITAL MOVEMENT OF THE WHITE AND COLORED RACES IN THE UNITED STATES.

He showed that the rate of mortality was much greater among the colored, especially during the first five years of life; that there was a greater liability to consumption and acute lung disease, while especial immunity was enjoyed from cancerous diseases, delirium tremens, and suicides. Much of the increased mortality was due to inferior medical and hygienic attention. He also proved that there is a steady increase in the colored population, and that the African race is not dying out. An interesting fact was the vital disturbance in the colored gain during the decade 1860-70, being 9.9 per cent. against 22.1 per cent. in 1850-60, and 34.8 in 1870-80. From the almost absolute immunity from competition in their occupations, and the absence of overcrowding, he considered there was destined to be a constant numerical increase, but the same factors will prevent any corresponding intellectual improvement, because of the lack of incentives to other and higher industries. An interesting discussion on the probable future of the colored race in America followed.

PROF. JOHN L. CAMPBELL, of Indiana, next read a paper upon The Kankakee, a Sanitary Problem of Indiana, showing how a large tract of waste and malarial land could be made productive and healthful by securing drainage by the Kankakee, and suggesting various methods for accomplishing this result. The two remaining papers, The Disposal of our Dead, by DR. W. H. CURTIS, of Illinois, and The Relation of Alimentation to Infantile Development and Disease, by DR. T. C. DENCAN, were read by their titles only.

At the evening session a formal welcome was extended the Association by CAPTAIN MERCER, representing the city, who alluded to the increasing value of the results of these meetings. He was followed by DR. R. J. MUNN, of the Georgia State Medical Society, who dwelt especially upon the opposition with which advanced sanitary measures were received by the people, and the importance of the work the Association had undertaken.

ANNUAL ADDRESS.

The annual address by DR. C. B. WHITE, the president of the Association, followed. Giving the names of the deceased members, he spoke warmly of the services they had rendered, and suggested the ap-

pointment of a committee to prepare a suitable memorial. Among the replies, he continued, to a circular asking for subjects for investigation, was the suggestion whether there was such a thing as sanitary science, and this question formed the general theme of the address. The speaker said that at all times there had been individual observers and collectors of vital statistics but never any uniformity either of observation or arrangement, and attributed this to lack of proper training in scientific investigation even among scholars, a defect, which as scientific methods are made more familiar, and scientific men are better known, will be lessened generation after generation, although at present we are almost at the beginning of knowledge in this particular. He deprecated the hasty generalizations and unfair, incomplete theories constantly thrust forward and as constantly overthrown, thus causing distrust to those not conversant enough with science to discriminate judiciously. He alluded to those who, living in opposition to all known hygienic rules, continue strong and well, as possessing some hitherto undefined peculiarities beyond their fellows, enabling them to defy all laws of health. The individual he regarded as the offspring of race hygiene, and race hygiene as the object of sanitary science. He thought the point had now been reached when expert work was necessary for progress, and that the efforts of amateurs of unbounded zeal and equal ignorance required trained guides, which the States must furnish. That over these there should be a still higher power, of necessity national, which should systematize and bring into a complete whole the works of individuals, and with other countries form an international commission. Regarding the proper education of the people as most essential for the acceptance of whatever good sanitarians may discover, he suggested suitable study and preparation, beginning with early childhood, and not limited to scientific schools alone. The address closed with the prophecy that as population was increased by race hygiene, so sanitary engineering would develop nature's resources, and the struggles for existence would be lessened rather than increased.

A committee was appointed to prepare a suitable memorial of the deceased members, and, after accepting an invitation to the members to attend a reception at the residence of Dr. Falligant, the meeting adjourned.
(To be continued.)

LETTER FROM LONDON.

THE PROSECUTION OR PERSECUTION OF PROFESSOR DAVID FERRIER, F. R. S., M. D., BY THE ANTI-VIVISECTIONISTS.

MR. EDITOR.—A fortnight since a summons was granted at the Bow Street Police Court, returnable to-day, against this world-famed physiologist and physician. It is almost needless to say that this course was adopted at the instigation, if not indeed by the very hands, of those numerous, perhaps soft-hearted, little-thinking and misguided persons who support the various associations having for their ultimate purpose the total suppression of scientific research by experiment upon living animals other than human. At two o'clock this afternoon Sir James Ingham, the senior magistrate for this metropolis, sat to hear the case. The precincts of the court bore an altogether unusual appearance. Its approach, which is most often crowded by an illit-

erate gathering whose features bear undeniable testimony to their drunken and criminal habits, was surrounded by an enthusiastic, educated, and surging assembly numbering many hundreds, among whom the experienced eye could recognize many of the chief of the leaders of medicine, surgery, and science in this country. Considering the amount of feeling that was evidenced by such an assemblage, and that its great majority were medical, and therefore physiological, students, all of whom must have entertained the highest opinion of the defendant, it is highly satisfactory to be able to report that the ever over-zealous police deemed it advisable to arrest only a single individual, who, happening to be in the front of the clamoring and ardent crowd, became the scapegoat of the occasion. The interior of the court presented a no less unusual aspect than its exterior. Seven chairs on either side of the magistrate gave accommodation to a favored few, among whom there were five ladies, besides Dr. Hughlings Jackson, Professor Lister, Curnow, and Bell. I was informed, though unable to see from my position, that the Baroness Burdett-Coutts was in the court, and this I regret to say is only too probable, for in this matter her kindness of heart has conspicuously eclipsed that calm judgment which should have led her to accept the unanimous verdict of her late guests, who, during the recent International Medical Congress, so unhesitatingly declared themselves opposed to the whole principle of the anti-vivisection legislation in this country. The audience in court included numerous distinguished members of our profession, and I recognized Michael Foster, Gerald Yeo, Burdon-Sanderson, Klein, and others, especially the defendant's colleagues at King's College. The summons was taken out under the vivisection act, and charged him with having, on the 4th day of August, and on divers other days thereafter, performed experiments calculated to give pain to two monkeys, and in violation of the restrictions imposed by the above acts. Mr. Waddy, Q. C., Mr. Besley, and the Hon. Bernard Coleridge appeared on behalf of the Victoria Street Society for the Protection of Animals from Vivisection, by whom the proceedings were instituted; Mr. Gully, Q. C., and Mr. Houghton appeared for the defense.

Sir James Ingham, addressing the defendant, intimated that, by the provisions of the Act, he could be tried by a jury, and asked whether he would prefer that course, or have the case dealt with summarily.

Mr. Gully decided upon the adoption of the latter course.

Mr. Waddy then addressed the magistrate, and said that, though he had stated the case a fortnight ago, he proposed to reopen the facts briefly.

Mr. Waddy's opening address could have been judged brief by none other than himself, for to all who heard it it was the prosiest and poorest twaddle that could have been tolerated in the support of the feeblest case. This counsel for the prosecution repeatedly endeavored to gull the magistrate into the belief that the vivisection act should be interpreted for the persecution of individuals who were utterly unimplicated in the infliction of pain upon animals. The magistrate repeatedly indicated his own view that a prosecution which failed to attach to the defendant the infliction of pain to some animal could not be maintained under the act. However, despite all consideration for the time of those present, and the feelings of the numerous patients who must have been anxiously and painfully awaiting the

visits of their respective medical men, Mr. Waddy expended over an hour in urging that under the fourth section of the act any person would be guilty of an infringement of the act if such person made any observations, no matter how painless, at any time upon any animal, prior to its death but subsequently to its having been experimented upon. Indeed, the well-concealed ingenuity of this prosy counsel was at one time apparent in the suggestion that it would be possible for animals to be sent abroad, there to be mutilated beyond the jurisdiction of the vivisection acts, and then brought back to be observed here. The first witness called was an honorary secretary of the Physiological Section of the International Medical Congress. This witness was examined by the prosecution with a view to authenticating a report of the proceedings of his section as published in the *British Medical Journal* for October 8th. Instead of so doing the witness stated that he was excessively and variously occupied during the sitting of the Congress; that some days later he was applied to for some matter which might furnish a foundation for a notice in the *British Medical Journal*; that he then dictated such particulars as then occurred to his memory; that a short-hand writer, of whom he knew nothing, professed to take down such reminiscences as were dictated, and the witness neither saw nor heard anything more of the seven or eight columns which it was endeavored to attribute to his pen until they were published to the world some two months later. The witness made it evident that the council of the Physiological Section of the International Medical Congress had taken pains to avoid involving themselves, through the official business of their section, in any controversy on the so-called vivisection question.

The next witness called by the prosecution was professor Michael Foster, F. R. S., president of the physiological section at the Congress; whose titles alone more than bewildered the "Hon." junior counsel for the defense. Michael Foster corroborated all the last witness's evidence concerning the unofficial participation of his section in any controversial matter under the vivisection act. He very clearly stated that on August 4th Professor Goltz described certain phenomena as resulting from the removal of the surface of the brain of animals. This professor quoted numerous experiments, and mentioned having brought over a dog on whom he had operated in support of his view that special motor phenomena could not be rightly ascribed to definitely localized portions of the surface of the brain. Professor Ferrier then expressed views antagonistic to those quoted by Professor Goltz. The former supported his views by reference to numerous experiments upon the brains of monkeys. Such experiments might be for the purposes of the trial divided into two sets, old experiments and more recent experiments; the former had nothing to do with this act, the latter had been performed antiseptically. Here Michael Foster, in compliance with the request of the bench, most pithily defined in non-technical language antiseptic surgery as he understood it. He said that unofficially, purposely unofficially, though president of the physiological section, he had, in conjunction with probably a hundred other physiologists, including the most eminent, arranged on the 4th of August to pay a visit to the physiological laboratory, presided over by Professor Gerald Yeo, at King's College. That he had there seen the dog of Professor Goltz, and two

monkeys which had been referred to by Professor Ferrier, when speaking of the observations he had made upon monkeys which had been operated upon antiseptically. The witness described how the visitors to the laboratory witnessed the demonstration of the phenomena displayed by the dog and monkeys, which had been operated upon many months before. He testified to the defendant's conduct with the monkeys having on that occasion been confined to demonstrating the deafness of one monkey, by firing a toy pistol in the neighborhood of such monkey and another, when the latter started while the former paid no heed to the report of the explosion. While in the case of the second monkey, it was alleged to demonstrate its partial hemiplegia by perambulating about the floor and taking a biscuit from Professor Ferrier's hand. The witness said the observations had special reference to motor functions, that no galvanic battery was used, that he did not remember a monkey being pinched, but if it were pinched on that occasion the pinching would have been slight and solely for the purpose of eliciting the comparative sensibility of the two sides of the monkey. He had known for a very long period of the experiments on these monkeys, such knowledge having been the common property of physiologists; he knew that Professor Yeo had carried out the operations on these monkeys, and that such operations had been performed under anaesthetics. The proposition to kill the dog and one of the monkeys had been the result of the consensus of opinion expressed by the physiological visitors to Professor Yeo's laboratory, and this proposition was not put into effect with Professor Yeo's consent. The post-mortem examination of these animals had been assigned by the Congress to four eminent histologists, including Schaefer, Klein, and Gowers.

After this witness's examination the case would have closed but for the obstinacy of the prosecuting counsel, who would under any other circumstances have deserved pity, on account of the feebleness of the cause they represented. The editor of the *Lancet* was the next and last witness put in the box; he produced the manuscript with which he had been furnished by Professor Gamgee. This last-named gentleman, who hails from Owen's College, Manchester, was not in court, and on this score an adjournment was demanded by the prosecution. The magistrate said he could only grant an adjournment on the condition that the defendant's reasonable costs in consequence thereof were guaranteed by the prosecution. The prosecuting counsel, whose conduct of this feeble case was from the first as feeble as it was obstinate, directly insinuated that the adjournment was necessary in consequence of the great opposition which the medical profession had, during the last fortnight, placed in the way of the preparation of the case against the defendant. However, the defendant's counsel, whose conduct of the case was as able as it was brief, elicited the fact that the prosecution had made no effort to ascertain the authorship of the *Lancet* report; though, since the summons was taken out, the defense had ascertained who was the author of the matter furnished for the *Lancet* report. Further, that Professor Gamgee asserted that he could in no way vouch for the accuracy of his notes otherwise than so far as they referred strictly to the scientific and non-legal general bearing of what took place in reference to, or in connection with, the discussion opened by Goltz.

In desperation, the prosecuting counsel, while withdrawing his application for an adjournment, claimed that though Professor Yeo made the first and painful part of the experiment, Ferrier was guilty of an infringement of the act in having countenanced the subsequent keeping alive of the grievously injured animals.

The magistrate then dismissed with costs the summons against Dr. Ferrier, whom he considered implicated in any breach of the act of parliament, which he did not believe could be stretched to involve, in a criminal conviction, any person or persons who, subsequently to the performance, by some other party, of a cruel (and correcting himself he said painful) operative experiment on any animal, simply made observations during the remainder of its life.

This termination of the case barely afforded the defending counsel an opportunity of explaining much, which, but for his brief remarks, might have left many of the outsiders to believe that the defense was trumped up, and that the failure of the prosecution was solely attributable, or indeed at all attributable, to the blundering incapacity of the junior counsel, who attempted to examine the few witnesses, who it was vainly hoped might let drop some expression in justification of this prosecution, which it is difficult to speak of in measured terms.

Mr. Gully stated that the monkeys had been operated upon under anaesthetics by Professor Yeo, who held a license under the said act. That the experiments had been carried on in Professor Yeo's laboratory, from which the monkeys had not been removed during life. That keeping them alive subsequently to a cessation of the effect of the anaesthetic under which they were operated upon, had been duly sanctioned in accordance with the act, and that in every respect Professor Yeo, who was alone responsible for the experiment upon the monkeys, had conformed to the requirements of the act.

LONDON, November 17, 1881.

MALARIA IN NEW ENGLAND.

MR. EDITOR, — In response to your inquiries about indigenous malaria in New England, the following has some interest: A little girl, seven and a half years of age, who was born in Fall River, and had never been out of New England, after ailing a few days, had a chill September 15th. She was well on the 16th, had a chill on the 17th, was well on the 18th, had a chill on the 19th, when the administration of quinine every four hours was begun. Since that time she has been well. The chills were very severe, almost congestive. There is not a doubt in my mind as to the nature of the case, though the patient, a bright little girl, was called upon to do a good deal, and her general health had suffered somewhat before the chills occurred. She lives on a high, sandy plateau, with a mud-pond covering an acre about one thousand feet from the house. I had another similar case, though that patient had been out of New England. Yours truly, W.

PAULICKET, R. L., September, 1881.

MR. EDITOR, — In response to your inquiry for cases of malarial fever arising in this vicinity, the following may be of interest: —

August 7th I was called to see Paul B., 12 years of age, living near Fresh Pond, Cambridge. He had been unwell for three weeks, and for the last week had had a chill at about noon of each day, followed by fe-

ver and sweating. I ordered quinine, one dose at night and one at 8 o'clock, A. M. He did not have another chill, and recovery was perfect. This boy had never been farther away than Newton.

I have had several other cases, but they were not so well marked, though they yielded promptly to quinine. I will report the following: —

In July, 1880, I was called to a boy living on Spruce Street, Cambridge. For ten days he had had an attack of colic and diarrhoea at 4 o'clock, P. M. After about an hour he would have considerable perspiration and then would be very well till the next attack. He had never been out of Cambridge. This case yielded at once to quinine. Yours truly, H. P. M.

WEST SOMERVILLE, October, 1881.

CORRECTION: SPONGILLA FLUVIATILIS.

OWING to an unfortunate transposition at the press, of several sentences in the remarks on the fresh-water sponge (*Spongilla Fluvialis*) which appeared in the last issue of the JOURNAL, page 527, the true meaning was somewhat obscured and a false impression conveyed on one or two points. We therefore reproduce the sentences on page 528, the first column, which were affected by the error: —

The skeleton which supports the animal is made of a net of siliceous spiculae. These project on all sides, and, being covered by the animal substance, give a spiny appearance to the sponge when partially dried. Alive it is quite smooth externally.

Probably on account of these spiculae of flinty matter no animal is known to feed on spicular sponges, except a mollusc, the body of which is found filled with the spines. They probably pass through his tissues without injuring him, as a needle may through the human flesh.

While alive the sponge is of a greenish color, due, probably, as in plants, to the effect of light, as those parts of similar animals which remain under stones in the dark are of a light brownish hue. This sponge lives in fresh-water ponds; clean ponds cannot be said to be free from it. We might expect it to prosper in ponds with dirty bottoms, and occasionally, as in Farm Pond, to multiply excessively, die, decay, and impregnate the water with the stench of decaying animal matter.

A pond with a clean bottom, though not completely free from it, does not probably offer the conditions necessary for its excessive growth.

This sponge does not probably live in the water pipes. The current and the pressure of the water would probably interfere with its growth. What has been found on the interior of water conduits, and has been mistaken for the seed bodies of the sponge, are probably the seed bodies of some kind of bryozoa. These are the moss animals, so called on account of their resemblance to small bush-like and creeping growths, and which are found attached to solid objects lying on the bottom, or floating in the water.

In our water supply this sponge has not yet been found out of Farm Pond, but it has not been carefully looked for anywhere. It is not impossible that it exists in Sudbury River Basin No. 2, where Professor Remsen finds more than a due allowance of nitrogenous matter; and one of the first things to do should be to ascertain if it be there or not, if it is not already too late in the year to find it.

THE LONDON SANITARY PROTECTION ASSOCIATION.

In commenting upon the first formal meeting of this Association, held lately, the *Lancet* says Professor Huxley, with his usual happy phraseology, described the Association "as a coöperative store for the supply of good advice." He was less happy in his description of the objects of the Association, and of the position it holds in the sanitary advancement of the public; and an obvious lapse of memory was evident when he remarked that "disagreeable as the old cesspool system was, it was attended with very little danger compared with that which waited upon the water-carriage system if that system was imperfect." When, moreover, he stated that there were two ways of meeting the dangers which the Association sought to cope with—namely, one by the action of the Government, the other by promoting an intelligent knowledge of the

evils to be removed, it was insufficient to point out that governmental action was impracticable, as involving an intrusion in the affairs of private life which would be intolerable, and moreover, on account of the expense. By recent statutes communities have, or may have, large powers of providing for themselves all essential sanitary requisites. The extent to which such provision has been made must depend on the level or intelligence in sanitary matters to which the community has reached. This as yet falls far short of the level which the legislature contemplated, and in proportion as associations such as the Protection Association cultivate a higher knowledge and better appreciation of sanitary matters as relates to dwellings among individual householders, in proportion they will reach a matter which is beyond the power of the legislature, and develop that knowledge among the masses which must underlie all sound local self-government, and upon which the efficiency of sanitary legislation depends.

Deaths reported 2722: 983 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 727, consumption 412, lung diseases 308, diphtheria and croup 271, typhoid fever 102, diarrhoeal diseases 94, small-pox 80, scarlet fever 78, malarial fevers 48, measles 13, whooping-cough 12, erysipelas 11, cerebro-spinal meningitis 10, puerperal fever eight. From small-pox, Chicago 28, Pittsburgh 20, Philadelphia 16, New York eight, Cincinnati five, Baltimore three. From scarlet fever, New York 36, Brooklyn 16, Buffalo five, St. Louis and Baltimore four, Chicago three, Philadelphia, Dis-

trict of Columbia, Pittsburgh, and Milwaukee two, Cincinnati and Worcester one. From malarial fevers, New York 11, St. Louis nine, Brooklyn and New Orleans seven, District of Columbia five, Philadelphia four, Buffalo two, Chicago, Baltimore, and Charleston one. From measles, New York eight, Chicago two, Philadelphia, St. Louis, and Milwaukee one. From whooping-cough, New York and Chicago four, Baltimore two, Brooklyn and Boston one. From erysipelas, Chicago three, Boston two, New York, Philadelphia, Brooklyn, Baltimore, Buffalo, and Milwaukee one. From cerebro-spinal meningitis, New York five, Chicago, Pittsburgh, New Haven, Gloucester, and Wal-

than one. From *puerperal fever*, Brooklyn three, Cambridge two, Chicago, St. Louis, and Buffalo one.

Eight cases of small-pox were in Brooklyn, two in Boston, four in St. Louis, 10 in Cincinnati, two in District of Columbia, 61 in Pittsburgh, and 14 in Holyoke; diphtheria 38, typhoid fever 18, scarlet fever two, in Boston; diphtheria 12, scarlet fever 10, in Milwaukee.

In 37 cities and towns of Massachusetts, with a population of 1,031,439 (population of the State 1,783,086), the total death-rate for the week was 18.25 against 18.48 and 18.72 for the previous two weeks.

The meteorological record for the week ending November 26th, in Boston, was as follows:—

DR. DANIEL HARWOOD.

At the fourteenth annual meeting of the American Academy of Dental Science, held in Boston, October 26, 1881, the following resolutions were unanimously adopted:—

Resolved, That the American Academy of Dental Science have received with sincere sorrow the intelligence of the death of their late associate Dr. Daniel Harwood, one of the oldest honorary members and formerly President of this Society. He departed this life on Saturday, October 2, 1881, in the eighty-first year of his age.

Resolved, That by the decease of Dr. Harwood, whose professional career extended through a period of more than half a century, we add another honored and illustrious name to the catalogue of distinguished members of the dental profession who have finished their earthly labors and passed on to the land of rest and immortality. He was one of the first in our country to take a high stand in the practice of his profession. He was unmistakably a man of energy and talent, courage and fidelity. The designs of his operations have always evinced good, strong practical common sense, and their execution has demonstrated an honest determination to do the best for his patients possible.

Resolved, That the example of Dr. Harwood has done much to stimulate young men to put forth their best exertions, and few indeed will leave behind them so good a record as he. Although his departure will be deeply felt, yet we should be thankful that he was spared so long, and that in his declining years he had the satisfaction of seeing that his profession was advancing nearer the ideal that he and others reared for it in other days.

Resolved, That a copy of these resolutions be sent to the family of Dr. Harwood as an expression of our sympathy in their great bereavement.

Resolved, That a copy be entered upon the records of the Academy and also sent to the dental and medical journals for circulation.

CASES ILLUSTRATING RARE COMPLICATIONS AND SEQUELE OF TYPHOID FEVER.

A CLINICAL LECTURE DELIVERED AT THE PENNSYLVANIA HOSPITAL, NOVEMBER 19, 1881.

BY J. M. DA COSTA, M. D.

*Professor of the Theory and Practice of Medicine in the Jefferson Medical College, Philadelphia.*¹

GENTLEMEN, I will to-day group together for you a series of cases of typhoid fever, which show a few rare complications and sequelæ. Perhaps some of the peculiarities of this affection may be best illustrated by the following specimens taken from a case that perished during the height of the disease:—

CLINICAL HISTORY AND MORBID ANATOMY OF TYPHOID; EXAMINATION OF THE HEART.

These specimens were taken from the body of a man who died in the wards a few days since of typhoid fever. His case was looked upon as hopeless from the beginning, for reasons which the autopsy has fully demonstrated to have been correct. His name was James Y., born in England, thirty-nine years of age; he was admitted into the hospital on the fourth of this month with diarrhœa. The record states that he had then been ill for nearly a month. He was a machinist, and had only been in this country a few months. At the beginning of his illness, it is said, that there had been no chill, the onset of the fever was gradual, but diarrhœa was a prominent symptom; he also had bilious vomiting, frequent epistaxis, and severe headache. Upon admission he had a dry cough, fever, and diarrhœa, his stools were thin, yellow, and frequent, so frequent that he had ten during the first day. From the first he had been troubled with a symptom which always makes one solicitous about a case,—he could not sleep; his temperature was 104.6° F.; the pulse was, however, only beating 80 in the minute; it was compressible and very weak. Upon examining his chest, we found slight dullness existing beneath the angle of each scapula. There was a good deal of hypostatic congestion in both lungs posteriorly, with coarse râles very generally distributed. But what struck us most forcibly, and what indeed made us think the case one of the greatest gravity, and most likely to prove fatal, was the state of the heart, the sounds were muffled, the first was only with difficulty detected; every now and then, about every second or third beat, there was a most marked intermission.

In consequence of his general condition and weak heart he was at once placed upon stimulants, at first wine, subsequently whiskey, gradually increased to twelve ounces in twenty-four hours, with four ounces of sherry wine. He was also steadily given strychnia, one sixtieth of a grain three times a day, in view of the fact that the great danger was going to be a failure in the action of the heart. This proved to be true; for while he remained weak, and was suffering with restlessness, delirium and tremor, the gravity of the symptoms was not so much due to the effect upon the nervous system of the typhoid fever poison, nor to the state of the bowels,—for the diarrhœa was readily kept in check with mineral acids and a little opium, in the form of suppositories,—as to the weak and irregular

action of the heart, which indicated grave disorder of the walls of the heart. Towards the end it became somewhat more regular, but it remained weak. I ought to state, also, that about five days before death there was a slight but not excessive epistaxis. The temperature all the time remained high, and on the day before death was 105° F. I will now invite your attention to the specimens.

Let us first confirm the diagnosis of typhoid fever by examining the intestines. Here is the cæcum, here the ileo-cæcal valve. These large ulcers in the wall of the ileum are remarkably fine specimens of the lesions of typhoid fever. Besides the great ulceration of Peyer's patches, these solitary follicles are in the same condition. Passing up the bowel, we find patches infiltrated, and with only superficial erosion, a condition not incompatible with recovery; others more affected are ready to slough away. The kidneys are large, somewhat fatty. There had been no albumen in the urine during life, and this fatty condition must be looked upon as due to a cause antecedent to the occurrence of the fever; it is not the form of renal degeneration which is often found in typhoid. Look at the spleen. As the intestinal ulcers were characteristic, so this spleen is characteristic. It is very large and full of blood, weighing twenty-five ounces; it constitutes a lesion almost as essential as that we have just seen in the bowel. This is the large dark spleen of typhoid fever, the currant-jelly spleen. The lungs show very marked evidence of hypostatic congestion at the postero-inferior portions, but there is no true pneumonia; the tissue crepitates, it is not infiltrated to the extent of consolidation, but simply engorged with blood, the congestion we recognized during life. The liver, also very large, weighs sixty-four ounces, at least fourteen ounces more than normal, it is dark-colored and exudes dark blood on section. The heart is fatty, the walls distinctly so. The leaflets of the tricuspid valve are healthy; those of the mitral valve are slightly thickened, especially at their free border, but were not sufficiently affected to permit mitral regurgitation during life. Now why did this man die? I believe it was from the fatty heart. Of course it was a bad case in itself, the temperature indicated that; it was, you recall the record, 104° F. to 105° F. The marked nervous symptoms also, which he presented,—the tremors, depression, and sinking down in bed, always indicate gravity; but with the condition of the heart these made the prognosis especially bad. There can be no reasonable doubt about one feature in the history, although the man was unable to give a full account of himself, yet the fact I refer to is confirmed by these appearances, the man had been very intemperate. The liver and kidneys show the intemperate habits of the individual. The same cause may have had much to do with the weakness of the heart, and the degenerative condition of its walls.

REMARKS ON SLOW PULSE IN TYPHOID.

Before passing to the next case I will make some remarks upon one of the prominent clinical features of the disease, which the case will bring to your mind—the slow pulse. I have said that the pulse was only eighty when he was admitted, although the temperature was 104.6° F. I have also told you that it was intermittent. Now, gentlemen, look at this disproportion between the pulse and temperature, 80 and 104° F. Is this a good or bad sign? It is a bad sign. A slow pulse is not of itself of grave import in typhoid fever,

¹ Reported for the Boston Medical and Surgical Journal.

for the case may be a very light one; but when the thermometer indicates a high temperature, then a slow pulse indicates danger. This is so true that when I find this disproportion existing between the pulse and temperature I know that I have so grave a case that in the vast majority of instances the patient will die. You may ask again, What is this slow pulse owing to? and why the irregular pulse? I attribute them in part to a peculiar influence of the typhoid fever poison; but largely to this, — it was acting upon a weak and fatty heart. It is a curious fact in fatty heart that in acute diseases, instead of becoming more frequent in its action, it becomes often slower. This is not an isolated case in my experience. I have known it to occur in pericarditis and other acute maladies. Therefore, a slow pulse in this case had to do with a condition of the heart which in itself is a cause of great danger.

But I should be giving you a wrong impression, if you have been led to infer, that in every case of slow heart, in typhoid fever, be it regular or irregular, this is the effect of a degeneration of that organ. That would be incorrect. I recall a case which I saw a few weeks ago, in a young man, too young to have fatty heart, where there was no question of intemperance, for he was perfectly free from bad habits; his pulse was 80, his temperature from 104° F. to 105° F., but the heart was not irregular as it was here. The slow pulse in the case I refer to was, therefore, not due to a fatty heart nor to any fault of the ventricular walls or valves, but to some peculiarity in the poison which prevented the heart from rising coincidently with the temperature. The case, after a long and desperate illness, proved fatal. Whatever be the explanation, a slow pulse and a high temperature are among the most dangerous combinations of symptoms of typhoid fever.

You will also be interested to learn — and I will now only call your attention to the fact, intending to return to it — that this man had epistaxis again only a few days before his death. Another case will furnish me with a better illustration to speak of this symptom.

A CASE WITH RECURRING EPISTAXIS AND PAROTID SWELLING.

I shall now show you a case of typhoid fever with most unusual complications, and one in which I have instituted a treatment, which has been followed by considerable success. This man has been in the hospital for seventeen days. His name is Emil B., twenty-seven years of age, a cooper; he is a German. He came into the wards a very ill man, having been sick for four weeks before admission with diarrhoea and weakness. He had headache, with a furred tongue, and vomiting, and yellow conjunctiva; indeed, there had been what is roughly and loosely sometimes called "a bilious complication" in the case, but this was all over before we saw him. He also had epistaxis, which from his history had been very free and frequently repeated; in truth it was stated that he bled at the nose every morning for a while.

Upon admission the man was found to have typhoid fever, he was very pale, weak, and feverish, the thermometer indicating 101° F., his pulse was 120 in the minute. He had frequent but not exhausting diarrhoea. He was so weak that we placed him promptly upon stimulants and quinine; and for the restlessness which he exhibited, he was ordered an ice-cap, to be kept upon his head. The looseness of the bowels was quite marked, but what is of more importance, he lost control

of his sphincters, and the copious frequent discharges were passed involuntarily so that it was difficult to ascertain the number of passages. Not to detail all the features of this grave case besides the frequent pulse, high temperature, and diarrhoea, I will say, in brief, that the looseness of the bowels was kept in check with opium, the restlessness was also relieved by this agent aided by the ice; and with steady nourishment, and twelve ounces of whiskey daily, the man rallied, and what seemed a very bad case soon showed great improvement. How bad a case it was you may judge from the temperature chart. Here it is: 104° F. the first night, 105° F. the next, then 103° F., and after that gradually declining to 101.5° F.; then, suddenly, up shoots the temperature again and becomes 104° F., and this rise, of which I am speaking, is found to be coincident with just the complication for which I wish to show you the case this morning. Look at it, or at least look at what remains to-day, for enough remains to identify it. See this dense parotid gland forming a considerable tumor on the left side at the angle of the jaw. This is a parotid swelling or a parotitis occurring as a complication of typhoid fever, and limited to one, for on the right side there has never been any such affection.

TREATMENT OF SWOLLEN PAROTID IN TYPHOID FEVER.

Now, gentlemen, this man, who was doing very well, when this swelling appeared seemed very ill, and the whole aspect of the case became more threatening; for this occurrence is one of considerable gravity. I will not dwell upon its pathology at present, but at once call your attention to the treatment instituted, a treatment which I have, in at least one case in this hospital, previously known to produce a remarkable result. It is the steady application of ice to the swollen gland. Mark you, the usual termination of this glandular inflammation in low fevers is profuse suppuration, long continued discharge of unhealthy pus, and a pyæmic condition; the state of the patient becoming more and more grave until he perishes from blood-poisoning or exhaustion. I have tried before now all methods of treatment, painting with iodine, the application of blisters, hot poultices, only to give them up as valueless. It then occurred to me that the steady local application of ice at the beginning might prevent this suppuration and the consequent exhaustion. We resorted to it as in the previous case, and the result was admirable. The swelling became less within twenty-four hours; the tenderness also was not so marked, the general condition much better. This was continued for several days with steady improvement. Yesterday, the resident physician, perhaps too soon, believing that the swelling was reduced and the inflammation over, suspended the ice treatment. Moreover, you observe that the temperature had gone down before that time from the effect of the ice, which acted as a general sedative. There was good reason then for interrupting the treatment, but what was the result? He has more swelling this morning. But we have not lost the good accomplished by the ice, merely the benefit of its continued use. There is no suppuration, the gland is hard, and tender, the surface red. I will resume the treatment, and unless I am very much mistaken, I shall be able to show you the case at our next meeting entirely free from this complication.

His pulse is now good, not over 100; his general

condition decidedly improved; the bowels are under control, but still require looking after; he is having three or four stools a day, when too frequent he is given an opium suppository from time to time; he has more strength than before; his tongue is cleaner; the mental condition has been improving. Therefore the group of symptoms which were at first so marked are now in abeyance. Notwithstanding that this glandular swelling is looked upon as a bad complication, I am disposed to continue his treatment for a few days longer, then if the condition is favorable I will abandon it, and apply iodine. He now is taking tincture of iron, twenty drops four times daily, and eight grains of quinine, twelve ounces of whiskey (half ounce every two hours in milk) through the day, keeping the bowels in check with a little opium by the mouth or in a suppository, given as may be necessary. The man made an excellent recovery. Towards the end a slight amount of purulent discharge was evacuated from above the angle of the jaw, where the ice had not been well applied.

The complication I have shown you here is one of the very rare ones in typhoid fever. I have seen it very often in what is called typho-malarial fever,—that is to say for the most part typhoid fever with malarial complications.

PATHOLOGY OF TYPHOID PAROTITIS.

I am speaking from a large experience with the disease when I say that it is also not uncommon in typhus, but in typhoid it belongs to the rarest of its complications. I have told you already that its tendency is to suppuration, which makes the condition of the patient much graver. But, gentlemen, unless the size of the swollen gland is reduced by resolution, it is better for it to suppurate than to remain enormously enlarged. I remember a case of typhus fever where it was necessary to resort to tracheotomy to prevent suffocation from the mechanical pressure exerted by the mass upon the trachea. If it be found impossible to prevent suppuration with ice, then the next best thing would be, I say, to encourage free discharge to prevent burrowing and pressure upon the air-passages. I have spoken of its rarity, now what is the cause of this complication? It is an expression of blood-poisoning. It belongs to certain low forms of fever in which the blood becomes profoundly altered, and the wonder is that it is not more frequent in typhoid fever than it is. It results, moreover, not only from a septicæmic condition, but also in the pyæmic state, which is more often seen in surgical than medical cases. In the latter condition it always indicates great gravity. I have not conversed with surgeons upon this ice treatment of gland swellings in pyæmia to prevent suppuration, but will suggest it, as it may prevent an additional drain upon the system. I believe it deserving of further trial.

SOME UNUSUAL SEQUELE OF TYPHOID.

We are dealing this morning with bad cases and rare complications. I now show you another typhoid fever patient, who has been very ill, and could not be brought into your presence before; he is now improving so that I can show him without any risk to himself. I will, however, proceed at once to examine him so as not to detain him in the clinic-room; I will then make some remarks upon the case.

His name is Martin M., twenty-one years of age, of Irish extraction. You see he is very pale, frightfully

anaemic; his mind is now perfectly clear; he passes out his tongue when told; it is not very much coated, you are, perhaps, struck more with its pallor than with anything else; his pulse is feeble, and beats 110 in the minute, it has been always about 120; his bowels are now regularly moved once a day, or sometimes only every second day; he has no tenderness in the iliac fossa nor indeed anywhere in the abdomen.

MILK LEG IN TYPHOID.

But now comes one of the symptoms which made this so serious a case, and of which you will see sufficient evidence remaining to identify the clinical history. He has had milk leg of very bad character, a phlegmasia alba dolens. Look at it. Although the leg is markedly diminished from what it was, you will still see that the right leg is considerably more swollen than the left. It has been still more swollen and very tender on pressure; the pain on pressure now has also subsided, except immediately along the course of the saphena vein, which is large and of cord-like density.

PURPURA DURING TYPHOID.

This swollen leg has been one of the symptoms from which this poor man has been suffering, now happily declining; it was associated for a time with considerable pain in the thigh and in the calf of the leg, but he also has had something else. Look at this left leg. Just above the ankle and on the dorsum of the foot see the large petechial spots, dark blotches, now only seen in this situation, but about a week ago they were all over the body, large purple and black spots in the skin, which have now almost all disappeared.

There is another point to which I will call your attention, and then will let him go out. In addition this man's life was almost ebbing away by profuse and repeated bleedings from the nose, so much so that the only means we could employ to stop them was plugging the nose, which finally arrested the hæmorrhage, which not only gushed from his nose but passed into the pharynx, and was swallowed, and afterwards vomited. This is a case of recurring epistaxis late in the disease. It was subsequent to these attacks of bleeding that these spots appeared all over the body, although a few had been observed before.

These are the principal features of the case. I will now only make an examination of his heart. I tell you that there is no valvular disease; the first sound is still feeble and laboring, the second is clear; a systolic blood murmur is heard at the right base as well as at the left, but more at the right. There is also a certain amount of bronchitis, for a number of mucous râles are heard in the lungs. This completes our examination of this unpromising case, and he can be removed to the ward.

TEMPERATURE RECORD DURING OCCURRENCE OF SEQUELE.

Let us now study his temperature record. His temperature this morning is normal. I will now show you some of the most interesting temperature sheets [Each sheet contains the record for four weeks. *REK.*] it is possible to see. Look at this last one, see the enormous variations during the last two weeks, now down to 98° F. then shooting up to 105° F. This is not the course of typhoid fever temperature. Look at it; it begins at the end of the second temperature

sheet, and here it is at its maximum. Now, the interesting part to us is that these temperature variations were accompanied by chills which were not influenced by quinine, and these temperature rises corresponded with attacks of epistaxis; during the last two instances this was noticed certainly.

This is not the temperature record of typhoid fever, certainly not the typical record of a man ill with typhoid, who has been in the hospital for eight weeks, and who has been sick at least nine weeks. It is, therefore, the record of these strange complications from which this unfortunate has been suffering. Milk leg, epistaxis, profound alterations in the blood, petechiae, and chills, the latter uninfluenced by quinine. What does it mean? It means that this man has been pyæmic. There has been septicæmia, milk leg, finally a pyæmic condition of the blood induced by the phlebitis, as shown by these irregular chills.

REMARKS ON EPISTAXIS.

This altered condition of the blood, which gave rise to this marked anæmia, was also the cause of the recurring epistaxis. Now, late epistaxis in typhoid fever as compared with early epistaxis is relatively very rare; it almost never occurs, although you have seen in this clinic to-day two marked cases which apparently prove the contrary. In the other case the epistaxis occurred within two or three days before death, but in this man it came on in the seventh or eighth week, when his life was threatened by the petechiæ (purpura hæmorrhagica). Gentlemen, epistaxis, as the rule, is an early symptom of typhoid fever, occurring prior to the decided development of the fever, or in the first week. Here you have had an illustration of how it may happen as a late complication, but when late it is a most dangerous one.

The treatment for the epistaxis, ergot, iron, locally and internally, was unsuccessful, until we finally resorted to the plugging of the nostril.

BLOOD CHANGES IN LOW FEVERS.

Finally, before dismissing this much-complicated case, I must say a word about the petechiæ. Do petechiæ belong to the clinical history of typhoid fever? Gentlemen, you may pass through a lifetime without being able to duplicate this case. These extravasations you will see in typhus or in cerebro-spinal fever, but they are most rare in typhoid. They bespeak a condition of blood that is serious in its results, a state of dissolution to an extreme degree, occurring very late in the disease. I have seen this also in typho-malarial fever — which is still typhoid — as it occurred in the army in soldiers who had acquired the so-called Chickabominy fever; among those who were thus brought to Philadelphia I remember a number had petechiæ.

PROGNOSIS OF CASE.

These are some of the leading clinical features, complications, and sequelæ of typhoid fever under rare conditions. This man has passed through a severe ordeal, but I believe that he will rally, and if we can get his blood in better condition I think we may now look for recovery. His temperature is once more normal, the milk leg is passing away, the chills no longer occur, nor the attendant phenomena that bespeak a condition of pyæmia from which he was once laboring.

His treatment now is fifteen drops of the tincture of the chloride of iron, with five of muriatic acid, which,

formerly taken thrice daily, we will increase to four times a day. He also gets five grains of quinine each morning.

His chances are now fairly good; a week ago you would not have thought he had a chance. There were no difficulties of diagnosis here; the early symptoms of typhoid fever were marked, very marked; it was always a bad case. We found before the peculiar sequelæ appeared, that there had been also a strong history of syphilis, although there were not any strong syphilitic manifestations. I mention this because it belongs to the clinical history, not because it had any especial influence upon the course of the disease.

Original Articles.

MORAL INSANITY.¹

BY GEORGE F. JELLY, M. D.

MORAL insanity, that is, insanity in which the moral or affective qualities of the mind are chiefly involved, was first described by Dr. Prichard, but found its most earnest advocate in the late Dr. Ray, to whom, more than to any one else, is due its recognition at the present time by both the medical and the legal profession.

I think that every one has been tried and puzzled by patients afflicted with this form of mental disease, and has approached its study with many doubts; but by writers on insanity, with occasionally an exception, it is as fully recognized as is melancholia or general paralysis. Still, even now no medical man can feel free from anxiety when he endeavors to give a victim of moral insanity the benefit of his opinion in a criminal trial, or even to have such a person committed to an insane hospital, he or she often appearing so well and talking so plausibly that an ordinary examination may fail to convince either judge or jury, while at the same time to the family and intimate friends the patient may be a terror.

True moral insanity may be defined as a disorder of the moral or affective powers of the mind with little or no apparent intellectual disturbance.

I do not mean to deny that there often and perhaps always is some intellectual impairment in cases of this disease, but what I do mean is that in those which are typical it exists only to that extent that the patient would be practically sane if the moral faculties were not disordered, and did not overpower the intellectual. The control of the moral by the intellectual powers is one of relative, not absolute, power. While the moral faculties remain in their normal condition the power to control their manifestations by the intellect is clearly evident, but when they become diseased the latter is unable to perform its office. Its own power may not be diminished, but the power of the moral sentiments is unnaturally or immoderately increased by the influence or intrusion of the foreign element of disease. This relation between the intellectual and moral powers is such that to render an act insane it is not material whether the derangement is in one or the other. As in other forms of mental disease a derangement of the intellect may lead to outrageous and immoral acts, so in moral insanity the morbid moral influences may be so strong that the intellect cannot control or resist them, the individual at the same time fully understand-

¹ Read before the Boston Society for Medical Observation.

ing what he is doing. For instance, a man may be overcome by an impulse to homicide or to some other unnatural act, the nature of which he clearly knows, and which he has resisted with all his strength till he can resist no longer, and he makes the plunge which proves him insane and irresponsible. Kleptomania, suicidal mania, and dipsomania are often of this origin, and the results of such a struggle. Cases of dipsomania are almost exact types of this disease; the patients, in the intervals of what may be called the paroxysms of excitement, are clear, well behaved, attentive to business and the ordinary duties of life, but when the impulse to drink comes they find it irresistible, though they know fully what they are doing, and its consequences.

I have recently been consulted by a lady of intelligence and good position who is thus overcome at every menstrual period, though reliable and to be trusted at all other times.

In many instances a well-marked depression precedes these outbursts, and sometimes there is some excitement or decided exaltation, which comes to be recognized by the friends, and not infrequently by the patient, as the precursor of an attack.

It cannot be denied that there is and always will be some difficulty in distinguishing this form of disease from moral depravity, and certainly no cases require more careful and patient investigation, and many interviews may be necessary to settle the question, but a thorough study will always reveal the difference. Moral wickedness will be shown by its ordinary characteristics, but in moral insanity the elements of change, disorder, and derangement will be found as in other forms of insanity.

Within a few days a young man was committed to the Boston Lunatic Hospital whose case is a marked instance of the periodical uncontrollable desire for liquor so characteristic of dipsomania. He seems during a portion of the time fairly well, and has no desire for drink, but suffers at irregular intervals from well-marked depression and wretchedness, accompanying or following which he has a most intense desire for liquor, which he will obtain by stealing, pawning, or any possible means. In my certificate for commitment I felt justified in stating that in my opinion the excessive use of intoxicants was one of the symptoms and not the cause of the insanity.

Perhaps I cannot do better here than to quote a few paragraphs entire from Dr. Prichard and Dr. Ray, though they are very familiar to many:—

Dr. Prichard says: "There are many individuals living at large and not entirely separated from society who are affected to a certain degree with this modification of insanity. They are reputed persons of a singular, wayward, and eccentric character. An attentive observer will often recognize something remarkable in their manners and habits which may lead him to entertain doubts as to their entire sanity, and circumstances are sometimes discovered, on inquiry, which add strength to this suspicion. In many instances it has been found that a hereditary tendency to madness has existed in the family, or that several relatives of the person affected have labored under other diseases of the brain. The individual himself has been discovered to have suffered in a former period of life an attack of madness of a decided character. His temper and disposition are found to have undergone a change, to be not what they were previously to a certain time;

he has become an altered man, and the difference has perhaps been noted from the period when he sustained some reverse of fortune which deeply affected him or the loss of some beloved relative. In other instances an alteration in the character of the individual has ensued immediately on some severe shock which his bodily constitution has undergone. This has been either a disorder affecting the head, a slight attack of paralysis, or some febrile or inflammatory complaint which has produced a perceptible change in the habitual state of his constitution. In some cases the alteration in temper and habits has been gradual and imperceptible, and it seems only to have consisted in an exaltation and increase of peculiarities which were all more or less natural and habitual."

Dr. Ray, in his Medical Jurisprudence, says: "A more serious error than that of limiting the influence of mania to them [the intellectual faculties] can scarcely be committed. It will not be denied that the propensities and sentiments are also integral portions of our mental constitution, and no enlightened physiologist can doubt that their manifestations are dependent on the cerebral organisms. Here, then, we have the only essential conditions of insanity, a material structure connected with mental manifestations, and until it is satisfactorily proved that this structure enjoys a perfect immunity from morbid action, we are bound to believe that it is liable to disease, and, consequently, that the affective as well as intellectual faculties are subject to derangement. In fact, it has always been observed that insanity as often affects the moral as it does the intellectual perceptions. In many cases there is evinced some moral obliquity quite unnatural to the individual—a loss of his ordinary interests in the relations of father, son, husband, or brother—long before a single word escapes from his lips 'sounding to folly.' Through the course of the disease the moral and intellectual impairment proceed *pari passu*, while the return of the affections to their natural channels is one of the strongest indications of approaching recovery. Such being the fact, it ought not to be a matter of surprise that in some cases the aberration should be confined to the moral impairment, the intellectual, if there be any, being too slight to be easily discerned. The doctrine that insanity may be confined apparently to the affective powers has been stoutly resisted by lawyers, by whom, during the last twenty-five years, it has been often pronounced to be without any foundation in true metaphysics, and dangerous in its consequences. They contend that insanity, such at any rate as annuls criminal responsibility, necessarily implies intellectual disturbance, and that unless this be established a person can claim no exemption from the ordinary consequences of crime. If the intellect be sound, they say, it perceives all the relations of the criminal act; there is no reasoning right from wrong premises, or wrong from right premises, and thus the individual acts solely in accordance with his own good will and pleasure. If he blindly follow the guidance of his passions, unheeding the voice of conscience or common sense, we are not warranted in taking his case out of the category of ordinary crime. In fact, every alleged case of moral insanity may be paralleled by one of proper moral depravity universally recognized and admitted as such. By those who reason thus, the admission that the intellect may possibly be disturbed though the fact cannot be demonstrated, is deemed to be insufficient, because the intellectual disturbance (in their

view) must be manifested in an inability to recognize some of the qualities of crime, and, therefore, so long as these are correctly discerned there can be no intellectual disturbance, none certainly which a court of law need take into account.

"If we choose to indulge in metaphysical subtleties we may, no doubt, arrive at one of two conclusions equally false: either that all criminals are insane, or that every insane person, unless actually raving, is responsible for any criminal act which he may commit.

"But common sense and professional experience teach us that there is a distinction, obvious enough for all practical purposes, between the depravity which belongs to the character of the man and that which is the result of disease or congenital deficiency.

"Here it is enough to say that the former is marked by method, object, motive, deliberation, coolness, and consistency; the latter by impulse, agitation, nervous excitement, and unnatural conduct. It is not generally understood that in a large proportion of the insane, leaving out of view the imbecile and demented, we observe no delusion or hallucination, nor, it may be, any other derangement of the intellectual faculties. Some of them may not evince all their natural strength and sagacity of mind, but their discourse is always coherent, correct, and pertinent, exhibiting nothing that in itself can be regarded as indicative of disease. Others may show a degree of shrewdness, promptitude, and vigor scarcely manifested in their best estate. Now the insanity of these people is not questioned. They are regarded as unfit to be at large, and by universal consent are confined in establishments for the insane. Their disorder is exhibited not in intellectual aberration, but in morbid exaltation and depression, so that they are ardent, sanguine, and full of schemes of advancement, or sunk in the lowest depths of despondency, and revolving thoughts of self-destruction, in unnatural indulgence of appetite, in moral perversions which render them quarrelsome, vindictive, savage, impatient of contradiction, careless of appearance, regardless of domestic proprieties, and indifferent to the feelings of others. For a different purpose it has been said that the very fact of a person's being under the undivided dominion of the affective powers and yielding to their paramount influence is of itself sufficient proof of intellectual impairment. This position can hardly be maintained without ignoring a matter of common observation, that within certain limits the moral and intellectual faculties act independently of each other. Intellectual power and the perception of moral truth frequently do not exist in the same degree in the same person, and they do not develop equally. Moral insanity often precedes and passes into outbursts of general mental disease, and sometimes the moral disturbance persists when all other derangement has disappeared; and a person can only be well when not only are hallucination and intellectual disturbances of all kinds gone, but when, also, he has at the same time returned to his natural feelings."

Dr. George H. Savage, superintendent of the Bethlehem Hospital, in an article in the *English Journal of Mental Science* for July, says:—

"It may seem to the philosopher rather a mistaken way of considering the mind to divide it into intellectual and moral components, but we in asylums have constantly to take notice of cases in which the moral side of the patient suffers very much more than the intellectual; and though I should not deem any per-

son capable of being intellectually complete and yet morally defective, I would maintain that the defect on the intellectual side may be so little appreciated, or of so little importance in reference to the individual's relationships with the outer world, that it may be disregarded.

"I would say that I look upon the moral relationships, so called, of the individual as among the highest of his mental possessions, that long after the evolution of the mere organic lower parts, the moral side of man developed; that the recognition of property and of right in property developed with the appreciation of the value of human life; so that the control of one's passions and of one's desires for possession and of one's passion for power developed quite late in man, and, as might be expected, the last and highest acquisitions are those which are lost most readily. It is often noticed that in cases in which slow progressive nervous change takes place, the moral relationships are the first, or among the first, to be affected; and in the same way after an intellectual storm it is no uncommon thing to see the intellect partly restored to its normal equilibrium, but still wanting the highest and most humane of its attributes, high moral control; so in the emotional states of acute mania, of general paralysis, or of chronic insanity, we have corresponding defects in this highest intellectual control."

DIAGNOSIS.

The diagnosis of moral insanity is not always readily or rapidly made, but here, as in all forms of disease, patient investigation will generally reveal a cause. The patient should be compared not so much with others as with himself; in this sense a man is properly a "guide unto himself." We must convince ourselves in all cases whether in the particular individual under consideration "there is, according to the old definition, the prolonged departure without adequate external cause from the states of feeling or modes of thinking usual to the individual when in health." In mere vicious impairment of the moral powers there has been no change of character dependent upon fever, apoplexy, injury to the head, or other notable disease or shock, but the power of desire and of unbridled propensities has been of slow growth, arising from frequent indulgence. The law has always recognized a difference between passion as the result of disease and passion which is the result of indulgence, correcting the latter by punishment but giving the former medical treatment. It is necessary to go carefully back and learn the entire history of the person we are examining. For instance, when a man of character and good standing is arrested for stealing some article of little value (and of no value to himself) suspicion of insanity would at once be aroused, and it may be found to be one of the earlier manifestations of general paralysis. In another case an unaccountable perversion of feeling and conduct may be finally explained by the occurrence of epilepsy. This test can, however, be applied only where the mental disease is acquired. To those congenitally deficient in intellect it will not apply; the natural character, being abnormal, cannot be used as a normal standard. In these patients the natural deficiency can be traced to the earliest childhood, the patient having been perverse, wrong-headed, and capricious from birth. Dr. Woodward believed that besides a disease of the moral powers there is in some cases a condition like moral idiocy, which renders the

individual morally irresponsible from birth. There certainly can be fair intellectual ability with congenitally feeble moral powers. Such a person should not be held responsible for any criminal act which he might commit.

CAUSE.

Of all causes of moral insanity heredity is the chief, a patient's parents or near relatives having been insane, or drunkards, or eccentric, or having been instances of the insane temperament. The change in the system at time of puberty is a frequent cause, both in young men and young women, and the disease often originates in epilepsy (which has not produced apparent organic change in the brain), in injuries to the head, in debilitating sickness of any kind, in shocks or severe mental strain, and in previous attacks of mental disease.

PROGNOSIS.

The prognosis is always doubtful and generally unfavorable, the strong heredity and the manner of development in so many cases indicating an impaired or weak organization.

In some instances recoveries take place, but the tendency is to a weakening of the intellectual power, ending in dementia, if the patient live long enough, often by the development of other more severe forms of mental disease.

Very little can be said in the way of treatment. A patient should be put under the conditions most suitable to encourage moral control. He should be removed from temptation as much as possible, and any physical disease should receive appropriate treatment. Undoubtedly the *régime* and restraint of a well-organized and well-regulated hospital for the insane afford the patient the best chance, though no class of patients is more to be dreaded in such an institution, on account of the demoralizing influence which they exert upon their fellow-patients and the anxiety and annoyance which they cause the officers in charge. Such cases should, however, always be sent to a hospital where the patients have regular employment, and should be obliged to work as a means of cure.

One of the patients whose history I shall give seemed to derive benefit from the rigid discipline of the House of Correction at South Boston, but I think that we would hardly be justified, as physicians, in advising such a course of treatment.

I have selected for purposes of illustration some cases which were under my observation at the McLean Asylum, and concerning whose history I have refreshed my memory from the records through the courtesy of Dr. Cowles.

I have taken these from many others because I have been able to follow the patients for several years, both while they were at the asylum and subsequently, and also because they have been known to several other members of this Society.

CASE I. A. B., aged twenty, single, admitted to the asylum March 28, 1876. An aunt died at the Boston Lunatic Hospital. Was, as a young boy, remarkably conscientious and truthful, a fine scholar, and in every way promising. Four years previous to coming to the asylum was injured at school about the head, though the cause of the injury is unknown. Was unconscious several days. Soon after his recovery from this accident his family first noticed peculiarities: he would borrow money without any apparent reason,

and gave the impression that he was wealthy. Developed a great fondness for horses; would hire one for half an hour, then another one, till he had tried several. He was excited easily when opposed, became utterly unreliable in word, telling the most outrageous lies unblushingly, gambled and drank, manifested slight alternations of mild depression and exaltation, borrowed money of every one. General health has failed. A month previous to coming to the asylum went to Maine. Left there without knowledge of friends and went to New York. Soon after was heard of in Boston, frequenting the lowest resorts. No shame. Very plausible. Came to asylum willingly to please his mother, the only person for whom he has any regard. When admitted he was suffering from gonorrhoea, which was followed by orchitis which was extremely painful. He was easily excited, but never manifested any delusions, though there were slight periods of depression and exaltation. At first he was quite indifferent, but as he gained in strength he became more natural, and seemed to try earnestly to gain self-control. The irresponsible element in his case was very apparent, he often saying, and I think with honesty, that there were times when he could not control himself.

His moral sensibilities were very much blunted, though he never lost the knowledge of right and wrong, and was rather above the average in intellectual ability. Two months after admission he escaped over the fence, breaking his word to do so, and went directly home. His mother persuaded him to return, which he did in a day or two, upon her promise that he should leave in three months from his admission. He remained till the end of that period, when he was discharged in good health, and having full faith in his ability to do well, a faith not shared in by any one who had known him at the asylum.

In a month he was returned to the asylum with a history of lack of self-control, drinking, carousing, and spending money which he had obtained by forging checks on his father, etc. He would make these checks payable to his own order, sign his father's name, indorse them with his own name, all in one handwriting, and then present them to the bank, manifesting no fear of detection, either then or afterwards, and never hiding from pursuit. When brought to the asylum this time he had been drinking. As there was some informality in the certificates he was discharged the next day, but was arrested the same evening, and was committed to Taunton Hospital the day following on the certificates of Dr. Fisher and myself. From Dr. Gidding I learned that he exhibited the same characteristics as when at the McLean Asylum, and that all who saw him were convinced of his irresponsibility. After many months' residence there he was discharged, and sent by his friends into the country. He did well for a time, but again forged, and was arrested and lodged in jail at East Cambridge. There I examined him with Dr. Taylor, the physician of the jail. His case presented the same peculiarities as before. A period of good behavior had been followed by a period of slight depression, an uncontrollable impulse to drink, then by forgery, conducted without any discretion and in the same way as before, resulting in sure detection (which he did not avoid) and in his arrest. Both Dr. Taylor and I were again convinced of his irresponsibility. We so certified to the judge of the Superior Court, the indictment was quashed, and he was sent to Taunton Hospital by order of court. He remained

there again about a year, I think, eloped, and went to sea. He went to the West Indies, was very ill, returned to Boston, commenced his old course, committed his forgeries exactly in the same way, was again arrested, and lodged in Suffolk County jail. There Dr. Fisher and I again examined him, and found the same elements of weakness and irresponsibility. We endeavored to give him the benefit of our opinion in court, but the jury did not agree with us, and he was sent to the House of Correction for eighteen months. There he conducted himself with propriety, was given charge of the library, and many privileges, none of which he ever abused. He served his sentence, and was discharged last autumn. He called on me several times in the weeks following, seeming in good health and to have perfect control of himself. He believed that the rigid discipline of the prison had been an excellent thing for him. He subsequently went to the western part of the country, and so far as I have learned is doing well and is at work.¹ Should he now prove that he has recovered, his case would, I think, be a remarkable one. No one who should see him now could doubt his honesty of purpose. During all his attacks, and at the present time, there has been and is no diminution of intellectual power, and there have never been delusions, so far as could be ascertained.

CASE II. J. L. J., aged twenty-two, single, native, and resident of Boston. Admitted to the asylum May 30, 1873. My first knowledge of him was derived from the following letter written by his family physician (Dr. F. G. Morrill):—

"A friend and patient of mine has a son who steals everything which he can lay hands on. He has everything that is necessary for his comfort, a good home, good clothing, and an ample allowance of spending money; is treated kindly, and has every possible encouragement to do well. But notwithstanding all this he will steal the jewelry and wearing apparel of members of his own family and their friends, and pawn them for a mere song. What he can do with the money no one can find out. He does not drink, and is not known to frequent bad women. [In both these particulars his history, learned afterwards, proved the doctor mistaken.] He is an organist and has been one for a year or more certainly. I have no doubt whatever that he is insane.

"I cannot tell you the care and anxiety he causes his parents, who are most worthy people, and have tried every means in their power to reform him. They are willing and able to pay for treatment, but are afraid that you would not be willing to retain him long enough at the asylum to work any permanent good. His family are in the highest degree respectable."

I replied that he could be received, and he came to the asylum on the certificates of the gentleman who had written me, and, I think, Dr. Fisher.

He came quietly and without opposition. No hereditary disposition could be learned, but on acquaintance I found his mother an eccentric woman. On admission he seemed indifferent and careless, but presented no marks of delusion, and conversed clearly and intelligently. His friends represent that he was reliable and conscientious till within a year or two previous to coming to the asylum, and that then, without known cause, he changed and began to present the characteristics described in the letter previously quoted from.

¹ He is employed on a good salary in a large mercantile house.

For some time he remained quiet and indifferent, complaining occasionally of headache and dizziness, and was soon found utterly unreliable. He was inclined to be mischievous and to tease other patients, was restless and threatened to run away. After two months he climbed a fence from an inner to an outer yard, to see, as he said, "what there was there," but was brought back.

Four months after admission the record reads: "Little change, still mischievous, and fond of playing tricks upon other patients. Sometimes very irritable, profane, and fault-finding. Obscene, and fond of talking of his exploits with women. He was found to have a gleet, about which he manifested no shame, and of which he often talked to others with some apparent pride. Totally indifferent to family and friends. Threatens to elope but says that he can stand it as long as they (his friends) can. Is anxious to procure liquor or stimulating medicines, and sometimes feigns sickness in the hope of obtaining one or the other. When reproved manifests some penitence and promises to do better. At these times seems honest but lacks the ability to carry out his purpose. Manifests decided, though slight, alternations of depression and excitement. Childish at times, and, like a child, asks for childish favors. Sometimes requires to be denied privileges to induce him to exercise more self-control." This was a fair account of his condition for the first four or five months of his stay at the asylum. After that he manifested some improvement. Was more gentlemanly, manifested less petulance and more strength of mind, was more uniform and rather more reliable, and his regard for his friends returned. Still he seemed weak and no great amount of dependence could be placed upon him. About fourteen months after his admission to the asylum he was anxious to leave, and he was discharged at the request of his friends, they having become wearied, apparently, with his importunities. They adopted, upon their own responsibility, the somewhat novel expedient of sending him to Kentucky with only money enough to pay his fare and his board for a few days, and then letting him shift for himself. He went to Kentucky, soon became destitute and fell into his old ways; his father sent money for him to return. He manifested the same unreliability and was soon after sent to the Taunton Hospital. There he remained a year or two, and was finally discharged *improved*. He came home, and now for more than a year has been a bookkeeper in this city. Has controlled himself, has given his employer satisfaction, and seems well. Should he continue as now, we may, I think, properly regard him as recovered. No one could doubt his unreliability and irresponsibility, and when he left the McLean Asylum I had no faith in his power to control himself for any length of time. He is kind and attentive to his friends, and especially solicitous for his father, who is feeble from paralysis. It is seven years since he first came under observation.

CASE III. The third case which I shall describe is, to my mind, one of the most typical instances of the form of disease which we are considering. H. T. First admitted to the asylum December 18, 1874. Single, aged nineteen, grandmother insane, mother flighty and unsettled during every pregnancy, and always a weak, nervous woman. Has never been a remarkably strong-minded boy, but is of average intelligence. Two years before coming to the asylum his friends first noticed peculiarities. He would take articles from his father's

store, pawn them, and gamble with the proceeds, manifested no shame afterwards for a long time. He seemed for a time to be utterly controlled by this passion for gambling, and to have no moral power of resistance.

These exhibitions, the records say, seem to come on in paroxysms, and after a few weeks he seems more reasonable, is sorry, for a while, does fairly well, till another paroxysm comes on, and the same things are enacted again. He drinks, goes with women, and undoubtedly masturbates. He has gradually grown worse. Threatened to shoot his father because he prevented him from marrying a young girl (whom he some months afterwards seduced), and also threatened suicide. After a course of drinking and gambling he once manifested some intellectual aberration. At one time thought that he fell from the dome of the State House. Memory somewhat defective. These attacks come on with constipation, followed by voracious appetite and severe pain in head.

On admission, sullen, weak, but quiet. Slept well the first night. The next day, moody, irritable, and fault-finding. Has a very voracious appetite. After a few days became more pleasant, and continued so for some time. Said he had tried in every way to make us believe that he was well, but might as well give up as he could deceive no one. Some alternations of depression and exhilaration not very marked. Gained for the first four months physically but not mentally. Manifests some periodicity in his disturbances. When they come on he is very morose and loses his self-control. Annoys every one around him. Sometimes, when opposed, throwing articles about his room. When comfortable he is very plausible, quite gentlemanly, but very unreliable.

After about five months there was some improvement, but not much. Sometimes angry and threatening. Very plausible to his friends, whom he persuaded to remove him without special mental change.

He conducted himself pretty well for a time after his discharge, and returned to his father's store. He was free from special manifestations of the disease for some weeks, then began to pawn, gamble, drink, frequent bad houses, and to manifest sullenness, anger, and suspicious. He would pawn all his clothing except just enough to cover him, although his father gave him a liberal allowance. He struck his brother when he interfered: was arrested and put in a police station for the night. Returned to the asylum next day, eight months after his discharge. During this residence of eleven months he manifested the same symptoms, in an aggravated form, as during the previous residence. At first there was evidently a good deal of suppressed excitement. Sometimes sullen, and depressed, sometimes jovial, and sometimes restless like a caged bird. Always tricky, unreliable, and lacking in self-control, and a very unsatisfactory, annoying patient both to his companions and the officers of the institution. Threatened suicide to his father at one time when visiting him. When asked about it laughed and said he wanted to scare him. After several months' residence he grew calmer and more self-controlled. Then admitted his former lack of control and seemed to make some effort to do better. Discharged after eleven months, at the request of friends.

Remained away from the asylum fourteen months, when he was returned with the same history and the same symptoms, but conducted himself pretty well for

a longer time after his last discharge. Then the seemingly irresistible impulse came on and there were the same stealing, pawning, gambling, drinking, and threatening, with alternations of sullenness and irritability. When he returned to the asylum, February 10, 1878, he had gonorrhoea, which was accompanied by orchitis of both testicles. The extreme pain of his testicles seemed to have a good moral effect upon him, and he did well for a time, but afterwards manifested the same utter unreliability. He gradually gained more self-control, but was restless, unsettled, taking every mean advantage possible, and was one of the most troublesome patients. He was discharged after seven months more comfortable in some ways but essentially the same. His former history was again repeated. He did well for a time, the irresistible impulse came, and he pursued the same course; threatened his mother, pawned everything he could find, was arrested, and I was asked to see him in the station house. I found that he had deteriorated mentally, manifested the same irresponsibility, and with another physician took him to the probate judge for commitment to the McLean Asylum. After five minutes' examination the judge declined to commit him, as he talked very clearly and plausibly, and said that he would put him "on probation." After six weeks more, he in the meantime keeping his mother in constant terror, he was again arrested. I again examined him and he was then committed for the fourth time to the McLean Asylum, in January, 1880.

I have made a longer history of this case than I could have wished, but perhaps not long enough to convey the impression which even a short personal acquaintance could not have failed to give. He inherited insanity, congenitally was not well balanced, and he has steadily gone on from bad to worse, losing in self-control and moral power but never manifesting any marked intellectual aberration, or anything which had any resemblance to a delusion, except once, for a short time, after a course of drinking and gambling. I can see nothing in store for him but a constant repetition of these attacks and eventual dementia, if he live long enough. In his early attacks I think that he sometimes honestly tried to do well, but I now doubt his intentions as much as I believe in his inability to control himself.

A GRAVE DEFECT IN OUR MEDICAL EDUCATION.

BY CHARLES SEDGWICK MINOT, S. B., S. D.,

Lecturer on Embryology at the Harvard Medical School, and Instructor in Oral Pathology and Anatomy at the Harvard Dental School.

For some time past I have been interested in certain questions of medical education. Various circumstances have conduced to bring me to the conclusion that several important, I might almost say fundamental, changes should be made in the arrangement of the earlier and strictly scientific branches of medical instruction. It also appears to me desirable to alter to some extent the subjects themselves. As the notions to be advocated are partly novel, and perhaps peculiar, it seems to me desirable to preface what I have to say with a brief explanation of a personal nature.

I am not a physician, and have never had any intention of becoming one. For many years I have

been aiming to fit myself to become a professional zoölogist. At the time when I began my studies the conception of biology as a distinct science did not exist in this country, and our naturalists were, with a few brilliant exceptions, apt to be either narrow specialists or else superficial. In striving after a more general training, the importance of which was then just beginning to receive recognition and commendation, I soon found that there were many things that I ought to know, which I could not hope to secure from any of the current zoölogical instruction, but which I might secure from the medical schools. I therefore pursued for several years those medical studies which are commonly designated as scientific, and which may be of immediate utility to a zoölogist. It thus happens that I have had opportunities for becoming familiar with the methods and needs of an important part of medical instruction. I hope that this much of personal digression will be deemed pardonable, since it explains how I was brought to hold the following views.

Physicians are often struck by the extent and variety of ground over which their training carries them, and they are certainly justified in regarding medical education as liberal. Yet their mental attitude is often illiberal in one important respect. They measure the value of everything by its immediate relation to man, and consequently they lack, as a class, appreciation for the broader aspects of biological science, and really rarely understand that the whole of medical science and art together make but a small part of zoölogy. Indeed, the physician occupies the same relation to the investigating biologist that the technologist holds towards the chemist. In a philosophical view of these connections practical medicine is upon a par with, for example, economic entomology, as regards its relation to the science of life. This is, I think, seldom clearly understood by medical graduates.

Now this might, perhaps, not be of great consequence were it not that a considerable portion of the ablest physicians carry out original investigations, partly purely scientific, partly, of course, with a view to applications in medical practice. Now, these researches are often of very great value, but they lose an immense proportion of the worth they might have because the physician has never learnt to understand, even imperfectly, the problems of comparative morphology, physiology, or pathology. This assertion is made advisedly, and if it had been made much more forcible it would have still been true.

The question therefore arises whether it is advisable to attempt to remedy the matter, by so far changing our usual medical instruction as to impart to our students a correct appreciation of the true standing of medicine and of the lesser intellectual importance of medical problems as compared with the greater importance and wider bearing of biological problems. It seems to me that it is, since some of the best students are to become investigators.

For this reason a special course on biology might be added to the curriculum. This appears eminently desirable when we consider that biology has a very great number of immediate and practical applications to medicine. There are the great fields of medical botany, vegetable and animal parasites, the animals useful to man, the theory of inheritance and reproduction, the laws of embryology, the anatomy of the domestic animals, and the comparative anatomy of the animals used for physiological experiment, and so on.

By a judicious and painstaking selection a general course might be arranged in which the leading laws of life and the general principles of botany and zoölogy should be succinctly expounded, while likewise including a fuller treatment of comparative anatomy and physiology, devoting most attention to whatever is of interest and value to the student of medicine. It would require a courageous and enthusiastic person to carry out this plan successfully. Probably the subject of embryology might be best given in connection with the course suggested, because our knowledge of embryology is derived mainly from animals.

The advantages to be reaped from this change being admitted, the objection will probably be made that our students are already so overcrowded with work that neither their time nor their strength will permit any such additions as proposed to the requirements already made of them. But I believe, on the contrary, that in the end the student would find all his studies lightened very essentially. There are many things which he has now to learn empirically, and which he would then be enabled to arrange in a clear and reasonable intellectual order. Moreover, many of his notions would be rectified. How many students acquire just ideas concerning bacteria, poisonous animals, the way in which protophytes multiply and pollute fresh water, the metamorphoses of parasites, or of how to translate into terms of human physiology the results gained by experiments upon animals? Yet all these matters, and many others like them, would belong in a course on medical biology.

Assuming, now, that the course we have recommended is admitted to be both desirable and practicable, it still remains to inquire at what period of the student's career it should be introduced. I think at the very beginning, for the following reasons:—

(1.) It forms the most appropriate introduction to the whole course of medical instruction. Is not this a necessary consequence of the subordination of medicine to the general science of life? Of the fact that medicine is only a branch, and by no means nor in any sense even the chief branch, of biology? Supposing that a polytechnic school should attempt to train a chemist for dyeing and printing mills, and should give him no systematic instruction in the principles of chemistry, but only so much as happened to turn up in connection with the special instruction about dyes, and so forth, would not all agree in condemning the method? Yet this is precisely what all our medical schools are doing without a word of condemnation ever being said against them. Undoubtedly medical training warps the mind, yet surely every intelligent physician must recognize that his art is merely the practical application of the laws of biology to special and restricted uses,¹ so that it would be really an economy to teach the student of medicine those laws of life which especially concern him, rather than to leave him to pick them up at hazard incidentally in the course of his special studies.

¹ I am afraid that my position here may be misconceived in view of the fact that the greater and most important part of the history of medicine, of its development, has been quite independent of biology, that is, biology in the restricted sense. It seems to me that we cannot justify continuing a separation which prevailed in the past when knowledge was fragmentary. We might with equal propriety maintain that dyeing was not applied chemistry because the art of dyeing arose from empirical knowledge, which was only later verified, extended, and improved by scientific chemistry. I should regret very much to have the reader think that I overlooked the fact that the best part of practical medicine rests on an empirical basis, while comparatively little has as yet been contributed by pure science.

(2.) It would essentially lighten his pursuit of anatomy and physiology, which, under the present prevailing arrangement, he enters upon at an extreme disadvantage. Leaving out of consideration those wretched schools which have no distinct course of physiology, not having yet attained a comprehension of its indispensability, we find that it is usual to begin both anatomy and physiology at the opening of the first term. In the anatomical lectures the bones are taken up first, and occupy many weeks, during which the unlucky students are expected to listen with profit to elaborate explanations concerning the functions of organs of which they very probably have never heard even the name before. One is never quite able to comprehend how an intelligent set of men can go on year after year in apparent unconsciousness, continuing so obvious a blunder. It may, perhaps, be said by some one that this criticism is unjust, since there are too often practical difficulties which interfere. To this comment the response is that the evil is so serious an impairment of the value of the studies, that hardly anything short of sheer impossibility of change can excuse the continuance of the present disordered methods. Certainly no school which permits so bad an arrangement to be kept up can justly be said to be managed with thorough efficiency. The difficulty might be obviated by commencing the anatomy with the treatment of the viscera, so that the physiologist could turn immediately to the discussion of digestion, respiration, and excretion, and find his audience prepared to comprehend him. There are, indeed, practical reasons for dealing with the bones first, namely, the ease with which they may be preserved and always supplied in sufficient abundance to every student, and, on the other hand, the difficulty of procuring and keeping subjects for the demonstration of the soft parts in the autumn before the season of cold weather. In spite of these reasons it still, I think, remains advisable to change the order, because it is all important to enable the student to begin his dissections with a preliminary knowledge of what he is to learn from his work in the dissecting-room. In any case this clashing of advisability and convenience would cease if the student were instructed in the general principles of anatomy and histology as recommended.

(3.) It would more accurately impart the principles that govern the organization and functions of the body. Anatomy, for example, necessarily enters on so many descriptive and topographical details that the laws of morphology are easily lost sight of. How many of the graduates of our medical schools appreciate the fact that the structure of man is entirely subordinate to the division into three germ-layers, the separation of the body into two systems, the neural union and the independent cells, or are aware that the vertebrae do not correspond to the segments of the body, but to the divisions between the segments? Or, if we turn to physiology, how many students become familiar with the effects of ether and other substances on the individual cells, or comprehend the importance of the pseudopodia in the ingestion of food by epithelial cells? Such questions might be multiplied almost indefinitely, but surely the position taken does not need ampler justification.

Generally speaking, the chief defect of medical education at present, I think, is that the student is thrust forward into new subjects before he is prepared to reap the full benefit of them. He goes to dissect the soft parts when all his anatomical knowledge is about

bones; he listens to lectures on the process of digestion before he has heard of an epithelium, a peptic gland, or the duodenum; he makes analyses of urine, normal and pathological, before he has seen renal tubules or learned the nature of the diseases whose abnormal products he laboriously examines. All this involves a frightful waste of labor and time, and constitutes an imposition upon the student, and, one is tempted to add, a fraud upon the community. This is strong language, but I think the case calls for it, because the evil is patent and great, and the remedy entirely feasible.

Time should be allowed the student to acquire a general knowledge of anatomy, especially of histology and the structure and relations of the soft parts, before entering upon the study of physiology. He ought also to have a little knowledge of pathology before beginning with pathological chemistry. Now, I believe that all these general and introductory matters might be most successfully treated by beginning with a succinct course of medical biology, which would naturally, I might say necessarily, precede the others.

To conclude, the arrangement which I at present consider the best would be, for the studies of the first year (comprising two terms), as follows:—

First term: anatomy (beginning with the soft parts), histology, general chemistry, and biology.

Second term: anatomy of the bones and muscles completed, topographical anatomy, physiology, medical chemistry, and general pathology.

It is proper to add that the entirety of the views above advanced are merely personal opinions of the author, and could doubtless be improved and rectified by opportunities for discussion with a larger number of experienced medical instructors than the author has yet had the pleasure of conversing with upon these questions.

REPORT ON PROGRESS OF DENTISTRY.

BY T. H. CHANDLER, D. M. D.

DENTISTRY, in its progress, seems to have come to a pause in the direction in which for many years it has been so active, namely, in operations on the teeth and the manipulation of gold, and to have turned back to take up again the long neglected and despised mechanical methods and appliances. Some few are still at work on the minute microscopy of the tooth substance, and claim to have discovered, under the guidance of Heitzmann, a living network branching in every direction and penetrating the formed material, uniting the offshoots from the nerve substance or tooth pulps, the soft solids as they are often called, and explain in this way the mysterious sensitiveness of dentine, which has up to the present so puzzled all workers on the teeth, and claim to show how the tooth itself is built up and nourished.

Legros and Magitot in France have investigated the tooth follicle, and their original memoir has been done into English with additions, fitting it for an elementary text-book, by Dr. M. S. Dean of Chicago. Kingsley's Oral Deformities has been added to the literature on this side of the Atlantic, and on the other several books of less pretension, chiefly upon mechanical dentistry. Several new dental magazines have come into existence, without adding much to the quality, but a great deal to the bulk, of the read-

ing matter which every progressive man is expected to peruse. The *Dental Cosmos* still keeps the lead of the magazines, and within a short period has much improved in the quality of its articles.

The new English Registration Act has given a fresh impulse to dental education which the dental schools in this country are feeling. Out of the "bogus diploma" business has sprung a desire to investigate the character of those schools which issue *bonâ fide* degrees, which has been greatly strengthened by the vigorous measures taken by the German government to prosecute all whose diplomas cannot be shown to have been honestly obtained from an authorized source. Letters are coming from abroad inquiring into the standing of the various schools, and the worthy will in the near future reap the benefit. On the other hand some of our States have lately granted articles of incorporation to schools whose diplomas are or may be given *sine curriculo*, on examination merely, or even without examination, for a stipulated payment of cash in hand. Says one of the announcements, "Students receive diplomas, degree D. D. S., for what they know and can do, and not for the number of terms spent at the college." The clause allowing five years of practice to take the place of one term in the school still exists in some of the dental colleges, a certificate only being demanded from a known or unknown practitioner to permit the student to enter at once upon his second year, and be graduated with his parchment in due form in one short term of four or five months.

"Owing to the great advances made in the *methods of instruction*," the faculties of one medical college and of one university give "the two degrees, in dentistry and in medicine, in *three years*" of five months each. Two years are necessary, according to them, to obtain the dental and three years for the medical diploma, yet by some strange process of condensation both degrees may be had in three years. This record shows that there is still room for improvement in the matter of dental education, though why institutions of such standing as the Jefferson Medical College and the University of Pennsylvania should go so far out of their way to cheapen their degrees, passes ordinary comprehension. The Wisconsin School, regularly incorporated under the laws of that State, offers by circular to all comers its honorary degree for twelve dollars cash paid. The tendency to multiply schools of dentistry is to be deprecated, as it inevitably tends to cheapen the degree and to lower the standard. With too many the sole object of attending a school is to obtain its diploma for use as an advertising medium, and not for the education to be had, as is surely shown by the success of Buchanan and his imitators. With the demand comes the supply, and multitudes of dentists possess diplomas of slightly greater value than his, though regularly obtained from regularly organized and recognized schools. Yet, on the whole, the cause of dental education is advancing. A few of the best schools are honestly taking such measures as their circumstances permit to advance their standards, and graduate men whose student life will not end with the reception of their diplomas, whose promise is of honor to their training and their chosen calling.

As was said at the outset, operative dentistry has apparently come to a pause in its career, and the army of practitioners is dividing its forces: "Some for Paul and some for Apollon;" some are looking back to the old-fashioned soft foil, and the ancient methods, as

though all that is new is vanity, and "there is nothing new under the sun;" still others seem to think all that is old is worthless, and nothing of value that is not "brand new." Such adhere to the use of cohesive gold, or follow the leaders of the "new departure," whose gods are amalgam and other plastic materials; who declare that "in proportion as teeth need *saving*, gold is the *worst* material to use;" and that "a filling may be the *best* known for the tooth and yet *leak badly*." (Italics not mine.) As long as these varying methods are in the hands of thoughtful men, some good may come out of the evil, and the pause may be but the precursor of another era of progress. Skepticism leads to inquiry as well as the bold assertion of startling propositions. Men will at last be brought to examine and compare, and he that is honestly seeking the best way for himself and his patients, who is not a partisan, will soon eliminate what of his own is faulty, and adopt what he finds good in his neighbor's.

Partisanship is the bane of all true progress, and the differences of opinion seem so far to have tended in this direction. Especially is this true with regard to the advocates and opponents of the "new departure." Arguments give way to recrimination, assertions are made to stand for proofs. So startling is the assertion made by the adherents of this new school, namely, that "since the very day of the birth of dentistry its practitioners have been on a wrong scent, have been, and still are, ruining teeth instead of saving them," it is little wonder that amazement and indignation should have been the first feeling awakened, that wild assertion should have been met by as wild contradiction, and as wild counter-assertion. Just now the battle seems to be hushed, and the combatants are looking for results. The truth seems to be that, like all hobby-riders, the riders of this new horse drove him too hard at the beginning. What there was of good in their claims is not new, and what is new is not all good. At the bottom of their claims is the galvanoelectric theory, which has yet to be proved, and until this is done it would seem of little use to build theories or methods upon it.

Mechanical dentistry, which has so long held a subordinate place, seems now coming to the front again. New ways of working old materials, and new operations, are being constantly brought forward and claiming the attention of the best men. Of the new materials, celluloid is holding its own against vulcanite, and the controversy over the latter seems to have resulted in giving us a really valuable base. The "new mode" of working it promises to revolutionize its character and to render it, instead of an unreliable and poor material, one of the most useful in our possession, almost a new thing. Even vulcanite, which all thought had reached its climax, feels the impulse of this "new mode," and with it better results are reached than ever before. Continuous gum work, as it is called, consisting of a platinum plate, entirely covered on its buccal and lingual surfaces with a veneer of porcelain, imitating in its color that of the natural membrane, feels the boom, and better ways of making it and improved material have made it the fashionable base for whole sets of artificial teeth. The setting of "pivot teeth," formerly confined to the six front upper teeth, is now by new methods extended to the bicuspids, and even to the molars, enabling good roots to be saved and made useful that were formerly worse than useless, freeing the patient from the necessity of a plate. It is safe

to say, that by one or the other of these methods, more roots are now saved and made useful than at any previous period in the history of dentistry.

Hospital Practice and Clinical Memoranda.

EPIDEMIC CROUPOUS PNEUMONIA.

BY S. E. WYMAN, M. D. (HARV.), CAMBRIDGE, MASS.

THERE came under my observation, during the early part of March, 1881, two cases acute of croupous pneumonia in the same family and under such circumstances that I was led to think of the possibility of there being some causal connection between them, either in the way of a common local origin or of a direct contagion from the first to the second case.

A little boy aged five or six years, previously in perfect health, is suddenly attacked with marked symptoms of some approaching illness, namely, several attacks of vomiting, flushed face, furred tongue, and general debility. Cough, fever, and anorexia follow, with the subsequent development of a typical pneumonia of the upper lobe of the right lung. The physical signs are most pronounced; the attack runs a mild course, with moderately high temperature; defervescence, with the signs of beginning resolution, takes place on the seventh or eighth day. Convalescence is speedy and uninterrupted.

His mother, a delicate woman of twenty-eight or twenty-nine years of age, had not been well for several days previous to her son's illness. She had taken cold, and repeated examinations of her lungs gave evidence of a general bronchitis. She had recovered so as to be feeling quite well, when suddenly, just at the time when the pneumonia had reached its height in her boy's case, she was taken worse, and obliged to take to her bed.

By the way, she had occupied the same room in which the boy was ill during the day and night. Examination at this time gives the signs of a pneumonia of the lower lobe of the left lung. These signs were at no time pronounced, and in nearly every particular it was a typical case of croupous pneumonia. The symptoms were correspondingly mild, with the exception of obstinate vomiting, lasting thirty-six hours, which yielded to treatment. At no time was the temperature high nor the respiration greatly accelerated. The pulse was, however, rather rapid, 110 to 120, but of a good character, regular, even, and not intermittent. This then caused no uneasiness, especially as it was known that she had in health a very rapid pulse-rate.

One morning there was an improvement in all the symptoms, the temperature nearly normal, the number of respirations less, the pulse-rate diminished, and there were evidences that a corresponding improvement had begun in the affected lung. The patient was removed to another chamber, up one flight, during the afternoon. According to the nurse's account a change took place during the latter part of the night. Certainly this change was evident at the time of the morning visit, for the patient was pulseless, face cyanotic, with marked evidences of pain, breathing very much labored, and body bathed in cold sweat. Every effort was made to restore her, but to no avail, and she died in a few hours, with all the symptoms of a slowly-

forming thrombus in the pulmonary vessels. A post mortem confirmed the diagnosis of croupous pneumonia of lower lobe of left lung; it also showed a firm, undoubted ante-mortem clot, which started in the right ventricle and was continued through the pulmonary vessels down to those of very small dimensions. There was also a solidification of the lower lobe of the right lung, which was not diagnosed during life, although daily examinations of the front of both lungs were carefully made.

In the *Berliner klinische Wochenschrift* of October 3 and 10, 1881, in an article entitled Epidemic Croupous Pneumonia, are detailed the histories of forty-two cases of croupous pneumonia by Dr. Penkert, the physician who attended all the patients. These cases are all traced, either directly or indirectly, to local causes which seemed to be adequate for their production, at least to Dr. Penkert.

The epidemic was observed in Riethnordhausen, a little village of upwards of seven hundred inhabitants, situated in a hilly country, itself higher than any of the neighboring villages, and built on the slope of a hill. The part of the town of especial interest was situated lowest, in a valley running northeast and southwest, hills shutting it in on the northwest and southeast. In the most southerly part of this valley is the school-house, which had been built only four years, but was always damp; in this building the scholars of the middle and lower classes received instruction, and it was among them that the first cases were observed. Just to the north of, and close by, the school-house are two dwellings.

To the east of the school-house, and separated from it by a narrow street, is the new cemetery, which has

been in use for several years. Bordering upon and to the north of the new is the old cemetery, which is bounded further on the north by the church, which is built in a direction from east to west. Running along in the same direction as, and continuous with, the

church are stables, and, at right angles with the stables, the sheep-house of a neighboring farm. These buildings, the school-house and neighboring dwellings on one side, the church and stables on a second side, and the sheep-house on the third side, form roughly three sides of a hollow square, in which are the two cemeteries. Directly in front of these, and close up to their boundary wall, is a pool in which the water is still standing.

The school-room is in the corner of the building, with its windows opening on two sides, namely, to the east and south. The cemetery, laid out on filled land, containing much loose calcareous rock, has a very porous soil.

Although it is not rarely that the ground-water in the spring of the year reaches a high level, sometimes even flooding the surface, still the water has not stood so high in a long series of years as it did early in March of the present year. The highest point reached by the ground-water was observed on March 10th. Since, now, the water stood in the cellars of the houses situated on the highest ground, it is self-evident that the level of the ground-water in that part of the village immediately around the school reached a very high point. During this high water, as was easily to be seen from the then-existing level of the water in the neighboring pool, water stood in all the graves, and some of those which had been made during the preceding year fell in. This thorough soaking of the graves, subsequent to the falling of the ground-water, accelerated the decay of the corpses. The exit of the emanations, which carried with them the infectious material, was very much facilitated by the porous soil of the cemetery.

On the day when the water reached its highest point and on those immediately following, from March 10th to 12th, the weather was cloudy, with a barometric reading of 773 mm. (30.13 inches), a mean temperature of $+5^{\circ}$ R. (43.25° F.), and a prevailing southwest wind; from March 13th the barometer rose, so that it reached its highest point on the 16th, 790 mm. (31.1 inches), with a temperature of 0° R. (32° F.), and weather bright and clear. The ground-water fell. From March 17th the temperature rose, so that on the 18th to 20th the maximum temperature in March was reached, $+6^{\circ}$ R. (45.75° F.), a circumstance which was well calculated to influence the processes of decay. On the 22d the wind came from the northeast, but only the school-house and the neighboring dwelling were struck by this wind, since the remaining houses were protected from it by the sheep-house. The north-east wind, sweeping across the pool and cemetery, blows directly upon the school. In this way it is easy to suppose that the infectious materials, brought directly from the cemetery by the wind, penetrated the school-room through the opened windows and there caused the sickness. For the first cases occurred among the eighty-eight scholars of the two lower classes, twelve children being attacked during three periods, namely, March 27th to 29th four cases; April 2d to 4th four cases; and April 8th to 14th also four cases. The history of each of these cases corresponds with a sudden invasion of pneumonia, for in nearly every case the child, previously in perfect health, is attacked by vomiting, chills, headaches, pain in the side, and fever. The subsequent history and the accompanying physical signs warranted the diagnosis of croupous pneumonia. On the days immediately preceding the

above-named three periods there was generally a brisk northeast wind; on the intervening days the wind was generally in the opposite direction. Easter vacation occurred from April 13th to 25th, and during this time no new case of sickness was found among the scholars.

The spread of the epidemic took place partly among the brothers and sisters of those originally attacked, and partly through the association of the children and adults in other families. In all the forty-two cases it was possible for Dr. Penkert to ascertain the place of infection with tolerable certainty.

If we unite the cases which belong together ætiologically, then there were infected:—

(1.) At the original source, in the school, twelve cases.

(2.) Through three individuals, exposed to the same infection, but remaining healthy, four cases.

(3.) Through reproduction of the infectious material in the patients themselves and its direct transmission:—

(a.) Fixed as during the incubation period, five cases.

(b.) During the incubation period or the fully established sickness, nineteen cases.

(c.) After the end of the sickness, two cases.

As regards the probable duration of the incubation period, the facts justified Dr. Penkert in assuming this to be from five to eight days.

The ages of the children varied from one year and three months to twelve years; three adults, aged respectively thirty-seven years, forty years, and sixty years.

As regards sex there were twenty-seven females (twenty-four girls, three women) and fifteen males.

The seat of the pneumonia was:—

In 15 cases.....	inferior lobe of left lung.
In 16 cases.....	inferior lobe of right lung.
In 2 cases.....	upper lobe of right lung.
In 1 case.....	upper lobe of left lung.
In 1 case.....	upper and inferior lobe of right lung.
In 3 cases.....	inferior lobes of both lungs.
In 2 cases.....	whole right lung.
In 2 cases.....	not known.

The course of the pneumonia was light in thirty-three cases, and only nine cases could be called really severe, two of which ended fatally.

The duration of the attack until defervescence was:—

1 day.....	in 1 case.
2 days.....	in 3 cases.
3 days.....	in 3 cases.
4 days.....	in 9 cases.
5 days.....	in 3 cases.
6 days.....	in 8 cases.

— As far as known, the first dentist in this country was Josiah Flagg. He held a major's commission in the American Revolutionary Army, and began to practice dentistry at the close of the war. An officer under Count Rochambeau taught Flagg while the two armies were quartered in Rhode Island. Later he practiced in Boston, and during the last war with England he was taken as a prisoner to England, and while on parole made the acquaintance of Sir Astley Cooper, and worked with him in Guy's Hospital.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

M. H. RICHARDSON, M. D., SECRETARY.

MORAL INSANITY.

MEETING OCTOBER 3, 1881. DR. JELLY read the regular paper on Moral Insanity. Vide page 560 this Journal.

DR. BOWDITCH said that the paper was a very interesting one to him, and that it suggested certain thoughts with regard to our mode of discipline in insane cases; whether there cannot be more regular and severe discipline. In the first case reported by the reader the discipline of the House of Correction cured the man after three previous commitments to an asylum, where there was no such discipline. Most of us would call two or three of these cases devils incarnate. The last case seems to be very suggestive of a youth badly born and educated, without proper parental discipline. We are beginning to think that tender care is necessary in the treatment of such men as these, even if they perform the most atrocious acts. More evils follow false philanthropy than the hanging of a morally insane man.

DR. COWLES said that in the last case reported he felt that there was some degree of impairment of the intellectual faculties. The man also seemed to have become, in a certain way, expert in indulging his propensities in annoying people and causing them trouble. To create sympathy for himself he sometimes feigned the intention to commit suicide, and practiced various devices and means to gain his ends. There is one interesting feature of these cases, brought out by Dr. Ray, which illustrates their morbid perversity. He mentions a person who could talk beautifully on various good topics, but nevertheless would constantly annoy people about him, his acts being at variance with his professions. Dr. Ray asked him why he did so. The patient replied that he knew the difference between right and wrong, that he knew his acts were wrong, but that he enjoyed doing them. This case was cited as a peculiar one, illustrating the great difficulty in drawing the line between moral depravity as a part of the character of a man and that moral depravity resulting from disease. With regard to the causes of moral insanity, they vary greatly. In one case there was a strong hereditary taint—father, grandfather, and other members of the family, all committed suicide. The patient was afraid of doing the same thing himself. He was a man of marked peculiarities of character, with alternations of good-fellowship, and moroseness and unsociability, being often unpleasant to those about him. Sometimes these peculiarities were more marked than at others. He was sent to an insane asylum, where he was a very troublesome patient. He was discharged after a few months, but for some years he continued in a morbid state, finally recovering sufficiently to be able to transact business. There is no doubt but that a cause which operates largely in the production of moral insanity is defective education of the young. In two cases there was distinct history of youth spent in habits of self-indulgence, uncontrolled by relatives or parents, and untrained in anything like good habits. Both were persons of exceptional ability.

DR. GOLDSMITH, of the Danvers Asylum, said he had seen very few such cases, in fact but one, in which he could detect no impairment of the intellectual faculties. He had, however, seen cases where the intellectual impairment was so slight as to appear an unimportant feature of the disorder, not being sufficiently marked to prevent the patient from living in ordinary relations to society. These latter cases are very trying and unsatisfactory to treat in asylums, as they are very shrewd in planning and executing mischief, and cannot be controlled without a more vigorous surveillance and discipline than is contemplated, or allowed, in asylum organization. The change of form of mental disorder, which Dr. Jelly describes in one of his cases, appeared to him a very important guide in distinguishing whether or not bad conduct be a part of the manifestations of mental disease. Dr. Jelly says that the young man would have a period of unusual depression and inactivity, then one in which he would appear ordinarily cheerful and well behaved, and finally would become restless, active, and prone to various vicious practices. Dr. Goldsmith knew of no explanation for these changes, unless they be regarded as the results of disease, and the case appeared to present all the features of *folie circulaire* in miniature.

DR. CHANNING said that moral insanity is a convenient name which applies to certain symptoms. It seemed to him a great question whether there is such a disease. Sufficient observations have not been made to warrant the use of such a name. In such cases there exists generally a certain amount of intellectual disturbance. At Auburn there were a number of cases of this kind which were morally insane. Some of these were found to have disease of the brain, epilepsy, etc. Several of these were called moral insanity.

DR. JELLY remarked that he meant to have said in the cases reported that intellectual impairment was not a prominent symptom.

DR. INCHES said that he was strongly impressed with the remarkable success achieved in one of the cases recorded, where, by the refusal of the judge to listen to the sworn affidavit of two alienist physicians, the patient was sent to prison, whence, after undergoing the required discipline with daily work at a trade, and a comparatively short detention, he was, at the expiration of his sentence, discharged cured, and remains so since, holding a responsible financial position, his special form of insanity having been kleptomania and dissolute conduct. Dr. Inches thought that the lesson to be learned from this case was an improved arrangement of our asylums by which such patients can be subjected to regular discipline and daily labor. He suggested that a committee be appointed to look into the matter.

DR. JELLY thought the number of cases of the kind which he had described too small to require a separate institution, or even a separate ward. While of the opinion that more discipline and hard labor might be the proper thing to do in these cases, he should feel it his duty not to enforce it.

DR. C. F. FOLSON said of the second case described by the reader of the paper (which he did not consider one of moral insanity) that he had been placed in an uncomfortable ward of a State asylum and had been finally told that he must stay there until he could behave himself at liberty, which he finally concluded to do; in other words, he gave up his wicked habits as soon as it was found by him decidedly for his interest

to do so. Dr. Folsom did not think insane asylums could be so conducted as to be fit places for such persons, who really needed punishment and nothing else. They are to be found in large numbers in our reform schools, our industrial schools, and our prisons (where they belong), and constitute a large portion of the inmates of these institutions. Moral insanity undoubtedly exists, but, except in very rare instances, it is combined with disorder of the intellect, which could be recognized; although uncomplicated with other forms it is an exceedingly uncommon type of insanity, and is often confounded with simple depravity, different persons differing in opinion, as they probably always will, in regard to the amount of responsibility attaching to individual cases. One of the most common and striking diagnostic marks of moral insanity is periodicity, there being, as a rule, intervals of self-control and good conduct, even in its later stages. In dipsomania, for instance, one of the forms of moral insanity, the impulse to drink is sudden and uncontrollable, and very often at the last time that the sufferer would be likely to give way to his passion if he could resist it, in contradistinction to debauchery, where there is preparation for the excess, or to softishness, where there is a steady and progressive brutalizing of the individual, and blunting of the mental capacity and moral sense. The Pomeroy murderer was mentioned as a case in which moral insanity and epilepsy both were testified to at the time of the trial, but Dr. Folsom had watched the young man since his commitment to prison (six years), and neither he, nor the prison physician, nor the officers had observed any indication of either epilepsy or moral insanity, while his behavior had been exceptionally and uniformly good, as soon as he learned that he must be punished if it were not so. If epilepsy or moral insanity existed, Dr. Folsom did not believe either could be concealed without treatment for six years and, therefore, thought now, as he did at the time, that the court was right in declaring the young man guilty of murder, although his sentence to be hanged was commuted by the government to imprisonment for life in a separate cell.

Recent Literature.

A Manual of Histology. Edited and prepared by THOMAS E. SATTERTHWAITHE, M. D., in association with Drs. Thomas Dwight, J. Collins Warren, Wm. F. Whitney, Clarence J. Blake, and C. H. Williams of Boston; Dr. J. H. C. Simes of Philadelphia; Dr. B. F. Westbrook of Brooklyn; and Drs. E. C. Wendt, A. Mayer, R. W. Amidon, A. R. Robinson, W. R. Birdsell, D. B. Delavan, C. L. Dana, and W. H. Porter of New York city. New York: William Wood & Co. 1881.

In view of the demand for a concise manual of histology which should represent our present knowledge of the science, Dr. Satterthwaite, with the assistance of the gentlemen named in the title, have produced the above book. It is divided into twenty-eight chapters, the first nine of which were written by the editor himself. In speaking of the requisite materials and their use, he wisely omitted the subject of optical principles, which form so prominent a feature of many of our histological manuals, and which are much better treated of usually in any of the standard text-books of physics.

The chapter on the blood is especially good, and we would heartily endorse the cautionary remarks made

on measurements of the red corpuscles in man and animals. Epithelium and the tissues forming the connective substance group are treated very thoroughly in four chapters. Then follows a good description of the teeth, and a long chapter on the general histology of the nervous system. This first part is marked for evenness of style and clearness of expression, and in it are embodied original observations.

The tenth chapter, on muscular fibre, is by Dr. Dwight, who presents the results of some original researches.

Blood-vessels are next discussed by Dr. Wendt, who expresses his belief in the *physiological occurrence of endothelial desquamation*, as he explains the *interecalated areas* of Auerbach, and the bodies hitherto known as microcytes, hamatoblasts, etc.

Dr. Birdsell gives a very satisfactory chapter on the lymphatic system.

The liver and biliary apparatus, together with the kidney, are discussed in two chapters by Dr. Mayer, who has made a careful study of them, and, among other things, makes a positive assertion that the bile-capillaries are provided with walls of their own.

The two chapters on the male and female generative organs were written by Dr. Simes, who does not attempt to settle disputed points by means of personal observations, though the subject is presented very well.

Dr. Westbrook has written the chapter on the respiratory tract, and given the essential details very satisfactorily.

The chapters on the skin by Dr. Robinson, and the central nervous system, by Dr. Amidon, are long and exhaustive, and deserve a careful study.

The chapter on the eye, by Dr. Williams, and that on the ear, by Drs. Whitney and Blake, are well written, and present the histology of these parts very well indeed.

Dr. Delavan on the nasal fossae, pharynx, and tonsils, and on the mouth and tongue, has done some good work.

The alimentary canal, the urinary excretory passages, suprarenal capsules, and the mammary gland, are treated in three chapters by Dr. Wendt, who has presented his subjects very clearly. He considers that the evidences of destruction of the epithelium in the secretion of milk are not positive and convincing.

Dr. Dana is the author of the chapter on the spleen, pancreas, thymos, thyroid and pineal glands and pituitary body, and gives all the essential points in the histology of these bodies.

The thick cutis vera forms a separate chapter, written by Dr. Warren, who details his discovery of the fat-columns.

A third of the illustrations in the book are original, and all are very well executed. The type is large and new and the typographical errors remarkably few in number.

In conclusion we may say that we consider it without question the best book on the subject in the English language.

— Von Arlt, the professor of ophthalmic surgery in the University of Vienna, would, on completing the seventieth year of his age in April, 1882, have retired in accordance with law, but has been requested by the Minister of Instruction to remain in office until the end of the academical year in 1883, and has accordingly withdrawn his notice of resignation.

Medical and Surgical Journal.

THURSDAY, DECEMBER 15, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

THE GARFIELD MEMORIAL HOSPITAL.

THE movement set on foot in Washington, some weeks since, to establish this institution, has so far met with but indifferent success. Already has the reaction set in from the feverish excitement attendant upon the sufferings and death of our late President, and our sympathies are no longer so easily aroused. The mourning has been removed, and it is with even a little impatience that we find late issues of some medical journals still discussing the wound, the treatment, and medical attendants. *Le roi est mort; vive le roi!* Well, this is, perhaps, one of the healthiest and happiest tendencies with which man can be endowed, but we have not yet done with all feeling; the trial of Guiteau is now progressing in a crowded court-room, and we cannot foretell how far the plea of insanity will be recognized, nor where or to what lengths this trial will proceed. Congress has yet to assemble, publish its memorial volume of addresses, and vote a few thousands of dollars for a fitting tribute to the memory of the late President of the United States.

What shape shall this tribute take? and would not the memorial hospital most humanely, most beneficently, and most lastingly perpetuate his memory and our appreciation of his martyrdom? These are the questions which it would be well to consider.

Washington is already a city of monuments and statues, good, bad, and indifferent, very few of merit, very many costing far more than their materials will ever bring at second-hand prices; as objects of art they would probably have no bidders, and none appreciate this more than Washingtonians themselves; but through and around all this adornment of parks, statues, and monuments the poorer classes may wander at will, admire the engineering skill which lifts huge blocks of stone to the dizzy height of the half-finished shaft to Washington's memory, which has already taken so many years to become half finished, and endeavor there to obtain employment, and eke out their scanty portion of this world's goods. With many, however, must arise the thought, What if sickness or accident comes,—what then? The poor-house and work-house hospital, a bed of pain in an unhealthy location, in the midst of thieves and prostitutes; and that is the City Hospital. Are there then no other hospitals? Yes, there are; one, an accident hospital, recently established, well conducted, with an excellent corps of attending physicians, but very limited in its

means and accommodations, struggling for existence; then there is Providence Hospital, where your poor man may so influence the sister in charge as to obtain admission, but he has no right there simply as a resident of the District of Columbia. Certainly, you perhaps query, the hospital staff of medical men would see that he be readily admitted? Their power, unfortunately, is limited, as they themselves hold their positions at the will of the sister in charge, and thereby hangs a tale which has already been told by a number of able and prominent physicians who *once* constituted the medical staff. There remains the Freedman's Hospital, created by a kind and fostering government for that race whose sudden relief from bondage brought this welcome burden upon our government, but it is and should be kept for them. Luckily there exists in the Children's Hospital suitable accommodations and care for the relief of the suffering little ones, and in the Columbia Lying-In Hospital proper care for delicate women. In the face of these naked facts, what profits, in the mind of the poor man, lost in the practical, in the necessities of to-day, all your devotion to magnificent distances and correspondingly magnificent structures? A commanding shot tower would look far lovelier in his eyes than Washington's shaft, for the shot tower would indicate a manufactory where work could be obtained, and where care for the sickness of the workmen could be reasonably presupposed.

But this project for a memorial hospital does not appeal alone to the pauper class. Washington is filled during the session of Congress with those who lead a hotel and boarding-house life,—legislators, and office and amusement seekers,—many of whom seek and find an entrance into society; and the freedom with which wine is used at dinners and suppers, to those unaccustomed to such a life, and to the restraints which refined society imposes upon those to whom she seems to give most freedom, or to the broken-down man of business, soured with the world and seeking employment at the clerk's desk, results in many an attack of so-called *malaria*, for which Washington is of late becoming quite too notorious. For such cases, when they pass into a condition requiring temporary restraint, there is no other resort than the insane asylum, and comment upon this fact is unnecessary.

A due regard for the æsthetic can, moreover, be readily engrafted upon the memorial hospital plan. A well-built, ornamental administration building, as a centre for the modern hospital wards, with prettily laid-out grounds, and adorned with an allegorical statue, if one likes, and with mementoes of Garfield and his martyrdom, in a healthy, commanding situation, would give ample room for the display of the artistic and beautiful.

The interest which Mrs. Garfield has expressed in the project by her published letter, which Secretary of State Blaine has taken by his personal efforts, and which United States Treasurer Gillfillan has shown by accepting the care of the subscription funds, should be enough to stamp it as a national movement, and the present uncertain state of the project should be attrib-

uted to the fact that sufficient time has not yet elapsed in which to make a proper appeal to our people. There is always some hesitation in making subscriptions of any amount, as so many projects have been started, subscribed to, failed, and the collected funds gone no one knows where; certainly not back to the original subscribers in many cases. This can be readily avoided by putting the matter on a proper basis, and securing guarantees from responsible custodians for the return of the money in the event of failure.

GEORGE ELIOT AS A MEDICAL NOVELIST.

SINCE George Eliot's death, the usual posthumous accession of fame has come to her. Every magazine of literary pretension has contained its article, more or less discriminating, in regard to her. Many of these notices have dwelt at length upon the accuracy with which she described the daily lives and emotions of the different classes of people of whom she wrote. Her stories of clerical life were at first considered evidently the work of a clergyman. Her country scenes in her early stories were so faithful a description of the village in which she had passed her girlhood that the place was recognized, and it seemed absolutely certain that they were written by some resident. A man was fixed upon as the only possible author, and seems to have been himself persuaded by his friends that perhaps he was in some mysterious way the writer of the stories in question. It is claimed that a practical carpenter can find no fault with Adam Bede; his work is as well described as if done by a man bred to the bench; and of Daniel Deronda it is said that it shows a fullness of knowledge in regard to the Jews which even a Hebrew of the Hebrews might envy but scarcely hope to excel.

The crowd of notices of this singularly gifted woman have already nearly ceased, and we have watched in vain for some similarly appreciative remarks upon her medical characters. The industry with which she studied Jewish history and clerical character must have been almost equaled by the fidelity with which she applied herself to medical history and traditions.

It is natural, perhaps, that the faithfulness of her medical portraits should be less widely appreciated than other, but so far as the present writer has seen, it has been entirely unmentioned. Leaving out of view other characters, *Middlemarch* is the story of a physician, young, enthusiastic, proud, and self-reliant, well educated in his profession, but with little practical knowledge of the ways of getting bread and butter. His small inheritance nearly exhausted by the expenses of a Parisian education, he is dependent upon his profession while bent upon doing many things, highly praiseworthy from a scientific point of view, but not specially calculated to secure a good income. He goes into a country town where he excites the jealousy and hatred of the older practitioners, adds to his burdens by a marriage that proves uncongenial, becomes involved in suspicion over a case that terminates unfortunately, and ignominiously fails. Many of the

matters involved are so purely English that it is hardly possible for an American to judge of them, but the young doctor's experience, on the whole, contains much that is common in the life of most young physicians who are obliged to make their own way in the world.

Now, doctors figure in novels frequently enough, though they are generally the dimmest of shadows so far as their professional character is concerned, and many an otherwise good novel is completely spoiled for a medical reader by the author's exhibition of profound ignorance of everything pertaining to medicine except popular superstitions. The really good physicians of novels, with whom the living physician sympathizes, might almost be counted on the fingers.

George Eliot's Dr. Lydgate talks and acts as a medical man would do; he makes grave mistakes in dealing with brother-practitioners and ignorant patients, but they are natural mistakes for an untried physician of his temper, and the medical reader finds nothing improbable. Lydgate is undoubtedly, something of a prig, fond of comparing himself with great men whose lives are landmarks in medical history; ambitious above all to contribute something toward enlarging and strengthening the firm scientific basis of his profession, and to do so he would "keep away from the range of London intrigues, jealousies, and social truckling, and win celebrity, however slowly, as Jenner had done, by the independent value of his work."

Authors seldom attempt to follow physicians in their intercourse with their fellow-practitioners, for medical etiquette is a fearful thing to the laity, even at the present day. Lydgate's first complication with a medical brother is too matter-of-fact to be a work of the imagination. Fred. Viney, ailing for a few days, called in his regular attendant, Mr. Wrench, who found no well-marked symptoms, made general remarks about his being run down, and departed, sending round later certain powders, whose contents proved black and drastic. Next day the patient sat and shivered by the fire, and was evidently worse. Mr. Wrench, not appearing, was summoned, and was found to be away in a neighboring village; piqued at the neglect, and anxious about her boy, Mrs. Viney discusses the propriety of calling in another physician, and finally calls Dr. Lydgate. Dr. Lydgate listened to the mother's story, a narration in which Mrs. Viney insisted on every point of minor importance, especially upon what Mr. Wrench had said and what he had not said, and on examination of the patient found little difficulty in recognizing typhoid fever. He promised to write to the regular attendant, and, at the request of the mother, to meet him in the evening. The family was an important one, and he was naturally anxious to make a good impression, and, worse yet, he had seen Louis, and followed his demonstrations of the difference between typhus and typhoid, and, naturally felt somewhat superior to his elder brother on the subject; his manner in consequence was not specially conciliatory; the impolitic words of the self-important father, who was elated with recent political success, complicated the situation, and the sensitive

Dr. Wrench declined further attendance. Lydgate, with many regrets, but with a clear conscience, entered upon the full charge of the case, and at the same time upon troubles which ceased only with life itself.

It is by no means our desire to follow the course of Lydgate's series of mistakes and misfortunes, but simply to express our admiration of the genius that created him, and our appreciation of the sympathy manifested for the trials of a high-minded physician, and of the difficulties that beset his path.

It is perhaps needless to say that the story is a sad one, George Eliot's books have always an element of sadness; the picture of Lydgate's failure is so forcible and so life-like, it might so well be the biography of an actual physician, that one reads it with a feeling of actual bitterness.

The study bestowed upon the medical portion of the book we have already alluded to; it must have been prodigious, to borrow Dominic Sampson's favorite expression, — study of books, very evidently, but study of men also. It is evident that she had at some time in her life opportunities of watching very closely the sayings and doings, and even the manner of thought, of medical men.

Undoubtedly much of this study was done during the five years that intervened between the production of *Felix Holt* and *Middlemarch*. It was evidently, however, much more than a magnificent piece of cram. Much of her insight into the peculiarities of country practitioners was, without much doubt, the result of her girlish observation in her native town. Her study of physicians also included their patients and their afflicted families. The sympathizing relatives of one of Dr. Lydgate's patients afford Milner Fothergill a text for a long dissertation on nurses in one of his entertaining letters from England.

Many of the wise sayings might well be quoted: we have room only for a single quotation, which reads like a commentary on recent events: "Beware of too great readiness at explanation; it multiplies the sources of mistake, lengthening the sum for reckoners sure to go wrong," and "Even Lydgate's proud outspokenness was checked by the discernment that it was as useless to fight against the interpretations of ignorance as to whip the fog."

It is by no means the intention to add a moral, but the story of a faithful but unsuccessful life is fittingly closed by the closing words of the story originally applied to other characters of the book, "The growing good of the world is partly dependent on unhistoric acts, and that things are not so ill with you and me as they might have been is half owing to the number who lived faithfully a hidden life, and rest in unvisited tombs."

— A medical work, on an obstetrical subject, written in Italian and English, and very handsomely illustrated from frozen sections, fell under our eye the other day. On the title-page we found the following in Italian: "*Evoluzione Spontanea Sorpresa in Atto Mediante La Congelazione*," which was thus rendered into English: "Spontaneous Evolution Caught in Act through Corpsy Congelation."

OBITUARY: DR. THOMAS B. CURTIS.

WITH deep regret we have to record the sudden death, at the early age of thirty-nine years, of a very valued member of the editorial staff of the *JOURNAL*, Dr. Thomas B. Curtis. Dr. Curtis' connection with the *JOURNAL* in an official capacity had not been of long duration, and a recent absence from the country of several months had still further limited his immediate contributions to our editorial department, but his varied knowledge, good judgment, and really extraordinary learning in medical literature have always been freely at our disposal, and when he did take up his pen, what he wrote was always sure to be attentively read.

It is in the records of the Proceedings of the Boston medical societies, as they have appeared during the last six or seven years in the pages of the *JOURNAL*, that Dr. Curtis' name has become so familiar to our readers, and it is in these records that it will be so greatly missed in the future.

In the next issue of the *JOURNAL* we shall endeavor to give some details of the life of a man who, though young, was already remarkable, and who, had he lived, we think it may without exaggeration be safely said, would certainly have been very distinguished. To-day it is our duty simply to record the loss of a dear colleague.

MEDICAL NOTES.

— It is thought in some quarters that the quarantine establishment at the port of New York should be made self-sustaining, and testimony is now being taken before a committee of the State senate with a view to the practicability of attaining such an end. The fees of the health officer of the port now amount to between thirty-six thousand and thirty-seven thousand dollars per annum after deducting all expenses.

— A medical man in Toronto asserts that the results of the investigation made of several deaths of school-children which came under his observation were due solely to a too close application to books by scholars of nervous temperament and weak constitutions. He protests against a course of study so severe as to compel pupils, in order to keep up with their classes, to apply themselves to their books outside of school hours.

— At a late meeting of the Pathological Society of London, the president showed an ear of corn discharged through the chest. He saw a child with Dr. Massey, of Chamberwell, suffering from an abscess over the left supra-scapular region, the skin over it feeling boggy. No evidence of effusion of the chest. A grooved needle was passed in, and a puff of air and pus came out. Free suppuration occurred, and after a time an ear of corn was passed, and then the wound healed. On inquiry no history of how or when the ear got into the lung could be obtained; the child had not been ill. No doubt the ear of corn had been inspired. Watson mentions several cases of such bodies passing into a bronchus, but all ended fatally. A

similar case has recently been recorded in America, but with this exception Dr. Wilks knew of no other such case terminating in recovery. Dr. Goodhart remarked on the frequency with which foreign bodies get into the bronchi without causing acute symptoms. He had twice found gangrene of the lung associated with the impaction of a piece of bone in a bronchus, which had not excited any notice at the time of its inhalation. Mr. N. Moore suggested that the ear of corn should be referred to a skilled botanist, because possibly it was a species capable of a spiral movement, by which it worked its way to the surface. Mr. Eve mentioned a specimen, in St. Bartholomew's Hospital Museum, of an umbrella ferrule in the bronchus and abscess in the lung, in which there was no history to show how or when this large body entered, and the case had been regarded as one of simple phthisis.

— In his report of the Paris Night Service, for the quarter ending September 30th, as published in the *Gaz. des Hôpitaux*, Dr. Passant states that there were 1687 visits paid, or 18.3 per night. Of these, 676 (40 per cent.) were paid to males, 837 (50 per cent.) to females, and 174 (10 per cent.) to children under three years of age. Of these visits, 149 were for croup or other laryngeal affections, 201 for various affections of the lungs and heart, 369 for gastro-intestinal affections and other diseases of the abdomen, 11 for strangulated hernia, 13 for retention of urine, 114 for metritis, metrorrhagia, and miscarriage, 117 for labors, 393 for cerebral and other affection of the nervous system, 10 for insanity, 25 for alcoholism and delirium tremens, 24 for rheumatism, 49 for eruptive affections, 25 for typhoid fever, 89 for external or internal hemorrhage, 81 for wounds and contusions, 27 for fractures, dislocations, and sprains, four for burns, 13 for poisoning, two for asphyxia from charcoal, four for drowning, four for suicides. In 41 cases the patients were dead before the practitioners could reach them.

CHICAGO.

— The County Commissioners of Cook County have voted to turn over a part of the County Hospital to the homoeopathic profession, and have agreed to appoint seven homoeopathic physicians to attend to the work and to be known as the homoeopathic medical board, in contradistinction to the present board, whom the commissioners do not propose to disturb. Of the seven physicians to be appointed, the privilege is given to each of the homoeopathic colleges to nominate two. The remaining three will be elected by the board of commissioners without any nominations. One of these colleges has recently occupied its new building directly across the street from the hospital.

— As was expected, the cold weather has brought an increase of small-pox. It is breaking out in unexpected places and under remarkable circumstances. There must be a marked susceptibility to the disease on the part of our people. The health department has just restricted the west division (the largest) of the city, and has got a larger force of inspecting physicians. The work of vaccinating all the people in the neighborhood of cases of the disease is being

pushed, if possible, with more vigor; and renewed exertion is being made to compel those who have the care of cases of small-pox to keep in their houses and off from the streets.

Miscellany.

NINTH ANNUAL MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION AT SAVANNAH.

SECOND DAY'S PROCEEDINGS.

THE morning session opened with the election of new members and the appointment of various committees.

DR. J. J. SPEED, of Kentucky, read the first paper, on

INSIDE SOURCES OF DISEASE.

Proper attention to the stomach and appetites was urged as more important than external sanitary influences.

DR. A. J. MILES, of Ohio, presented a paper on

HISTORY OF SUNSTROKE MORTALITY IN 1881.

He stated that the total mortality rate per thousand in Cincinnati rose from an average during the past ten years of 181.77, in the months of July and August, to 280.99 in the same months of 1881; an excess of 99.22 per cent. The severest of the epidemic was from July 7th to 15th. The total mortality was 288; 95 were of American birth, nine colored. Only those deaths reported as directly from sunstroke were considered. With regard to the influence of humidity it was noted that 233, or 91.32 per cent., deaths occurred when the range was below 60, and that on cloudy days there were only 129 deaths, or 44.72 per cent. More than nine tenths of the mortality was on days when the air was dry; an observation contrary to generally received views. A marked decrease in the death-rate was obtained by erecting temporary hospitals all over the city, thus avoiding transportation. A clinical history of some cases was then given, showing that there were three distinct varieties of symptoms: (1) marked congestion of the brain, with bounding, incompressible pulse, and often convulsions; (2) somewhat similar to the above, except that the heart's action was very weak; (3) complete collapse. Immediate treatment was directed both to the extremely high temperature and the heart, the remedies and methods being those adapted to the same symptoms under other conditions.

DR. J. F. A. ADAMS offered the next paper, upon

MALARIA IN NEW ENGLAND.

Considering the period of prevalence, he said the disease was endemic for an indefinite period subsequent to clearing off the forests, then, disappearing entirely, it occasionally reappeared as an epidemic, lasting a few years. Since 1850 there have been a few cases always to be found in a low swampy region near New Haven, and from this district, in 1864, the disease began a northerly course through Connecticut, following the rivers, in 1877 crossing into Massachusetts, and penetrating to the extreme northwestern border of

the State. More than three fifths of the cases have been in Springfield, West Springfield, Holyoke, and Chicopee, cities near each other, two on the east, and two on the west bank of the Connecticut River. In high and dry places the disease has been rarely seen, as it follows directly up the rivers. The largest number of cases was found where there were swampy, muddy banks subject to periodical overflow, and, except these places, reservoirs for water-power were the most fertile sources of the poison, probably because large tracts of land, overflowed in the spring, were exposed as the ponds were drawn down during the summer; in fact, there seemed to be a direct relation between the amount of swampy bottom thus exposed and the prevalence of malaria. Eleven of the eighteen towns reporting more than six cases were in Hampden and Hampshire counties, and the remainder in Berkshire County, either near reservoirs or swamps. The disease did not advance steadily, but attacked places long distances apart, and subsequently the intermediate towns. With regard to the relation between malaria and typhoid fever, the reader found that, as malaria increased, typhoid decreased in the infected districts. He estimated that there were fewer cases of malaria this year than in 1880.

HON. ERASTUS BROOKS, of New York, offered a paper upon The Duties of the Citizen to the State in maintaining Public Health, showing the importance of individual aid in warding off contagious and infectious diseases.

AFTERNOON SESSION

a paper by DR. ALBERT C. GORGAS, U. S. N., on The Pernicious Effects of Tobacco on Youth, was read by title only.

DR. ISAAC JONES, of Pennsylvania, read a paper on School Hygiene.

The paper of DR. LOUIS A. FALLIGANT, of Savannah, upon Fraternity among Scientists, was read by title.

DR. C. B. WHITE, of New Orleans, presented a paper on

THE YELLOW FEVER EPIDEMIC OF 1878.

He stated that there was a preponderance both of the mortality and of the cases of adult males as compared with females. From an analysis of thirteen hundred fully reported cases he concluded that the actual greatest mortality was among four-year old males; that after that age the per cent. of recoveries was proportionally larger; that from seven to eleven years the death-rate was nearly uniform; that the smallest number of cases and deaths in 1878 was found at the age when the protecting influence of the epidemics of 1867 and 1870 would be most felt. He advanced no thoroughly satisfactory reason for the greater mortality of four-year old males.

The next paper was by DR. A. R. WRIGHT, of Buffalo, on the Probable Cause of an Epidemic of Diarrhoeal Diseases in Buffalo, N. Y., in August and September, 1881.

DR. MOSES T. RUNNELS, of Indiana, followed with a paper on Impure Water and its Dangers.

DR. F. PEYRE PORCHER, of South Carolina, and DR. J. D. GATCH, of Indiana, representing the governors of their respective States, addressed the Association.

DR. L. C. DUNCAN, of Illinois, read by title his paper, The Atmospheric Element in Local Epidemics.

EVENING SESSION.

The first paper of the evening session was by DR. S. S. HERRICK, of Louisiana, on Railroad Sanitation. He urged the employment of experts to examine employees for physical defects.

DR. B. JOY JEFFRIES, of Massachusetts, gave an interesting lecture on Control of Defective Vision on Land or Sea, illustrating his remarks by practical experiments.

The last reader of the day was DR. ALBERT L. GIBSON, U. S. N., on Health the True Nobility. He advanced the usual suggestions as to the necessity of pure air, good food, and cleanliness.

THIRD DAY'S PROCEEDINGS.

DR. DANIEL M. BURGESS, of Havana, read upon PRACTICAL EXPERIENCES IN REGARD TO THE INFECTION OF VESSELS WITH YELLOW FEVER AT THE PORT OF HAVANA.

As a result of his investigations it appeared that vessels may become infected in the harbor of Havana; that they may carry the infection; that they are usually infected at and near wharves or near infected vessels in regard to locality; that under such circumstances they may become infected at any season of the year; that the crew may carry the disease abroad; that to sugar, tobacco, and baggage the germs of the disease may adhere, and thus infect the crew and vessel; and also that vessels may enter the harbor of Havana at any season of the year, discharge their cargoes in the open bay, removed from any infected vessel, permitting none of their crew to go near the shore, and sail away uninfected and dangerous to no port that they may enter. The disinfecting of vessels by sulphur and sulphate of iron he considered entirely satisfactory in preventing the development of the disease after leaving the harbor.

Reports and the appointment of committees closed the morning session.

DR. EZRA M. HUNT, of New Jersey, opened the evening session with a paper entitled The Sanitary Significance of the International Medical College.

EDWARD FENNER, Esq., of New Orleans, read a paper on the New Orleans Sanitary Association.

Papers by DR. H. B. HOOLBECK, of South Carolina, on Scarlet Fever as it affected the White and Colored Races in Charleston, S. C., in the Spring and Summer of 1881, and by DR. R. B. S. HARGIS, of Florida, on Prevention of Diseases of Infants commonly ascribed to Dentition, were read by titles only.

(To be continued.)

A CURIOUS ENDEMIC ON BOARD THE NELLIE SWIFT: WAS IT BERI-BERI?

MR. EDITOR.—In reading your valuable journal of October 27th last, I noticed a paper, read before the Suffolk District Medical Society, entitled A Curious Endemic. It was certainly curious. I can see no similarity in the cases described by Dr. Shattuck and trichinosis as suggested by Dr. Gannett. As Dr. Shattuck indulged in the hope that some reader might be able, either by experience or reading, to throw some light upon the source or nature of the disease, I will, from reading, respectfully refer him to the disease known as beri beri, a disease very common in India,

Hindustan, Ceylon, and other parts of Southern Asia. Dr. Shattuck will find his cases described very fully in Aitken's Science and Practice of Medicine, page 116, second volume, under the heading of Beri-Beri, or the Bad Disease of Ceylon.

Yours most respectfully,

J. F. COSTELLO, M. D.

VEVAY, INDIANA, November 10, 1881.

MR. EDITOR,—At the same time that I heartily thank your valued correspondent for his suggestion as to the true nature of the cases reported under the head of A Curious Endemic, I regret that I cannot adopt his view. It is true that the sickness which befell the unfortunate crew of the Nellie Swift bears a certain clinical resemblance to mild cases of the disease known in India, Ceylon, etc., as beri-beri, in Japan as kak-ke.¹ Some recent German writers think this disease to be an endemic pernicious anemia, as it were; and of late the attention of the medical world seems to have been somewhat widely awakened to its consideration. In the summer of the year 1880, the first and only cases of the disease ever observed in this country were admitted to the Marine Hospital in San Francisco from a Brazilian ship-of-war. A report of these cases is promised in the forthcoming volume of Marine Hospital Reports, and cannot fail to be interesting reading. It is stated that the surgeons of this ship-of-war protested before she left Brazil on her cruise that she was not properly provisioned for so long a voyage, and that the quarters were very deficient from a hygienic point of view. The ship sailed for Europe, touched at various points in the Spanish Peninsula and in the Mediterranean, passed through the Suez Canal to Aden, where the disease first appeared, and gradually worked her way to San Francisco. In the Pacific Ocean a great deal of rainy weather was encountered, with much of the time intense heat. An idea of the provision in the ship for the health of the crew may be gathered from the fact that the infirmary was in the bows of the ship, had no ventilator, and was so dark that a lamp was required in the daytime to see the patients.

It is more than ten years since it became at all generally known that beri-beri is far from uncommon in some parts, at least, of Brazil, and I have dwelt on these cases reported from San Francisco in some detail, first, because they are the only cases ever known to have occurred in the United States,—or even North America; and secondly, because their apparent etiology agrees precisely with that assigned to the disease by competent observers in India, Ceylon, Java, Japan, etc., all of whom lay special stress on air vitiated by great swamps or other causes, poor and insufficient food, and prolonged exposure to wet and damp.

Now the crew of the Nellie Swift came from regions in which neither beri-beri nor any disease resembling it has ever been known to occur; the provisions and quarters were quite as good as is usual on Bank fishermen; no great hardships were encountered, and the outbreak of disease which we described stands absolutely alone, as far as can be ascertained, in the annals of the nursing fleet. In short, the entire absence of the exciting causes which all those who have studied the disease are agreed in assigning as productive of the same, and the fact that the affection has hitherto been

strictly confined to tropical and semi-tropical countries, draw a wide distinction between beri-beri and the "curious endemic" of the Nellie Swift.

Yours very truly, F. C. SHATTUCK.

December 6, 1881.

THE VIVISECTION PROSECUTION.

To those aware of the actual facts of the case, the result of the magisterial inquiry into Dr. Ferrier's conduct during the meeting of the Congress was a foregone conclusion. Whoever first instigated the prosecution was evidently suffering from the blinding effects of prejudice, and his excess of zeal in a foolish cause has had its usual and well-merited result. If the treatment to which Dr. Ferrier has been exposed is a fair sample, it is evident that these short-sighted and false friends of animals have determined to show towards those who make vivisectional experiments, and those who try to learn from those experiments, not even the commonest courtesy and fair play. Without the slightest intimation of their intention, the Society for the Protection of Animals from Vivisection, through Mr. Waddy, publicly accused Dr. Ferrier of breaking the law, and, not content with asking for a summons against him in a quiet manner, attempted by an *ex parte* statement to damage his reputation. By this aggressive action of the anti-vivisectionists, the question of the immense value of the experimental method as applied to living animals is once again raised. The issue is not one to be feared or avoided by the profession. In this country, at any rate, experiments on living animals have always been conducted by only a limited number of the most eminent members of the profession. Their object has at all times been clear, and the results attained have been so important and of such lasting benefit to men that we have a complete answer to give to any who, carried away by a feeling which is most praiseworthy when rightly directed, would challenge, on the ground of its uselessness, our right to "vivisect."—*Lancet*.

DISEASED MEAT AND OVERCROWDED TENEMENTS IN LONDON.

At a late meeting of the City Commission of Sewers, Dr. Sedgwick Saunders, the Medical Officer of Health, reported that during the preceding week over six tons of diseased meat had been seized at the slaughter-houses and markets. Public attention having been directed to the alleged overcrowding of houses in Windsor Street, and other streets in Bishopsgate, a night inspection had been made, and, while the result did not justify the charge of overcrowding, it was impossible to exaggerate the dirty condition of the premises, owing to the filthy habits of the inmates. In Windsor Street there were 12 houses with 103 rooms, in which 359 people dwelt; in Widegate Street, 7 houses, 48 rooms, and 88 persons; in Sandy Row, 6 houses, 49 rooms, and 124 persons; and in Catherine Wheel Alley, 3 houses, 16 rooms, and 73 persons. No persons were found sleeping in the basements; and the allegations freely made by irresponsible persons, that large numbers of persons occupied these rooms in the night alternately, had not been borne out. The structural condition of the majority of the houses would not justify any attempt to demolish them, although it must be

¹ *Boston Medical and Surgical Journal*, September, 1880, page 140.

admitted that the habits of the occupants were not conducive to health, morality, or decency. The disposal of the refuse of the city was also discussed, and it was proposed to conduct, at an expense of over £9000, experiments on a patent process for consuming it; the subject was ultimately adjourned, in order that the court might obtain counsel's opinion upon matters involved.

The *Medical Times and Gazette* thinks it is to be regretted that the magistrates generally will not combine in an effort to put down the disgusting traffic in bad and unwholesome meat which is still openly carried on in England, and that the only method to effect this would be to abolish fines and inflict imprisonment in every case.

THE POSITION OF THE EMBRYO IN THE FOWL'S EGG.

In a short article on the Position of the Embryo in the Fowl's Egg, communicated to the *New York Medical Record*, Dr. J. C. Dalton says:—

During the last summer I opened one hundred fowls' eggs, from the first to the third day of incubation. Of these, in four instances the embryo was longitudinal in position, with its head once toward the pointed end of the egg, and three times toward the round end; in twelve it approximated the position described by Foster and Balfour, namely, with its right side toward the round end and its left side toward the pointed end of the egg; while in the remaining eighty-four its right side was toward the pointed end and its left side toward the round end. But, among the last-mentioned cases there were only fifty in which its position was exactly transverse in regard to the egg. In thirty-four it was more or less oblique; the head being inclined in twenty-six cases toward the pointed end, and in eight cases toward the round end. In the twelve cases, furthermore, where the embryo lay with its two sides in the position described by Foster and Balfour, it was exactly transverse in only five, being more or less oblique in the other seven.

The position assigned to the embryo by Kölliker is therefore correct for the large majority of cases (eighty-four per cent.); except that it is not so rigidly transverse as might sometimes be inferred from the language of the books, but presents an occasional obliquity, most frequently toward the right. An increased deviation in this direction may shift the position of the embryo, in different cases, around the entire circle. But, notwithstanding this variation with respect to the exterior form of the egg, the relation of the embryo to the yolk and the embryonic spot is not necessarily altered. As the globular yolk is already fecundated at the time of its exit from the ovisac, and receives its envelopes of albumen and egg-shell afterward, the various positions of the embryo in the egg may be due to the manner in which the yolk is received into and transported through the oviduct. The egg receives its ovoid form in the oviduct, from the unequal deposit of albumen in front and rear of the advancing yolk; and the segmentation of the cicatricula (the first step in the formation of the embryo) goes on within the oviduct, and is nearly or quite complete in the new-laid egg. The position of the embryo on the surface of the yolk is determined by the mode in which segmentation takes place in the cicatricula; and this is very possibly the same in all cases.

But the yolk may vary its position in the fully formed egg, according to the way in which it entered the oviduct and there received its albuminous envelopes. Consequently, the embryo may vary from its usual position with regard to the two ends of the egg, without any change in its relation to the yolk or the cicatricula.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM DECEMBER 3, 1881, TO DECEMBER 9, 1881.

MURRAY, ROBERT, colonel and surgeon, medical director, Military Division of the Missouri. The leave of absence granted him in S. O. 100, October 5, 1881, Military Division of the Missouri, extended two months. S. O. 272, A. G. O., December 2, 1881.

SUMMERS, JOHN E., lieutenant-colonel and surgeon, medical director of the department. Granted leave of absence for twenty-five days. S. O. 123, Department of the Platte, December 1, 1881.

WRIGHT, J. P., major and surgeon. The leave of absence granted him in S. O. 229, November 8, 1881, Department of the Missouri, extended twenty days on surgeon's certificate of disability. S. O. 123, Military Division of the Missouri, December 2, 1881.

PERLEY, H. O., captain and assistant surgeon. At the expiration of his present leave of absence to report in person to the commanding general, Department of the East, for assignment to duty. S. O. 274, A. G. O., December 5, 1881.

TAYLOR, A. W., first lieutenant and assistant surgeon. Assigned to duty at Fort Supply, Indian Territory. S. O. 246, Department of the Missouri, November 29, 1881.

JOHNSON, RICHARD W., first lieutenant and assistant surgeon (recently appointed). To report by letter to the commanding general, Department of Dakota, for assignment to duty. S. O. 272, C. S., A. G. O.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—A regular meeting of the Society will be held on Monday evening, December 19th, at eight o'clock, at the hall of the Medical Library Association, 19 Boylston Place. Reader, Dr. Lawrence. Subject, Phonic Paralysis, with Rapid Respiration.

M. H. RICHARDSON, M. D., Secretary.

BOOKS AND PAMPHLETS RECEIVED.—On the Poisonous Properties of Quinine. By William O. Baldwin, M. D., of Montgomery, Ala. With Remarks by J. Marion Sims, M. D. (Reprint.)

A System of Surgery, Theoretical and Practical, in Treatises by various Authors. Edited by T. Holmes, M. A. Cantab. First American, from second English edition, thoroughly revised and much enlarged. By John H. Packard, M. D., assisted by a large Corps of the most eminent American Surgeons. In three Volumes, with many Illustrations. Vol. II. Philadelphia: Henry C. Lea's Son & Co. 1881.

The Use of Hot Water in the Local Treatment of Diseases of the Eye. By Leartus Connor, M. D. (Reprint.)

The Practice of Medicine by Women in the United States. Emily F. Pope, M. D., Emma L. Call, M. D., C. Augusta Pope, M. D. A Paper read before the American Social Science Association at Saratoga, Wednesday, September 7, 1881.

Chronic Club-Foot successfully treated without Tenotomy by continuous Extension and Stretching. By James S. Green, M. D. (Reprint.)

A New Gynecological Table. By W. A. B. Sellman, M. D. (Pamphlet)

Transactions of the Michigan State Medical Society for the Year 1881.

The Prevention of Stricture and of Prostatic Obstruction. By Reginald Harrison, F. R. C. S. London: J. and A. Churchill.

The Physician's Daily Pocket Record, comprising a Visiting List, many Useful Memoranda, Tables, etc. By S. W. Butler, M. D. Sixteenth Year. New and thoroughly revised Stereotype Edition, with Metric Poological Table, etc. Edited by D. G. Brinton, M. D. Philadelphia: Published at the Office of the Medical and Surgical Reporter. 1882.

The Nurse and Mother. A Manual for the Guidance of Monthly Nurses and Mothers. By Walter Coles, M. D. St. Louis, Mo.: J. H. Chambers & Co.

Deaths reported 2571 (no report from Chicago and New Orleans); 824 under five years of age; principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 661, consumption 359, lung diseases 320, diphtheria 239, scarlet fever 115, typhoid fever 85, small-pox 54, diarrhoeal diseases 41, malarial fever 36, whooping-cough 25, puerperal fever 16, cerebro-spinal meningitis 15, erysipelas 10, measles five, typhus fever one. From *scarlet fever*, New York 67, Brooklyn 20, Philadelphia and Pittsburgh nine each, Buffalo four, St. Louis three, Cincinnati two, Baltimore, Milwaukee, Providence, Charleston, Cambridge one each. From *small-pox*, Pittsburgh 28, Philadelphia 14, New York and Holyoke three each, Cincinnati two, Brooklyn, St. Louis, Baltimore, Buffalo one each. From *malarial fever*, New York 14, St. Louis nine, Brooklyn eight, Buffalo three, Baltimore two, District of Columbia, Milwaukee, Nashville one each. From *whooping-cough*, New York eight, Baltimore two, Brooklyn, Boston, District of Columbia, Buffalo two each, Philadelphia, St. Louis, Pittsburgh one each. From *puerperal fever*, Boston three, New York, Brooklyn, St. Louis, Buffalo two each, Charleston, Salem, Holyoke, Newton one each. From *cerebro-spinal meningitis*, New York and Philadelphia three each, Pittsburgh, Buffalo, Milwaukee two each, Providence one. From *erysipelas*, New York and Buffalo two each, Boston, St. Louis, Pittsburgh, Providence, Worcester one each. From

measles, New York three, Buffalo, Providence one each. From *typhus fever*, New York one.

In 37 cities and towns of Massachusetts, with a population of 1,610,359 (population of the State 1,783,086), the total death-rate for the week was 19.80 against 18.40 and 18.06 for the previous two weeks.

For the week ending November 12th in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 22.4. Deaths reported 3264: acute diseases of the respiratory organs (London) 433, scarlet fever 142, measles 112, fever 76, whooping-cough 73, diarrhoea 39, diphtheria 34, small-pox (London 27) 28. The death-rates ranged from 11.9 in Leicester to 39.5 in Hull; Sheffield 21; Leeds 21.7; Birmingham 21.9; London 22.3; Bristol 23.4; Manchester 24.6; Liverpool 28.5. In Edinburgh 21.9; Glasgow 23.1; Dublin 21.3.

For the week ending November 5th in the 21 chief towns of Switzerland, population 479,934, there were 16 deaths from pulmonary consumption, diarrhoeal diseases 15, acute diseases of respiratory organs 10, typhoid fever eight, diphtheria and croup four, whooping-cough three, measles one, puerperal fevers one. The death-rates were, Geneva 22.9; Zurich 20.3; Basle 13.4; Berne 23.4.

NOTE. — The other foreign reports have been delayed by rough weather and long passages. — Ed.

ADDRESS DELIVERED BEFORE THE MASSACHUSETTS MEDICO-LEGAL SOCIETY.

BY ROBERT AMORY, M. D., OF BROOKLINE, PRESIDENT OF THE SOCIETY.

GENTLEMEN of the Massachusetts Medico-Legal Society.—It is now four years since the medical examiners' law went into effect, and upon this fourth anniversary of the organization of our Society I desire your attention to a review of its operation, but first let me preface my remarks. The abuse of the old principle of a coroner's jury led, as you are well aware, to the present change in the system of legal inquiry into the cause and manner of suspicious death, and an attempt has been made by the legislature to divide this inquiry between two officers; and placed first in order of inquiry was the determination of the medical cause of the suspicious death, and, second, the juridical exposition of the responsibility for this death. Our duty as medical examiners being concerned in the successful operation of the present law, we should, from time to time, endeavor to ascertain whether the object provided for in the first-named division is constantly and properly carried out.

Can a correct explanation of the cause of death in cases of supposed violence be as well obtained under the present as under the old system of investigation? Our able associates have informed us that, theoretically, the answer to this question is affirmative, but its practical proof is better known to us than to others, and is sufficiently attested by an appeal to the annual returns of our own active members, which have been duly summarized in turn by your executive committees, and now are deposited in this medical library.¹

The statute requires that the medical examiners must be "able and discreet men, learned in the science of medicine," and "shall be liable to removal from office at any time by the governor and council for cause shown." Consequently, any one holding this commission cannot plead inability to ascertain any cause of death which is now familiar to the best pathologists; hence, if upon simple view of a dead body he has a reasonable opinion of the cause of death, whether by natural means or by violence, he may immediately take appropriate action, and if by the latter he shall then state his opinion in a communication to the trial justice; but if he cannot thus readily satisfy his own mind the law provides that the medical examiner may, after obtaining proper authority, examine the corpse post mortem. Thus it would seem as if every means were placed in the hands of the medical officer to form, so far as human skill will allow, a correct judgment of the cause of death. Yet we must not forget that our present knowledge of the causes of death is very far from complete, and that some cases will arise, and even have already arisen, as most of us who have had any practical experience in these affairs will confirm, wherein even medical science fails to elucidate the doubt. Unfortunately the community expects more knowledge from the medical practitioner, not only of the causes and cure of disease, but even of the causes of death, than we have any right to pretend to. Now, under the old law it would, at first sight, seem just to expect that a jury of medical men, under the

authorized investigation of the coroner, would more correctly arrive at a definite conclusion of the cause than would the present medical examiner by his own unassisted inspection and judgment. This is, however, a fallacy, because, in the first place, it was very difficult for the coroner to get an intelligent medical jury, and so most usually the jury was composed of some men who were educated in medical knowledge and of some who had none of this knowledge, hence the verdict was confusing and perplexing. Again, it must be admitted that medical men differ in judging similar circumstances, and hence sometimes a jury composed of medical men only would give a misleading verdict. Now, however, the medical examiner may form his judgment without interference from others. As this judgment of facts and results from inspection must be reduced to a written opinion it is susceptible of review and criticism, and hence will require care and truthfulness in its preparation. Having to form an opinion of the cause of death only, and not of its human agent, no technicalities of law come between him and his own conclusions.

Practically we must admit the wisdom of the principle of this legislation, for its workings and processes are simple, and are concerned with matters about which the medical practitioners of to-day should be thoroughly familiar. In brief, then, the medical examiner has simply to put into practical operation the faculties of observation which he employs daily, while he has nothing to do with learning upon whom the responsibility of criminal accountability may lie.

The brief synopsis I have thus given leads to the natural inference that the means offered by law for the correct explanation of the cause of death by supposed violence has proved an incalculable benefit to the community in general on account of the substitution of positive knowledge for speculative doubt. I might also cite the advantage that the present quiet and dignified method of procedure has over the now obsolete excitement caused by the coroner and the impanelled jury; the medical examiner privately examines and privately communicates the result of his examination. Moreover, the increasing amount of information obtained by the careful and close attention required throughout the State from those who investigate and report the diagnosis of the cause of death, is a benefit to medical education.

When the new law was first put in force, undoubtedly many cases were reported to the medical examiners which need not necessarily have been examined by them, for though the deaths were mysterious, the mystery was concerned only with natural causes, and not with those of violence; yet society required the medical examiner in these cases to certify as to the cause of death, and oftentimes he was unable to do this without a post-mortem investigation. Our more recent experience shows that many of the cases which were at first, owing to this cause, included in our annual returns should never have been reported to the medical examiner. In these cases the fact must not be overlooked that it was wiser to err in cases of doubt upon the side of too much rather than too little investigation.

But just here let me call the attention of this Society to a fact of which many of you are apparently ignorant. In our archives is stored a very valuable amount of material for pathological study, as related in the reports of cases which are carefully indexed and arranged for

¹ At 19 Boylston Place, Boston.

easy reference. These cases should be examined and read for the information of our various members, who will learn much that is interesting to them in their official capacity, even if no mention be made of the advantages they possess for the medical practitioner. If many of these cases were known to you, much of the questioning made at our meetings as to the methods and conduct in certain unexpected official perplexities would appear to you superfluous, and very much that is interesting to scientific research would receive the attention of members who now rarely join in discussion. If the future of this Society is to be an important link in forensic medicine, more energy and active zeal is required from the county medical examiners, before whose eyes I am sure many interesting pathological questions have been brought, and from whom much valuable information can be obtained.

No one would hesitate to pronounce, from the knowledge we have gained in the practical study of the causes of death by supposed violence, that justice under the present process of our law is greatly facilitated in the acquisition of the actual determination of the causes which led to the death of the victims of crime. The picture which has so often been brought to the view of the individual members of our Society, in which is discovered the corpse of a person who apparently has met with a violent death, either from his own hands or that of others, is peculiarly vivid. Instead of hurriedly convening a jury from a gaping and curious crowd around the scene of recent violence, the medical examiner is hastily summoned, and rapidly proceeds to take charge of the body and to remove it quietly and decently to a secluded place; during the time that his application for an autopsy is being surveyed and considered by the proper authorities, he has time to summon two competent witnesses, who when practicable should always be physicians; then with locked doors he calmly and carefully makes the autopsy, reduced to writing by the aid of a qualified clerk, and from this record he draws up a clearly defined report which is immediately forwarded both to the trial justice and to the district attorney. Here end the functions of the medical examiner. It thereupon becomes the duty of the trial justice to make inquest as to the responsibility of the violent death, if it is shown in the aforesaid report that it was caused by the agency of man. After he has held an inquest the judge, or trial justice, gives his verdict, which is the first public announcement since the medical examiner was first summoned. Can anything be simpler? There can be no conflict of opinion, because on the one hand the medical examiner pronounces the medical causes of death, and on the other hand the judicial officer determines whether this cause implicates a problematical criminal responsibility. In order to fix the individuality of the responsibility, the district attorney lays the whole matter before the grand jury, which may or may not return a bill of indictment.

I hope the Society will pardon me for speaking thus in detail of matters which are as familiar to its members as they are to its president; but it is important that we should keep these facts always in plain view. I doubt very much whether our present reformed legislation would have waited so long for the law of to-day, if the coroners of the State had met together as often as has this Society, and thus have probably brought about the same reform as now exists. When we were first commissioned, we were all aware that the success of the medical examiner's law depended upon the abil-

ity and competency of the officers commissioned to carry out its provisions, and, being unacquainted with our new duties, naturally we met together and organized this Society. Does any one of its members for a moment realize that the success of the present law is assured? Do we not all of us, and each one, know that if we cease to exist as a society the influence we now exert upon the community will be seriously weakened, and the mutual benefit derived from interchange of views will be lost to us, and that future appointments to be made by the executive might be selected which would depreciate the qualifications of our successors? Do not understand me to impugn the character of the present, or any other chief executive of our State; but we all know that the appointments of county officers, and medical examiners are county officers, have been in more than one instance relegated to the councillor of the district, and the appointment issued upon his nomination. For this, even if for no other reasons, it becomes the duty of this Society to make its influence and power felt, not by scheming for successors to office, but by establishing a name for probity, earnestness, careful scientific research, and for the collection and storing of valuable information obtained by each one of its members. Nor let the work stop here; material facts and earnest work are of no great value, unless each one of us endeavors to increase our knowledge, not by questioning and answers only, but by earnest discussion of cases coming under our personal knowledge, or of those reported at our various meetings.

I have spoken of the advantage to the community and to justice in the present law concerning medical examiners. The advantage to the medical profession is also great. An authorized autopsy in case of a sudden death by supposed violence presents a means of study in pathological science which is invaluable. I do not wish to insinuate that in the new law the facilities for post-mortem investigations are any easier than under the old coroner's law; indeed, experience shows that the facilities for unnecessary dissection are not so great, but are only allowed for the better advance of the ways of justice, and needless autopsies are checked; yet the medical officer must examine carefully and deliberately, for his own reputation, and even still further, for the better guide to his written opinion, for which he alone, unsupported by a jury, must prepare himself. The result of all this is the collection of a very valuable series of post-mortem observations in many cases of death which have been caused by natural lesions; because there are many cases of death in which violence is suspected which are proved by the autopsy not to have resulted from the hand of man. I doubt whether the autopsies held by coroners under the old law were as carefully conducted, because here the coroner had simply to charge his jury with such information as he deemed essential to their minds, which generally were not educated in medicine, and his jury gave its verdict, which was a brief summary of a preliminary examination to a charge of murder, or else simply a statement that the deceased came to his death by natural disease or by the hand of Providence.

It seems to me that the practical operation of this law has also relieved the district attorney of the weighty responsibility of deciding whether the coroner and his jury had sufficiently examined the medical aspect of the case, and in a way to assist him in his preparation for the court; while, again, he cannot help being

satisfied with the verdicts rendered by the magistrate. Our associates, the district attorneys, can inform us, if they wish, whether or not, under the present law, the statement is not warranted that the facts of the crime and the cause of death are more truly set forth at present than in the old coroners' time. From what little has passed under my own observation I feel confident that these officers go into the investigation of their cases now with more satisfaction than was their wont six years ago. They feel pretty sure whether the victim came to his death naturally or by the hands of another. I cannot, however, forbear to mention, in this connection, that but few of these officers have lent much active help to our Society, and I regret that the professional demands upon their time and attention have apparently robbed us of their counsel at our meetings. From the little we have heard from them, I feel confident that we are being continually deprived of very valuable assistance which they could give to us if they would attend our meetings.

One great boon to the State, resulting from the medical examiner's law, will be duly presented to you in the report of your executive committee: This is in relation to the costs to the counties of inquests under the coroners' law, and under the new statutes. As this was the main argument which led to the abrogation of the old statute, and to the institution of the new law, I think you will be much interested in the material facts which we have been able to obtain from the various county commissioners. I will not forestall your interest in this portion of our review, but will simply say that the figures of costs, for three years, bear out the fact that the new law has been more economical than the old statute.

Thus we can claim for the advantages of our new legislation, after four years of its experience: (1.) That the investigation of the cause of death after supposed violence is unattended with the disagreeable and harassing circumstances of partial publicity which were necessary under the old coroner's system. (2.) A more certain and definite knowledge of the cause of death. (3.) An inquest under a magistrate who presents his verdict without the inconvenience of a jury. (4.) A written and detailed account, from both medical and judicial examiners, which forms a more convenient record for use by the district attorney in presenting the case before the grand jury. (5.) A financial saving to the treasury of the counties. (6.) An opportunity for study of pathological science.

I cannot refrain, moreover, from expressing a summary of the work which your Society can accomplish. (1.) A mutual exchange of opinions which will serve to increase the educational knowledge of the medical examiners. (2.) The elevation of the office of a medical examiner so that competent persons will be desirous of appointment. (3.) The collection of a valuable record of autopsies and statistics for reference by the general practitioners of medicine as well as by the medical examiners. (4.) The establishment of a discussion in forensic medicine among our profession, the lack of which has suffered this subject to be neglected in our State. (5.) The establishment of concerted action under the influence of which future appointments to office will insure competent men. (6.) A censorship under whose censure incompetent officers shall be removed from their office.

I need not say that the maintenance of this Society and its objects requires much sacrifice of time and de-

votion to its interests on the part of its members, and it should be the duty of the officers of this Society to influence you individually and collectively to exertion and active zeal to promote these objects.

I owe you, gentlemen, an apology for myself in resigning my commission, and thus being deprived of lending an active support to this Society, but you must be aware that my absence from the State for nearly a quarter of each year would render me liable to the criticism that I was derelict in duty, and hence I felt obliged to vacate my commission, and at the same time to resign an active membership in your body; and, moreover, I deprive myself of the honor of being your president.

I cannot retire from this chair without expressing my thanks for the honor you have conferred upon me, and for the courtesy you have always extended to me, and hope that my successor in office will enjoy as much as I have done the work of conducting your meetings, as well as of maintaining the organization which my predecessor and myself first conceived soon after our commissions were given us. I shall always give you what support I am able, and shall always look with pride upon the written work which may be stored in your archives.

A CASE OF UNITED CHILDREN OR DOUBLE MONSTROSITY.¹

BY JOSEPH STEDMAN, M. D.

Mrs. A. B., age thirty-five years, mother of three children; labors normal; first only three hours; ceased to menstruate March 28, 1880; commenced to be very uncomfortable, and suffered a good deal in May following with pain in the right side, apparently at first of the abdominal muscles, for which soothing lotions and a bandage was applied. About September 20th so much pain and distress was developed in the region of the liver and right side of the abdomen that it was impossible for her to be comfortable in any position, sitting, moving about, or reclining. Thinking that continued rest in bed for a series of days would be beneficial I directed her not to rise from the recumbent position for a week, for any purpose whatever. Although she strongly objected to this, it was persevered in and after three days she experienced considerable relief. At this time I made careful examination by auscultation and otherwise, thinking it might be a case of twins, but could not satisfy myself on this point. After ten days' rest she was allowed to sit up a portion of the day, and during the remainder of her pregnancy was much more comfortable although she could not move around without great pain and discomfort, and spent the most of her time in a Wilson reclining chair. Labor pains commenced November 28th and were regular and of good character. I saw her at nine p. m. and found the os dilating well, a vertex presentation, first position.

The pains continuing and dilatation being well accomplished, and not much progress being made, I ruptured the membranes and the head descended into the pelvic cavity. After the liquor-amnii was evacuated, there being a large amount of it, I made an external examination and found another head above the pubes which could not be felt before. I now supposed I had twins to deal with, and as the pains were vigorous

¹ Read before the Boston Obstetrical Society.

and no further progress seemed to be made, after a half hour's delay I applied the forceps and delivered the head. The body not following I made an examination and found another head in the pelvic canal. Still supposing I had twins I made some slight effort to push the second head up so to allow the body of the first child to come down; not succeeding readily I made more careful examination, and although I could not determine any union of the children I felt quite sure I had a monster to deal with, and decided to deliver the other head by the aid of the forceps. This I did after some careful manipulation without any injury to the mother. The delivery of the body was soon accomplished after the heads were delivered, and I found it to be a case of double monstrosity, still-born.

I have the pleasure of exhibiting the specimen to the Society, together with a written report of the examination very carefully made by Dr. W. F. Whitney.

The patient made a good recovery and her strength and general tone is as good as after the birth of her other children.

The monstrosity is represented by the union from clavicle to umbilicus of two otherwise well-formed male fetuses, face to face. Condition known as thoracopagus.¹

The weight, without the placenta, was 4970 mgm. One fetus, which will be called A, was 47 cm. in length, the other, called B, was 48 cm. Each head measured 33½ cm. in circumference, and was well covered with long hair. A single testicle could be felt in each scrotum. The nails did not reach to the ends of the toes.

The placenta was single, and weighed 680 gm. The cord was short, and carried two arteries and two veins.

The umbilical cord entered the abdomen at one edge of an oblong slit, eight cm. in its longest diameter, which had been covered at one time by an extremely thin membrane, remnants of which were still adherent to the edges. From this opening coils of small intestine protruded.

The right hypogastric artery from each fetus furnished an artery to the cord, while the left could be traced but a short distance above the bladder, where it ended as an impervious string. The umbilical veins remained closely united but distinct, and entered the liver together in a deep fissure.

An incision was made along the line of union on one side, and the integuments dissected back, when it was found that each sternum had failed to unite along its own middle line, but that the lateral halves had joined those of the opposite fetus, and in this way was formed a common thoracic cavity. The union of the integuments as far as the umbilicus formed a common abdominal cavity to that point. From there the abdominal cavities were distinct but communicating.

The internal organs which presented any marked peculiarities were the hearts, the liver, and the intestinal tract below the diaphragm.

The hearts lay in a common pericardial sac. The auricular portion presented no external line of separation, while the ventricles, which were slightly raised upward and tilted to the right, so that the base of A was close to the apex of B, were distinct but slightly adherent to each other by a narrow, firm band of connective tissue.

Upon opening, the auricular portion was found to consist of a single cavity, in which were partial folds and incomplete septa, marking, first, the line of separation between the two hearts, and then between the right and left auricles of each heart.

The line of separation between the heart of A and B was simply a slight folding or constriction of the wall of the sac at its central portion.

The portion of the sac which was thus marked as belonging to A was partitioned off by a muscular septum reaching through two thirds of the height of the sac. This septum was perforated by a large circular opening (Eustachian valve) allowing still further communication between the two portions. Into the portion which would correspond to the right auricle there opened the inferior and superior vena cava and the pulmonary veins, and from it there was a passage into the right ventricle closed by the valve. From the right ventricle, which was quite small, the pulmonary artery was given off as usual, and from the left branch of this the ductus Botelli, which was rather long and slightly twisted, passed to the aorta.

The portion of the sac which would correspond to the left auricle communicated freely with the right auricle of B, and had a passage into its own left ventricle, from which the aorta was given off in the normal manner.

The portion of the sac which represented the auricular parts of the heart of fetus B was also subdivided by a septum, which was much lower than in the case of A, and was imperforate. The portion, then, which would correspond to the right auricle communicated on the one side with the left auricle of fetus A, and on the others with its own left auricle, but there was no opening into the right ventricle, nor did it receive any vessels. The part corresponding to the left auricle received the superior and inferior vena cava and the pulmonary veins, and opened in the usual manner into the left ventricle, from which the aorta was given off. Upon cutting into the right side of the ventricular part of the heart a cavity was found connecting with the pulmonary artery. This latter was filled with a friable, reddish clot to the bifurcation, the ductus Botelli being given off from the left pulmonary artery close to that point. The supply of blood to the lungs must, then, have been furnished from the aorta through the ductus Botelli.

There was a double set of all the abdominal viscera except the liver, which was a large, deeply and irregularly fissured mass, in which no line of separation could be distinctly traced. The only indication of a gall-bladder was a dark discoloration in a fissure on the under surface of the organ, opposite where the pancreas joined the intestine. In fetus A the vena cava inferior was completely surrounded by a lobe of the liver for a short distance. In fetus B the relation was normal. In neither case was there any trace of the ductus venosus.

The stomachs in both were rather small but normal in position, and passed normally into the duodena. These extended for a distance of from six to nine cm. when they terminated with a flaring mouth, as if the intestine had been cut across obliquely. Lying in close proximity to these were two sacs of about the size of a small orange, in each of which was an oblong slit three to five cm. in extent opening freely into the abdominal cavity. These sacs contained a considerable quantity of discolored mucus. On the same side with

¹ Foster. *Medical and Surgical Monographs*.

the slits, and at a short distance from them, there passed off the continuation of the small intestines, which in the rest of their course were normal, as were the large intestines.

The remaining organs were normal in position, number, and form.

In brief, then, the monstrosity is one of thoracopagus, having a cord carrying two arteries and two veins, the ductus venosus entirely wanting, the auricular portions of the heart united into a common cavity, with no right auriculo-ventricular opening in the case of fetus B, and in consequence the lungs receiving their blood from the aorta through the ductus Botelli. The livers fused into one mass, with an absence of gall bladders, the duodena opening freely into the abdominal cavity, and the small intestines recommencing again with two large ampullae, also opening into the abdominal cavity.

RECENT PROGRESS IN OTOTOLOGY.

BY J. ORSE GREEN, M. D.

A NEW ROUTE FOR THE EXTENSION OF MASTOID INFLAMMATION TO THE NEIGHBORING TISSUES, AND THE NECESSARY TREATMENT IN THESE CASES.¹

It has fallen to the fortune of Bezold to explain satisfactorily, and apparently to prove experimentally, the pathology of some of the complications of mastoid inflammation, which have undoubtedly been seen by all who have had much to do with ear disease. Reference is made to those cases where inflammation of the mastoid is followed by extensive inflammation of the tissues of the neck and by deep-seated suppuration, often ending fatally from simple exhaustion or from involvement of some of the important vessels in the neighborhood. Beginning as a purulent inflammation of the tympanum, with or without perforation, the mastoid is soon involved, tender on pressure, and showing a slight œdema, which, however, does not go on to fluctuation. A decided inflammatory infiltration of the upper posterior osseous meatus is always present. After weeks, or even months, suddenly a new complication sets in, namely, swelling and tenderness just below the point of the mastoid at the insertion of the muscles. This swelling rapidly extends along the muscles, then forwards to the fossa retro-maxillaris and downwards along the large vessels of the neck, the swelling becoming as "hard as a board." There may be now a rupture of pus into the meatus at the junction of the cartilaginous and osseous meatus.

The swelling may cease at these limits or may gradually extend backwards and downwards over the whole side of the neck, and finally show indistinct fluctuation at the anterior edge of the trapezius muscle. The swelling may extend upwards to the superior curved line of the occiput and far down the muscles of the neck. If rupture has occurred into the meatus, or if the mastoid cells have already been opened by operation, an upward pressure on any part of the swelling evacuates pus from these openings. Incisions in the swollen tissues only reach pus when they are made very deep. As the swelling passes backwards severe pain is complained of in the occiput.

It is deep incisions and thorough drainage are used recovery may slowly result. In many cases, however, death results from exhaustion, from involvement of the

vertebræ, from œdema of the glottis, or from pus burrowing into the thorax. One case is given where there was paresis of both upper extremities, stiff neck, difficulty of swallowing, and death from œdema of the lungs.

The explanation of this series of symptoms is considered by Bezold to be an extension of the mastoid inflammation into the digastric groove either through an inflammatory perforation or through a natural porosity or dehiscence of the bone at that point, favored by the thinness of the bone and the large number of small vessels perforating it at that spot. The pus once penetrating the groove it is prevented from showing itself externally by the digastric muscle, the broad tendon of the splenius capitis, and trachelo-mastoid, and by the sterno-cleido mastoid; it also is now in close contact with the occipital artery. The anterior edges of the splenius and trachelo-mastoid are connected by connective tissue with the fascia parotidea-masseterica, and backwards the tendons of the sterno-mastoid and splenius spread out like a fan and connect with the tendon of the trapezius. The pus is thus confined between the deep muscles and fasciæ of the neck and burrows along them and along the sheaths of the vessels, especially along the occipital artery, a branch of the external carotid.

Bezold tested experimentally the course of fluids injected into these parts by boring through the mastoid into the digastric groove and then forcibly injecting colored gelatine, at first a swelling of the insertion of the muscles of the mastoid was produced, then a swelling in front and behind, which gradually extended to the fossa retro-maxillaris, and then to the chin; finally the injected mass passed backwards, forming an extended swelling as far as the median line and downwards one third of the neck. Dissection then showed that the gelatine had passed along the belly of the digastric muscle, under the parotid, and along the sheath of the occipital artery to the carotid; the artificial infiltration was confined to the upper part of the neck. Backwards the gelatine passed along the occipital artery, and was found in three successive strata between the deep muscles, namely, between trapezius and splenius, splenius and complexus magnus, and the largest quantity of all was between the complexus and the short deeper muscles of the neck, running down even to the second dorsal vertebra.

For the treatment of such cases Bezold recommends perforating the digastric groove through the mastoid cells, entering the cells at the lower part of the mastoid process and extending the opening into the incisura mastoidea. One case is given of the disease treated in this way which was healed in fourteen days.

DISPLACEMENT OF THE AURICLE FOR REMOVAL OF FOREIGN BODIES FROM THE MEATUS.²

After narrating a case of his own where a pebble was deeply impacted in the meatus and could not be removed by any of the common methods, although tried faithfully, and was finally removed by the above operation, Moldenhauer discusses the three different methods which have been proposed for opening the meatus after displacement of the auricle. Entering through the anterior and lower wall he condemns on account of the necessary wounding of blood vessels, injury of the parotid gland, and of branches of the facial, the close neighborhood of the articulation of the lower jaw, and

¹ *Tr. B. Soc. Med. Wochenschrift*, No. 28, 1881.

² Moldenhauer, *Archiv für Ohrenheilkunde*, vol. xviii., p. 59.

from the fact that the anterior lower wall is usually very convex towards the meatus, this curvature thus constituting a natural obstruction to the use of instruments and to the removal of the body.

The objection to opening the upper wall is that it is necessary to cut through such a depth of soft tissue that both light and space are small for getting at the body. All of these objections are avoided by opening the posterior wall, which gives a short, straight, and large passage, directly to the body, and the only possible objection to this method is the probability of cutting the posterior auricular artery, in itself of no consequence whatever.

In a note to Moldenhauer's paper, Schwartze says that he has performed the operation of displacement of the auricle, not only for removal of foreign bodies, but also for the extraction of large sequestra, and for the removal of exostoses in the deeper osseous meatus. In every case, he says, since he began to use Listerism he has obtained healing by primary intention.

ARROSION OF THE INTERNAL CAROTID ARTERY, THE RESULT OF CARIES OF THE PETROUS BONE.¹

In a case of caries of the petrous bone produced by chronic suppuration of the tympanum, the patient had a sudden and enormous hæmorrhage from the internal carotid artery, which was fatal in a few minutes. The few similar cases which have been reported being scattered in medical journals and scarcely referred to, even in text-books on the ear, Hessler has compiled and analyzed as follows:—

He divides the cases into three classes, the first containing thirteen cases in which autopsy confirmed the fact that the hæmorrhage came from the carotid; the second containing six cases where the confirmation by autopsy was wanting, but the diagnosis was in all probability correct; the third three cases where, although there was no hæmorrhage, an autopsy showed that the osseous carotid canal was destroyed and the artery itself was surrounded by pus.

An analysis of the first class, the only one which can be regarded as scientifically complete, shows that the age of the patients varied between nine and fifty years; two were about ten, two about twenty-two, and five between forty and fifty years of age. It occurred eight times in men and three times in women. In eight of twelve cases the rupture occurred eight times in the left and four times in the right carotid. The duration of the suppuration of the ear, the cause of the carious destruction, is given as nine, eight, seven, eleven, and nine years; in two cases as several months, and in one case, that of a syphilitic person, as only short.

The hæmorrhage generally occurred very suddenly, without warning and without any reason, such as violent exertion; it varied in degree, in some cases was slight, in others severe. When slight it could be checked by a tampon in the meatus, when severe it required long continued digital compression in the neck. In most cases it kept recurring daily. In three of the twenty-two cases there was one single enormous hæmorrhage which was fatal in a few minutes.

Ligature of the carotid was performed in three cases, namely, those of Baizzan, Broca, and Pilz. In the first the left common carotid was ligated but the bleeding recurred at the end of twenty-four hours and was fatal, by three repetitions, in the course of the next three days. In the second the right internal carotid

was tied and the bleeding checked entirely, the patient dying two months after from tuberculosis of the lungs. In the third case the right common carotid was ligated by Billroth, and there was no bleeding for nine days; it then began again from the ear, mouth, and nose, and although checked by compression kept recurring till, on the fourteenth day, the left common carotid was tied; three days after this a severe hæmorrhage from the ear, mouth, and nose ended fatally.

Hessler, in his discussion of the treatment of these hæmorrhages, and from a consideration of the anatomy, and especially of the anastomoses of the vessels, concludes that in severe arterial hæmorrhages from the ear the common carotid should be ligated, although even if this is done, a collateral circulation through the *circulus arteriosus Willisii* may renew the bleeding.

REPORT ON INSPECTION OF FOOD AND DRUGS.

BY B. F. DAVENPORT, M. D.

ON account of the exaggerated assertions of some that our food and drink are well nigh universally adulterated it is very gratifying to learn, through the investigations of the Boards of Health, both the National and those of the several States, what are the real facts of the case. They have been found not to be nearly as bad as reported. Most of the adulterations and substitutions in the staple articles of food, with the exception of milk, are but commercial frauds against the consumers' pocket and not on the public health, and they can mostly be easily avoided by such as are willing to pay for a finished manufactured product a fair advance upon the necessary cost of good crude materials to the manufacturers themselves. In the case of drugs, however, the results are more serious if we do not get the necessary therapeutic action of the true, good drug. Health may truly suffer in an emergency as severely from the fact of want of proper activity in a drug as from over or even wrong action. The mere fact of a manufactured food or pharmaceutical preparation being offered at a low or even lower price than the claimed ingredients are known to cost in their crude condition, if of fair quality, ought to be enough to excite, even in the most trusting minds, at the least, a suspicion of all not being quite right, while anything short of a fair advance should do so in all others. Suspicion once excited the real facts are usually easily ascertainable. The investigations have vastly multiplied since the reports of Dr. Hassall, of the Analytical Sanitary Commission, were first published in the *London Lancet* of 1851. The progress of sanitary legislation is in no respect more marked than in the enactment of the laws to prevent the adulteration of food or drugs recently passed by the States of New York and New Jersey. These are based upon the report prepared by experts appointed by the National Board of Trade to award prizes in a competition for the draft of the best law to prevent food adulteration, and are largely framed upon the experience gained under the English Sale of Food and Drugs Act of 1875. The text of the New York law is given on page 117 of this volume of the JOURNAL.

The most important recent American publications have been Supplement No. 6 to the National Board of Health Bulletin for July 17, 1880, containing the re-

¹ Hessler, *Archiv für Ohrenheilkunde*, vol. xviii., p. 1.

port of Prof. C. Lewis Diehl on Deteriorations, Adulterations, and Substitutions of Drugs, and R. C. Kedzie's (President of the Michigan State Board of Health) report on the Adulteration and Deterioration of Food, the Supplement No. 11, of January 1, 1881, containing the report of an Investigation to Determine the Prevalence of Adulteration in Food Supplies, by Dr. Charles Smart, U. S. A., and the Supplement to the *Sanitary Engineer* of December 1, 1880, containing the report of the Committee appointed by the National Board of Trade for the purpose of awarding prizes for the best act, accompanied by an essay, designed to prevent injurious adulteration and to regulate the sale of food and drugs.

The first really useful adulteration act passed the English Parliament in 1872, while Canada passed its similar act in 1874. The present German act is since 1879. The Swedish is the most comprehensive, and provides against the coloring of wall-papers and other decorations with arsenic, the use of aniline or other injurious colors in fabrics for clothing, and the sale of pigments of any injurious character. Its provisions are exceedingly stringent. By a local law of Frankfurt-on-the-Main, a milk inspector perambulates the market and dips a pointed stiletto into each can of milk exposed for sale. If from the way in which the milks runs off from the polished surface of the steel he suspects it to be adulterated, he simply lets the stiletto fall back into the can, thereby punching out a hole for the milk to flow off.

For such articles of food as naturally vary in their constituents the Society of English Public Analysts have fixed the following limits: Milk shall contain not less than nine per cent. by weight of milk solids not fat, and not less than 2.5 per cent. of butter fat. Skim milk not less than nine per cent. of milk solids not fat. Butter not less than eighty per cent. of butter fat. Tea, dried at 100° C., not more than eight per cent. of mineral matter, of which at least three per cent. shall be soluble in water. The tea as sold to yield at least thirty per cent. of extract. Cocoa at least twenty per cent. of cocoa fat. Vinegar at least three per cent. of acetic acid.

Dr. Charles Smart's report shows that American wheat flour is not mixed with alum, but that the bakers use it. Our sugars are clean, but we have glucose admixtures. Our coffees are good from the custom of grinding it before the purchaser at the time of sale, while that sold in ready-made packages shows a tendency to debasement. Our ground spices, such as pepper, cloves, and mustard, are as bad as the English at the time official attention was directed to them. But fortunately with such exceptions as the alum in bread and baking materials, the gypsum which often replaces cream of tartar in household baking, the debasement of milk by dilution, and the poisonous pigments used for coloring confectionery, the adulterations in foods are not seriously injurious to the public health.

If it is assumed that the consumption of fresh milk averages one hundred and twenty quarts per capita per annum, this would amount to forty-two million quarts for a city of as many inhabitants as Boston. The value of this at six cents per quart amounts to \$2,520,000. Were this watered to only the common amount of twenty per cent. it represents a sum of \$504,000 paid a year for this needless adulteration. Bearing in mind that milk has been found adulterated with equal parts of water, it appears what large sums

might be unwittingly paid out in this manner for a single article of food in a single large city.

Professor Diehl finds the American drug market, although offering too many instances of deteriorations, impurities, and contamination, adulteration, or sophistication and substitution, to be unqualifiedly fair. That is to say, that those who really desire to obtain articles of standard quality have very little difficulty in doing so, and as a general rule can be suited by respectable dealers throughout the country. On the other hand, ignorant persons or those regulating their purchases by the prices rather than by the quality, and being consequently indifferent as to the character of the dealer, are very likely to meet with low grade and adulterated goods, or at best are frequently supplied with goods of an indifferent character. As an instance of this last may be noted the fact, published in a recent article by Dr. R. V. Mattison, that four fifths of the so-called commercial red cinchona bark of the market is bark which has been rejected by the quinine manufacturers as being nearly or quite devoid of crystallizable alkalis, and beyond what tonic qualities may be expected from the cincho-tannic acid present, is quite devoid of any virtue as a medicine. This explains why the older physicians do not seem now to obtain as much benefit from their old well-tried remedy, Huxham's tincture of bark, as they did in earlier years of practice. This bark, sold by the bark importers of New York at a usual price of five to ten cents per pound, goes to the general retail apothecary at prices varying from twenty-five cents to \$2.25, according to the extent of his ignorance or indifference upon the subject of "barks." The prevalence of sophistication in wines and spirits is too well known to need much comment. There have been soaps in the market that contained seventy-five per cent. water that externally could not be distinguished from that containing only twelve per cent. A late analysis of a solution of magnesia citrate sold by a New York manufacturer has shown it to be nothing else than sodium tartrate.

Hospital Practice and Clinical Memoranda.

BOSTON CITY HOSPITAL.

SURGICAL CASES OF DR. GAY.

REPORTED BY R. A. KINGMAN.

CARIES OF THE ANKLE; AMPUTATION.

CASE I. E. G., female, seventeen years old, was admitted in May for caries of the ankle. Has had trouble with the ankle since she was two years old, two small pieces of bone having come away at different times. Dr. Ingalls removed the os calcis and scraped the astragalus on June 8th, before the Massachusetts Medical Society. The foot did not heal after this operation, but abscesses formed at various points, until the whole ankle was riddled with sinuses. September 19th the leg was amputated by Dr. Gay, without the spray, but with plentiful application of carbolic solution, and with other antiseptic precautions. The leg was then dressed with the regular Lister dressing, which extended to the middle of the thigh. Catgut ligatures and silk sutures were used, and a drainage tube inserted.

The dressing was changed daily until the 25th, when

the drainage tube was removed. Next dressing on the 28th, when a few of the stitches were removed.

October 30. All sutures removed. The wound has healed by first intention, except in the track of the drainage tube, and the discharge is very slight. Three days later the dressing was changed to cosmoline, and on November 11th the patient was walking about on crutches, the wound entirely healed, little or no sensitiveness remaining in the stump. The only complaint during convalescence has been of pain in the toes, which has entirely disappeared.

DISEASE OF THE KNEE-JOINT; AMPUTATION.

CASE II. P. J., thirty-five years of age, has been laid up since last December with disease of the knee-joint and femur. He was in the hospital at that time, and was advised to submit to amputation above the knee, that joint being disorganized in consequence of pulpy degeneration of the cartilages. He, however, refused operation, and left the hospital. August 16th he reëntered, and consented to any operation that might be thought necessary. His general condition was very poor; he had frequent and profuse diarrhoea, lack of appetite, slept poorly, and had a large bed-sore over the sacrum. The thigh was riddled with sinuses, which discharged copiously. He was immediately placed upon treatment preparatory to operation, and rapidly gained in strength and improved in spirits.

August 29th Dr. Gay amputated at a point a little above the middle of the thigh, choosing for his operation the transfixion method. This was done in order to save time, and thereby lessen the amount of shock. The tissues of which the flaps were composed were so infiltrated and hardened that it was with great difficulty that ligatures could be applied and made to hold. The method of conducting the operation and of dressing the wound were precisely the same as in the last case. After the operation the patient was placed in one of the small tents which have for several years formed an important addition to the wards of the hospital during the summer, upon a fracture bed, in order that the bed-sore might be more easily dressed.

The subsequent treatment consisted of free stimulation and nutrition, and frequent dressing with Lister gauze, at first daily and then less often. September 25th the dressing was changed to liquor sodæ chlorinatæ.

October 8th. Sat up. Stump all healed but a small sinus which traversed one of the flaps at the time of operation.

November 1st. Discharged, well.

MALIGNANT TUMOR OF THE HUMERUS; REMOVAL; SUBSEQUENT AMPUTATION.

CASE III. B. T., ten years old, born and brought up in Nova Scotia, was admitted September 17th, with a bony tumor on her left arm. It was situated on the outer aspect of the arm just below the head of the bone, of irregular outline, size of the child's fist, painless, did not impair motion. The mother said it had been there since the child was two years of age, but had lately begun to grow rapidly. She desired it removed merely because it was a disfigurement. The tumor was removed the same morning by Dr. Gay, who easily detached it with a chisel.

It was found to be composed of an irregular nodular mass of cancellous bony tissue infiltrated by a soft and partially disintegrated material, the whole of which

was covered with a layer of pearly-white cartilaginous tissue. The shaft of the humerus, at the point of removal of the tumor, consisted of the same loose cancellous tissue, which was easily broken down under the finger.

In view of the evident malignant nature of the tumor, it was apparent that the only way to eradicate the disease, and save the child's life, was to amputate at the shoulder-joint, but this the mother would not consent to.

The wound was packed with sponges, and bandaged firmly to control the hæmorrhage, and opiates were freely given by mouth and subcutaneously. This dressing was changed in two days to Lister gauze, and this was renewed daily. The wound discharged very freely an offensive serous fluid containing little pus. The temperature went up, and for six days remained between 101° and 103° F. She could eat little, and vomited almost constantly.

September 24th. Patient feels better to-day. Temperature 99.2° F. The wound is being distended by a mass of fungous granulations. Offensive serous discharge continues.

October 2d. After a consultation of the surgical staff to-day the consent of the parents was obtained to amputate the arm at the shoulder-joint, and this operation was accordingly done by Dr. Gay. In order to escape the tumor an outer skin flap was made, the humerus disarticulated, and then by transfixion an inner flesh flap was obtained. The vessels were secured with catgut, the wound was douched with strong carbolic solution, and the flaps were brought together over a drainage tube with silk sutures. Dressed with Lister gauze, to be changed daily.

After this operation the same difficulty was experienced as after the previous one, namely, vomiting and anorexia. Opiates had to be given for pain referred to the fingers of the amputated arm. Stimulants and nutriment were given by rectum for nearly a week.

October 5th. A slight hæmorrhage occurred from the wound, which stopped spontaneously. Evening temperature 104.5° F.

October 6th. Drainage tube removed. From this date patient began to improve, and steadily gained up to the time of her discharge. After October 8th the dressing was changed and the wound irrigated twice daily.

October 10th. Stitches all removed, the wound having healed, all but two small sinuses.

October 24th. Discharged, well.

RAILROAD INJURY; AMPUTATION AT THE SHOULDER-JOINT.

CASE IV. John D., fifty-seven years old, born in Ireland, was run over by a railway train September 28th, sustaining a crush of the left upper arm. The humerus from the elbow to the neck was completely splintered, merely the head of the bone being left intact. The surrounding soft parts were nearly severed from the body, and all the tissues as far as the scapula were severely lacerated and contused. The clavicle was also broken. The patient was etherized, and the arm was amputated at the shoulder-joint, the operation consisting merely in trimming off the lacerated tissues and removing the head of the humerus. The edges of the skin were approximated as nearly as possible over a drainage tube by means of silk sutures, and the wound dressed with Lister gauze. Brandy was given before and after the operation both by mouth and by rectum. During the first twenty-four hours after oper-

ation twenty-four ounces of brandy were given, the amount being then reduced to eight ounces *per diem*. Patient reacted well. The dressing was changed every morning, the discharge being free, but not excessive.

October 1st. Patient a little delirious during last night, but otherwise doing well. Champagne, one pint, in addition to brandy. Moved to one of the small tents.

October 5th. Has been very restless and noisy every night until last night, when he slept under the influence of bromide and chloral. Part of the sutures removed yesterday, when two small sloughs came away. Quinia, five grains, three times a day. Champagne omitted.

From this date patient continued to improve without interruption. The wound contracted to a small sinus, which was still discharging slightly at the time of his discharge, November 16th.

AMPUTATION AT THE ANKLE WITH HEEL FLAP.

CASE V. Harry C., three years of age, was run over by a railway train October 12th, and was brought immediately to the hospital. His right foot was found to be crushed, the ankle-joint being opened, and most of the tarsal bones being more or less injured. The amount of shock not being very great he was etherized at once, and the foot removed at the ankle-joint. The malleoli were cut off with a scalpel, ossification having not yet taken place. The os calcis was dissected out, and a posterior flap made of the skin of the heel. Dressed with Lister gauze daily.

Patient has had very little pain, and the amount of discharge has been small. Additional support has been afforded the flap by means of straps of rubber plaster. At the end of a month the wound has healed with the exception of a small sinus at the side and a small granulating patch in front. Not yet discharged.

SARCOMA OF THE FOOT; AMPUTATION.

CASE VI. Fanny M. entered the house October 25th with a tumor of the heel, which she first noticed eight years ago. At that time it was about the size of a filbert, and was not very painful. A year ago last March she had the tumor removed in this hospital, it being described as a tumor, size of a small orange, painful on pressure, firm, and not lobulated. It soon began to grow again, and at the expiration of a year she underwent another operation at the Massachusetts General Hospital. After the latter operation the tumor grew rapidly, and now involves the whole of the heel and part of the plantar surface of the foot. Large nodules of exuberant granulations are pushing out in all directions, and the intervening integument is marked by numerous veins, which ramify over the surface of the tumor. Her general appearance is that of extreme anemia, although she is not at all emaciated. The glands in the groin are not enlarged.

October 28th the leg was amputated in the same way and with the same antiseptic precautions as in Case I. The blood which was lost during the operation was extremely dark in appearance, and coagulated only after long exposure to the air. She rallied well after the effects of the ether had passed away, but complained of pain in region of heart. Gave morph. sulph. subcutaneously, one eighth grain, ordered brandy, two drachms, every hour. In the evening her stomach began to reject the brandy, and it was omitted. She was then given nothing but iced champagne by

mouth, brandy and milk being given by rectum every three hours.

The next day she began to reject the enemata, and several times she vomited the champagne.

October 30th another subcutaneous injection of morph. sulph., one eighth grain, was given on account of the same pain in cardiac region. The enemata were continued, but had to be kept in by manual pressure on the anus. At four P. M. she was given an intravenous injection of warm cow's milk, three ounces, Aveling's apparatus being used. This produced no appreciable effect, for she continued to sink until 5.55 P. M. when she died.

The tumor was accidentally destroyed so that no examination could be made, but the probable diagnosis was sarcoma.

A FATAL CASE OF POISONING BY GELSEMIUM.

BY WM. WATKINS SEYMOUR, M. D. (HARV.), TROY, N. Y.

I REPORT the following fatal case of gelsemium poisoning in the hope that it may bring out other cases which have occurred, and may draw the attention of experimentalists to the necessity of determining its proper antidotes and their indications. Since the termination of the case I have searched for everything I could find relating to the drug, and find only a single case of poisoning mentioned (a fatal one reported by Dr. Wormley). The case I report is the third which has come to my knowledge. One occurred in the consulting practice of Dr. Wm. L. Cooper, of Troy, then of Michigan, where, to a lying-in woman, her attendant gave by mistake for ergot a teaspoonful of the fluid extract of gelsemium. Ten minutes later Dr. Cooper saw the patient, who was extremely prostrated, almost pulseless, and the respiration failing. He administered mustard and ginger several times, and stimulants, and the patient recovered. A few years since a young lady, of this city, died in Saratoga from a teaspoonful of the fluid extract of gelsemium, administered by mistake for geranium.

My patient was a very muscular man, twenty-eight years of age, about five feet ten inches in height, and one hundred and eighty pounds weight. I was called by a relative to see him December 6th, at three P. M. The relative said he had been drinking more or less for several days, but on that day instead of drinking he had taken at intervals some drug, which the patient told him was gelsemium, to quiet his nerves. His condition finally became such that the relative called me, fearing that what he had taken might prove fatal. I found the patient with clothes on lying upon bed, dozing, and looking very much as if he had been upon a spree; he was easily roused, and talked intelligently; the face was pale; eyes flushed, pupils moderately dilated, and reacting to light, slight ptosis of both upper lids; pulse strong and full, about 100; no odor of alcohol about the breath; skin seemed normal to touch. At first the patient would not tell me what he had taken, but finally said he had taken three drachms of the tincture of gelsemium in twenty-drop doses, every four hours, had repeatedly taken such doses to quiet his nerves after drinking, and could stand any amount, saying he knew all about the drug, as he had studied medicine. Finally he said he had taken two ounces of the tincture. I talked with him some twenty-five minutes, and as the last dose had been taken suffi-

ciently long for its absorption before I saw him, and as there was nothing alarming in his condition, I advised detention in his room, watching, and at any sign of failure of heart or respiration, to give stimulants freely, and call me.

At four p. m. I was called by messenger, who said the patient had eluded his watcher a few minutes before, and had procured at a drug-store, a thousand feet distant, one half ounce of fluid extract of gelsemium, which he drank. I hastened with stomach-pump to his quarters, and could not find him. With his uncle I searched the hotel, top and bottom, as the watcher said he had not passed him, but in vain. After a twenty-five minutes' search we found him at a shop a couple of hundred yards distant. He was sitting in a chair, but had little control over his movements, the limbs were relaxed, face pale; he recognized us, and spoke, but said he would not take an emetic. I had him held, and while his head was thrown back I introduced a funnel into one nostril, and poured a solution containing twenty grains of sulphate of zinc into the throat. The patient was obliged to swallow, and copious emesis followed. He then voluntarily took plenty of warm water, and a second dose of ten grains of sulphate of zinc, and vomited it also. However, he became speedily unconscious; pulse 130, respiration 40, and entirely thoracic; pupils moderately dilated, but reacting to light. I gave two drachms of brandy subcutaneously, and an ounce by rectum. Then, as the condition did not materially improve, the lips being blue, and skin livid and cold, I faradized the diaphragm and intercostal muscles, applying the electrodes eighteen or twenty times a minute. The respiration dropped to 20, and became full and natural, the pulse became stronger, and the color of skin and lips became rosy. Such was his condition at seven p. m. that I went to get my dinner, and was absent fifteen minutes. When I returned he was breathing long and full; pulse about 130; color slightly blue. I then repeated the injection of brandy, one ounce, and the faradization of the respiratory muscles. With this treatment the breathing became better, but the capillary circulation was poor, there being a tendency to lividity and cold extremities and skin. Applied heat, gave one fortieth grain of atropia subcutaneously to strengthen heart and improve capillary circulation. Pulse and color improved, but did not last long. I tried inhalations of nitrite of amyl without effect. I then repeated brandy, one ounce by rectum, faradic current to diaphragm and spine, and gave carbonate of ammonia subcutaneously. At 9.15 there was a tendency to lividity, skin was cool, and the pulse 135, still I regarded his condition as such that I told his uncle he might go off for fifteen or twenty minutes to get something to eat (he not having eaten since morning), but proposed first that we should move the patient on the blanket on which he lay nearer to the fire, as the room was becoming cold. This was done by grasping the four corners of the blanket, and gently lifting him. Immediately after his face became pale, his lips blue, the respiration and heart stopped, and the patient, at 9.25 p. m., was dead. No autopsy was had.

In view of the lack of experimental authority I did not dare give large doses of atropia or digitalis, for I feared that to prove effective they would have to be given in doses so large as, under ordinary circumstances, of themselves to prove fatal. When I first used the faradic current (Kidder's one-cell battery) the reac-

tion was prompt and very satisfactory, but it seemed, later, to lose its power.

For a drug which is so much used there seems to be very little known about its toxic doses and antidotes. My father, Prof. Wm. P. Seymour, of Troy, who has prescribed it a great deal, particularly in gonorrhoeal inflammation, regards the doses usually given in the books as likely to give rise to all the disagreeable physiological though not toxic effects. Two minims of the fluid extract three times a day frequently affected sight so that a book-keeper could not write, and four minims three times a day frequently produced weakness of legs and staggering.

I am reminded of the toxic effects of another drug in popular use for criminal purposes, namely, tansy. This year I have seen two cases where the drug produced convulsions and delirium, and in one coma and dislocation of the jaw from convulsive action, and I am informed that in many cases it has produced dangerous and, in some cases, fatal inflammation of the bowels without any oxytoxic effect, and find that the books give little or no information regarding its antidotes or mode of destroying life.

DEATH FROM SUNSTROKE THIRTY-FOUR HOURS AFTER EXPOSURE. AIR OR GAS FOUND IN THE HEART.

AUGUST 7th, at 2.40 A. M., I first saw Marshall T. This was Sunday. On Friday preceding, an intensely hot day, he was exposed to the sun's rays for the greater part of the day. Returning home he ate a light supper, and retired, having made no especial complaint of feeling unwell. Saturday morning he rose, ate a light breakfast, walked to a neighbor's, who noticed nothing unusual, returned, and immediately went to bed, where he remained until death took place. About six p. m. Saturday he complained of "feeling sick," and between eight and nine became wholly unconscious. They had given him about fifteen grains chloride of ammonium, which was the only medicine he had taken.

The most persistent questioning elicited only these meagre facts. He appeared to have made so little complaint that he was left almost wholly alone for nearly twenty-four hours.

No history of nausea, and no vomitus found.

When I saw him, six hours after he became unconscious, he was lying on his back, motionless, skin burning hot and dry, temperature 109.1° F., pulse 132 and feeble, respirations 24; no stertor; pupils about normal size, irresponsive to light, conjunctivæ slightly congested; respiration shallow, moaning with nearly every expired breath; tracheal râles. Patient had had a large involuntary defecation. I drew off eight ounces of urine of a strong, peculiar odor, in which, afterward, a trace of albumen and a few granular casts were found. The man was evidently dying, and lived only fifteen minutes after I saw him.

The autopsy was made twelve hours after death, under the direction of Dr. Geo. B. Twitchell.

Rigor mortis slight. Peripheral vessels in the head very much congested. Considerable congestion of the pia mater. More serum than normal in the left lateral ventricle. The whole brain substance was softer than normal, but nothing more pathological was seen. Extensive and firm pleuritic adhesion around both lungs.

The lungs themselves were so congested as to yield an almost solid resistance on palpation, and incision showed the congestion to be uniform nearly throughout. The aortic valve of the heart was slightly insufficient, kidneys granular, the left more so than the right. On opening the left ventricle of the heart *in situ*, quite a large number of air bubbles rushed out. None were seen in the right ventricle. The left ventricle contained considerable blood in a fluid state, the right but little. No coagula found. The blood was strongly acid in reaction.

The congested state of the membranes in the head, the intense congestion of the lungs, the general fluid condition and strongly acid reaction of the blood, all confirmed the diagnosis made from the ante-mortem symptoms, that is, sunstroke, notwithstanding the time elapsing between exposure and death, but how to account for a large number of air bubbles intimately mixed with the blood in the left heart cavity was a question evolving explanatory theories which would perhaps hardly bear publication. The only wound found on the body was a small ulcer of the leg. The air or gas had no odor.

Dr. R. H. Fitz, to whom I referred the question, kindly answered as follows: "Decomposition is apt to occur very early in cases of death from sunstroke, and the ante-mortem temperature of your patient was so high that an acceleration of ordinary cadaveric changes was likely."

I remember two cases in Boston during the early summer, where death resulted from an air embolus entering the circulation through the uterine sinuses, as shown by autopsies. GLO. H. BRIDGMAN, M. D.

KELNE, N. H., October 8, 1881.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

MEDICAL SECTION.

H. C. HAVEN, SECRETARY PRO TEM.

OCTOBER 22, 1881. Meeting called to order at eight p. m., Dr. H. I. BOWDITCH in the chair.

Dr. W. F. WHITELY presented a communication entitled Four Cases of Disease of the Pancreas, of which the following is a brief abstract.

CANCER OF THE PANCREAS.

This case occurred in the practice of Dr. I. F. Giddons, of Lynn, who furnished the following clinical notes. The patient was a widow, fifty-five years of age, naturally of a weakly constitution and thin in flesh. On October 11, 1880, he first saw the patient, who was suffering from severe pain in the abdomen, diarrhoea (the discharges frequent, liquid, and bloody), and vomiting. The diarrhoea lasted two weeks and was followed by persistent constipation. The pain in the epigastrium was severe and continuous, accompanied by throbbing. The food was often regurgitated several hours after ingestion.

Nothing was detected by physical examination until January 15, 1881, when a hard, pulsating tumor, without thrill or bruit, was felt in the left hypochondrium below the lower edge of the ribs.

The patient died February 23, 1881. The autopsy,

made on the 26th, revealed a firm mass lying just below the stomach and adherent to the adjacent parts. The liver was studded with white nodules from the size of a pea to that of a nutmeg. The further examination showed that the mass consisted of a body the size and shape of the pancreas, but much firmer, and was surrounded by hard lobulated bodies, evidently enlarged glands. The pancreatic duct was found and a fine probe could be passed its entire length. Under the microscope the normal pancreatic structure was seen to be replaced by moderately large, rather cubical, epithelial cells, arranged in alveoli, which were close together in some parts while in others they were widely separated by dense connective tissue. The structure of the enlarged glands as well as of the nodules in the liver was similar to the more cellular portion of the diseased pancreas. The case was evidently one of a gland-celled cancer, more nearly approaching scirrhus in parts.

HEMORRHAGE INTO THE PANCREAS; THREE CASES.

The three following cases are closely associated as illustrating the different ways in which hæmorrhage may affect the pancreas.

The first case has already been reported by Dr. F. W. Draper,¹ who has kindly allowed the specimens to be exhibited which were prepared at that time. In this, which represents the most acute form, fresh blood is found extravasated everywhere into the interstitial tissue throughout the whole organ. Death followed so quickly that there was no time for secondary changes to have taken place.

The next case is one where the hæmorrhage was more localized, and secondary changes more marked. The case occurred in the practice of Dr. Charles D. Homans, who has kindly given the following history: "The patient was a robust man, past middle life, who had been seldom ill enough to stay at home. He had had at times attacks of 'colic,' the result, apparently, of indigestion, and usually easily relieved. In 1880 he had an attack of what was called 'jaundice,' lasting from the middle of February until the first of May. He was very yellow, had no appetite, great disinclination to move about, and some epigastric pain. During the greater part of the time he was able to come into the city and attend to business, but would, from time to time, be confined to the house during a day or two. He seemed to have recovered perfectly from this attack and never appeared better than just before his fatal illness.

"On February 24, 1881, he came to town at his usual hour in the morning complaining of some pain at the pit of his stomach. He kept about his occupation during the day with more or less pain, but was finally obliged to go home several hours earlier than usual. He was seen the next morning, when he had, apparently, symptoms of peritonitis attended with great prostration. He gradually sank and died about fifty-four hours after the first complaint of pain. At the autopsy, made by Dr. E. G. Cutler, the peritoneum was found to be generally reddened; in the other organs, except the pancreas, there were no changes worthy of note."

The pancreas, which I had the opportunity of examining, presented the following appearances: It measured twenty cms. in extreme length. Upon section the color was found to be in general of a dirty red. The interlobular tissue was of an opaque white,

¹ Vide JOURNAL, vol. ciii., p. 615.

as if a crayon of nitrate of silver had been lightly passed over it. Near the centre of the organ and extending completely through it, from above downwards, was a wedge-shaped nodule, brownish-black in color, mottled with the same opaque white. The nodule measured 4.5 cms. at one side and tapered to 1.5 cms. on the other, and was slightly softer than the surrounding tissue, and also projected above the surface. There were several spots similar in appearance, measuring from one to two cms., situated in the head of the pancreas, and one near the opposite extremity. The microscopic examination showed that the color of the nodules was due to the presence of diffused blood-coloring matter in the tissue, while there were to be seen scattered clumps of amorphous blood-coloring matter in the interlobular spaces, the white discoloration being caused by the presence of vast numbers of short staff or spindle shaped crystals in the fat tissue. The outline of the pancreatic cells was lost, and their nuclei were indistinct and failed to take coloring matter, but osmic acid, aside from turning the whole section of a uniform dark brown, failed to reveal the presence of a fatty degeneration.

The third case was one in which an extensive purulent infiltration was found about the pancreas with sloughing of the organ and thrombosis of the splenic vein, the whole probably resulting from hemorrhage. The case occurred in the practice of Dr. J. C. Harris, of Arlington, who has furnished the following account: "Mrs. M., past middle life, was of her usual health until September, 1879, from that time until December 20th complained only of an uncomfortable feeling at the pit of her stomach and general debility. This did not prevent her from attending to her customary household and social duties. At this latter date she was suddenly attacked by severe pain in the epigastrium, accompanied by vomiting. These symptoms continued till her death, which occurred December 25th, and were only partially relieved by large doses of morphia and ether. The vomitus was very abundant and consisted of a dark-green viscid fluid: the stools frequent and similar in appearance to the fluid vomited. The temperature was about normal during the five days of her illness. She slept little until the last day and then only at long intervals."

At the autopsy, which was made thirty six hours after death, there was noted marked lividity of dependent portions of the body, with the formation of large blebs filled with a bloody serous fluid. The head was not opened. The peritoneum was moderately injected. The heart was distended with a considerable amount of dark liquid blood. Spleen small, capsule slightly wrinkled; on section it was found to be extremely soft, follicles not to be distinguished. The kidneys and liver were in an advanced stage of decomposition, bubbles of gas issuing from both organs upon pressure. The pancreas was large and firmly adherent to the adjacent parts, which were infiltrated with a discolored purulent fluid. A section showed the entire substance of the gland transformed into a dark, slaty-colored, stinking mass from the end of the tail to within about three cms. of the point of attachment to the intestine, where was a distinct line marking the boundary between this and the more healthy remaining portion. The splenic vein, where it was in contact with the pancreas, was filled with a dark, soft clot, slightly adherent to the walls of the vessel.

These three cases represent the changes which may

be found in the pancreas after hemorrhage into that organ.

In the first case, where death occurred within fifty-four minutes, there was found simply fresh blood in the interstitial tissue. The whole amount could not have exceeded forty to fifty grammes, and it is difficult to accept this as a sufficient mechanical cause of death. It is much easier to conceive of the hemorrhage as the accompaniment of some lesion, as yet overlooked, of the central nervous system, and standing in the same relation to it that the subserous ecchymoses and pulmonary extravasations do to injuries of the head, or else consider with Zenker that it is the cause of profound changes in the nervous centres through reflex action of the sympathetic.

In the second case, where the patient lived about fifty-four hours, the seat of the hemorrhage appeared to be localized at several points in the organ. There was also evidence of peritonitis found in this case, which may be regarded as a sufficient cause for death, but in what relation it stood to the hemorrhage there is no means of determining.

In the last case, in which death occurred at the end of five days, the purulent infiltration and necrosis which appear to have followed a previous hemorrhage (as shown by the slaty discoloration) are an obvious and sufficient cause for death.

DR. C. D. HOMANS said that at the time of the autopsy of the patient spoken of as having been under his care, he had believed death to be due to peritonitis, and the appearances seemed to him to justify that belief; moreover, the clinical history of the case seemed to indicate the existence of peritonitis as the principal cause of the most marked symptoms, namely, the swelling and tenderness of the abdomen.

DR. PRINCE suggested that in these cases death might be due to shock.

DR. WHITNEY said that Zenker explained death by reflex influence on the heart from pressure on the semilunar ganglion or pneumogastric nerve. He thought the word shock did not express any recognizable condition, and that it was quite as easy to suppose a primary disease, possibly of the brain, which manifested itself by the hemorrhage into the pancreas; this was of course the merest supposition, but it had occurred to him as a possible explanation. We have a condition somewhat analogous in head injuries with the resulting subpleural extravasations.

DR. PRINCE reported the case of a man where there had seemed to be a hemorrhage into the pancreas. The clinical history, in brief, was as follows: When first seen, he was in extreme collapse, pulseless and very restless, cold sweats, abdomen tender and swollen. He was sent to City Hospital; seemed to rally after intravenous injection of milk, but died later of secondary peritonitis.

Autopsy by DR. GANNETT, who stated that there was found only a small part of the head of the pancreas lying in a pool of pus; there was evidence of recent hemorrhage, probably from pancreas; there was also peritonitis, gluing together the coils of intestine.

DR. BOWDITCH asked if the pathological process seemed to have been of recent origin.

DR. GANNETT replied that there was at the time no means of ascertaining.

In reply to a question as to the previous condition of the patient, DR. PRINCE stated that for some weeks

before the patient had been in jail, and apparently perfectly well; about one week before the attack described, however, he complained of severe abdominal pain immediately after turning a somersault.

DR. GANNETT spoke of two cases of cancer of the pancreas; the first primary, where the head was a mass of scirrhus disease, the rest of the duct being dilated; the ductus choledochus and hepatic duct were involved; in the second case the middle portion of the pancreas was affected, and it was impossible to decide if it or the omentum was the original site.

DR. KINNEAR asked if there was any record of traumatic injury of the pancreas causing death by shock.

DR. WHITNEY knew of none such.

DR. KINNEAR said that in cases of so-called shock the skin was pallid, the pulse feeble, and all the symptoms pointed to internal congestion. It therefore seemed to him fair to assume that the base of the brain would become suddenly congested, and give rise to the condition known as that of shock.

DR. T. B. CURTIS said that the discussion in regard to shock and peritonitis had reminded him of what Professor Guillot calls peritonism. Gosselin also describes patients dying of strangulated hernia without any strangulation, there being a failure of nervous force. Baille Legendre describes three kinds of shock: (1.) Inhibition of respiratory nerves. (2.) Inhibition of cardiac nerves. (3.) Inhibition of nerves governing nutrition.

DR. BLODGETT asked, in relation to the first case reported, what was the path of infection from the pancreas to the retro-peritoneal glands; was it a direct propagation, or the result of irritation, or, again, entirely independent?

DR. WHITNEY replied that the microscope showed cancer of the glands mentioned, and they, being in immediate connection with the pancreas, presumably became affected through contiguity.

DR. BLODGETT asked the time intervening between death and autopsy in the case reported by Dr. Gannett, who replied that he could not state exactly at present, but that no other organs showed any signs of digestion. Dr. Blodgett thought that the loss of substance of the pancreas might have taken place suddenly, although the presence of pus showed that the process had existed a certain length of time.

DR. BOWDITCH insisted on the great importance of knowing the previous history in forming a judgment upon such a case; we were often led into error by a too summary record. He also recalled that formerly, in quite an extended pathological experience, he had met with but one case of hemorrhage into the pancreas, and even then Dr. J. B. S. Jackson insisted that he had not got the pancreas.

DR. J. B. AYER read a paper on

THE TREATMENT OF DIPHTHERIA.¹

DR. T. B. CURTIS said that, as a result of his experience while interne with Roget, he had grown very skeptical in regard to treatment. He agreed with Jacob in not annoying the patient, and in relying on food rather than medicine.

In regard to tracheotomy, an early operation and careful nursing give the best results; the operation should be done as soon as there is a paroxysm of suffocative dyspnea.

In regard to the identity of croup and diphtheria, French writers now generally accept the view that the membranous disease is one and the same, sometimes local, sometimes septic. Dr. West, formerly regarded as the great opponent in England of their identity, now declares his conversion to the opposite view.

DR. BLODGETT mentioned a case of post-diphtheritic paralysis, which in spite of the best of care had grown steadily worse and was apparently incurable and would soon eventuate in death, inasmuch as the paralysis is gradually ascending. The reflex function had not been disturbed, even below, where voluntary motion is abolished.

DR. KINNEAR mentioned pilocarpin, and cited a case where the drug seemed to exercise a favorable influence.

DR. LYMAN spoke of the value of Dovers' powder and of stimulation; he thought it a blood poisoning, and that there was no specific treatment.

DR. J. AYER thought the question as to the affection being systemic or local was of little moment. He relied mostly on food, and gave Dovers' powder to induce sleep.

DR. LYMAN believed in the existence of a separate membranous croup, and recalled the first cases of diphtheria reported in Boston by himself in 1851.

DR. S. L. ABBOT reported a case of Rheumatic Chorea.²

Adjourned to December 3.

—The *Lancet* gives a very interesting account of the misfortunes of Dr. Adolph Rasch, of Finsbury, one of the physicians to the German Hospital, Dalston, who has been in the enjoyment of a large obstetric practice in the East End of London. The doctor accidentally poisoned his finger while examining a child suffering from pyæmia, some seven months ago. Shortly afterwards inflammation of the lymphatic vessels of the right hand and arm set in, accompanied by high fever, the temperature running up to 106° F., and the doctor's life being placed in the greatest danger. Although the immediate danger was averted, yet a long train of painful symptoms, indicative of blood-poisoning, followed, which must have gradually worn out a sufferer endowed with less vital energy and fortitude than Dr. Rasch. An abscess formed in the prostate, which eventually broke into the urethra and the rectum; there was embolism of the left central artery of the retina; and finally inflammation of the left knee-joint set in, which resulted in a large abscess, involving the lower half of the thigh. For a considerable time this showed no tendency to heal, and it was therefore decided to amputate the thigh. This operation was performed by Dr. Lichtenberg, in the presence of Sir James Paget and others, on October 18th. Dr. Rasch's case adds another to the long catalogue of medical men whose health has been sacrificed in the pursuit of their professional duties, who have borne their sufferings with exemplary courage, and been ready as soon as sufficiently recovered to again confront the same dangers of practice which had nearly proved fatal to them.

Recent Literature.

Eczema and its Management: a Practical Treatise based on the Study of Two Thousand Five Hundred Cases of the Disease. By L. DUNCAN BULKLEY, A. M., M. D. etc. New York: G. P. Putnam's Sons. 1881.

Monographs, to be of value, should emanate from recognized specialists of large experience and of undoubted ability. Dr. Bulkley, late vice-president of the American Dermatological Association, and editor of the Archives of Dermatology, is one of the most industrious and prolific dermatological writers of America. The treatment of eczema demands "the highest and best qualities of medical art and science" from one who must be an "accomplished physician," and an "able surgeon." These words of Sir Erasmus Wilson show the need of such a treatise as Dr. Bulkley has written, while its merits speak for themselves and are such as would have been expected from its author. It is a work to guide the general practitioner to the recognition and management of eczema; to which end practical difficulties have been met and minute directions given. It is compiled largely from separate essays written at intervals, but worked over and put into proper shape for study and reference. It shows the inherited bias of the writer in favor of the conservative, if not antiquated, views of the English school of dermatology of the last generation, but is none the less valuable, in these days of violent reactions, upon that account. Nor has he escaped the cacoëthes classificationem faciendi, proof of its existence bobbing up metastatically here, where, on general principles, it should be least expected, namely, in a special treatise. The advisability might also be questioned of giving a longer lease of life to the vast assortment of miscellaneous terms applied at different periods of the world's history to the various forms of eczema.

The chapter upon diagnosis and prognosis gives very fully and ably the differential diagnoses between eczema and other diseases of the skin, each separate disease being considered by itself in accordance with the plan employed by Dühring in his Diseases of the Skin. The dissimilarity of prurigo, the disease, from pruritus, a symptom, is recognized. The writer also says, what all must concur in, that "there is little or no tendency in eczema to a spontaneous cure; its natural course is to persist indefinitely, and even to defy treatment in many cases." "The eruption cannot be driven from one locality to another." "A striking-in of the eruption is unknown to scientific or practical medicine." "No harm comes from curing a long standing eczema." "An eruption caused by the internal administration of mercury is exceedingly rare, if it ever occurs, and never takes a form resembling eczema." "Tobacco if used at all in excess has a most harmful effect in eczema." "There is not, and never can be, any specific for eczema, nor simple remedy, nor course nor plan of treatment effective in every case, nor yet in the same case under every circumstance." "Arsenic in many cases is useless, and in many others does actual harm." "Iodide of potassium is seldom of value, and often very harmful in eczema." "Prurigo is an exceedingly rare disease in the United States, not over two or three undoubted cases having been thus far observed and recorded by those occupied with this branch." "In a majority of

cases the solid rubber bandage is unexcelled for the management of eczema, and also of eczematous and varicose ulcers of the lower extremities." Such remarks as are here quoted, though not of startling originality, are very greatly needed, the medical profession, as a body, needing rather to digest the truths it has, than to acquire more, and the authority of the writer will have great weight in spreading at large these and other truths long known to the special few. The book abounds in them and we have quoted a few merely as examples. Attention is also called to the fact that itching is a symptom, which often yields only as the disease yields and is made worse by remedies, such as morphine or opium, especially directed towards the pruritus alone. So also to the fact that early acute eczemas require soothing, old chronic ones, stimulating, treatment, diametrically the reverse of each other; and too stimulating treatment of the early stages of an acute attack often ingrain what, if let alone, would have recovered of itself. The harmful effects of soap improperly applied are mentioned; the great injury done by "cure-alls"; the stimulating and drying action of glycerine; the dangers from sponges, greases, and poultices; the connection of eczema of the anus and genitals with pruritus itself, depending upon glycosuria, and the necessity for an examination of the urine; the bad results from the use of ale, beer, or spirits in an eczema which is at all general, etc.

Perhaps the best chapter of all is the one upon the "diet and hygiene of eczema." No item which can conduce to the physical welfare of the patient is beneath the notice of the medical man who would successfully treat eczema. Diet and hygiene represent a large share of the elements of human existence, and are often, or rather always, more potent for health or ill health than what are commonly known as medicines; and what is true of the general economy is still vitally true in regard to one of the most important emunctories of the body, namely, the skin." Under "therapeutics of eczema" is given a large number of such formulæ as Dr. Bulkley has found of value in practice, and an alphabetical index concludes a volume which cannot fail to prove interesting as well as instructive to the medical reader. Especially is this true of the chapter upon *Ætiology*, a most valuable one. Whether, finally, eczema is constitutional or local depends rather upon the comprehension and use of words than upon real disagreements as to pathological conditions, and the question need not be here considered. Bostonians must also admit that their attempt to make even otherwise good writers recognize the distinction between *shall* and *will* is becoming every day, apparently, more and more hopeless. But, as a writer of to-day, Dr. Bulkley might at least have used the Metric System.

E. W.

The Practice of Medicine and Surgery Applied to the Diseases and Accidents Incident to Women. By W. H. BYFORD, A. M., M. D., etc. Philadelphia: 1881.

Professor Byford's work, in its former edition, is well and favorably known to the profession throughout the country; but this issue of the book has been so thoroughly revised, and the treatment of new subjects, and the changed methods of treatment which are required by the advance in gynecic science, have been so carefully attended to, that we come to its consideration as to a new work. The author frankly states

that he has expressed opinions and counseled practice which differ from the teachings of the last edition.

Professor Byford has conscientiously gone over the functional and organic diseases of the female organs of generation. It is a satisfaction to observe the discussion of certain topics which are often neglected by writers, notably of the sympathetic symptoms of organs apparently disconnected with the uterus, for which he will receive the thanks of the younger members of the profession.

Another topic, very widely treated, is that of constipation in its relation to uterine diseases. His first and strong point is the *demand* which should be made on nature, at definite and fixed times daily, without which no system of diet or drugging can be of avail.

All the other topics which should have a place in a work of this kind have been fully and properly treated. The disorders of menstruation, displacements, cancer, and ovariectomy have received due consideration.

We cannot fail to note the evenness and clearness of writing which mark the book, and, moreover, the evident intent to meet the wants of the every-day practitioner. There is, at the same time, a certain authority, running through its pages which shows the master's hand. It is no compilation, but the ripe experience of an actual worker in the profession. With a careful consideration of, and well expressed opinions on all new topics and methods, there is a proper sense of conservatism which gives confidence.

No truer sentence is contained in the book than this: "There must be a right and a wrong side to every disputed question; extremists are wrong."

The Prescriber's Memoranda. Published by Wm. Wood & Co., New York, 1881. The name of author is not given.

This little anonymous work gives quite a summary of therapeutical information derived from recent literature, and would serve as a pleasant handbook of reference, but, like all the condensed and abbreviated literary productions, it will be more useful to the experienced than to the inexperienced practitioner, because many of the recommended formulae are suited to a limited class of the cases for which it would seem to be a specific remedy. This book is rather an illustration of an ephemeral method of practice, and would hardly rank as a classical therapeutical memoir.

A Treatise on Bright's Disease and Diabetes. With especial Reference to Pathology and Therapeutics. By JAMES TYSON, M. D. With Illustrations including a Section on Retinitis in Bright's Disease, by WILLIAM F. NORRIS, M. D. Philadelphia: Lindsay and Blakiston. 1881.

The positions which Dr. Tyson occupies as professor of pathology in the University of Pennsylvania and physician to the Philadelphia Hospital, and his long devotion to the study of the subjects of which he writes, undoubtedly justify his cultivating a field which has already been pretty thoroughly worked over, and we do not think that those who consult his book will regret that he should have seen fit to add another book on renal disease to those of Roberts and Dickenson.

The book is a crown octavo of three hundred and ten pages, with a good index printed in good type on excellent paper. The illustrations, which are clear, accurate, and numerous, are drawn from various sources, and among them are some original ones on the histology of the kidney from the pencil of Dr. George C. Piersol. A short though full chapter on retinitis in Bright's disease by Dr. W. F. Norris adds to the value of the book.

Practical Anatomy. A Manual of Dissections. By CHRISTOPHER HEATH, F. R. C. S. Fifth Edition. With 24 Colored Plates and 269 Engravings on Wood. Philadelphia: Presley Blakiston. 1881.

So well-known a work as this one does not call for a minute review. Its popularity seems well established, and is, we think, likely to be increased by this edition. There are twenty-four reduced copies from Macleise's Atlas, with the arteries and veins colored, which will commend themselves to students. The wood-cuts are of unequal merit. Some are fresh and others are shabby from wear. It seems to us a mistake to introduce minute anatomy into a work of this description. What there is is not enough to take the place of a treatise on histology, and it adds to the bulk and expense, but not to the value of a practical guide in the dissecting room.

The Anatomist. Being a complete Description of the Human Body, intended for the use of Students preparing for Examination at the Royal College of Surgeons and other Medical Bodies. Second Edition. By G. M. H. HULLES, formerly Lecturer on Anatomy and Physiology at the Westminster Hospital School of Medicine, etc. New York: G. P. Putnam's Sons. 1881.

This is a very good compendium of anatomy. It is small and compact, but appears to contain all that can be expected in a work of this kind. It has one hundred and twenty-two illustrations, most of which, indeed, are very familiar, but others are not. The arteries are very nicely represented in red in semi-diagrammatic figures, and the nerves by white lines on a black ground. The arrangement of the book is decidedly peculiar. It is that neither of descriptive nor topographical anatomy. First come the muscles and the viscera of the different regions, then the fasciæ, then the vascular and nervous systems, then the bones, ligaments, and joints, and last of all the organs of sense. We are always glad to welcome anything like originality in methods of presenting anatomy, but this arrangement is beyond our comprehension, and the author does not offer us the slightest explanation.

— We have just received Walsh's Physician's Handy Ledger for 1881. "Handy" is the word which fitly describes its character. On a single page may be kept the record of an entire family, no matter what the nature of the cases, for one year. In addition, on the same page are debit and credit columns. We cannot conceive of a more ingenious plan of saving time and keeping a clear record. Its companion, the Physician's Call-Book and Tablet, is equally concise and convenient in its arrangement.

Medical and Surgical Journal.

THURSDAY, DECEMBER 22, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by
HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number; \$5 00
a year, including postage.

All communications for the Editors, and all books for review, should be ad-
ressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the under-
signed, to whom remittances by mail should be sent by money order, draft,
or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

EXPERT FEES IN COURTS OF JUSTICE.

A CASE of interest to the medical profession was tried in the Superior Court at Boston last week before Judge Aldrich. Dr. Thomas Dwight, of Boston, brought an action on a promissory note made by Byron A. Osgood and his wife, who defended the suit on the ground that there was no legal consideration for their promise to pay. Messrs. Russell Gray and Henry W. Swift appeared for the plaintiff and Mr. Rodney Lund for the defendants. It was proved at the trial that Mrs. Osgood met with an accident and was severely injured in consequence of a defect in a street in Lynn, and was attended by Dr. Dwight. She afterwards brought a suit against the city, and recovered heavy damages, after a long contest involving no less than four trials. At three of these Dr. Dwight was called as a witness, and was examined not only on his knowledge of the facts in the case, but also as an expert on the anatomy of the part injured, the probable results of the injury, and the prospects of the patient's recovery, and was consulted on these matters by the plaintiff's counsel before the trial. He was paid only the ordinary witness-fees, and, objecting to give his professional opinion as an expert without being paid as such, Mrs. Osgood and her husband gave him the note now sued on. The defense set up on their behalf was that a medical man is bound to testify to anything he may happen to know relevant to a case in court, whether it is a matter of fact in the particular case or of general professional knowledge or opinion; and that he cannot lawfully require for giving his opinion any greater fees than an ordinary witness is entitled to; and that, therefore, a promise to pay such extra fees is a promise to pay for doing a thing which the law requires to be done without payment, and cannot be legally enforced. The court, however, disallowed this defense, and ruled that a physician is not bound to give his professional opinion for nothing in court any more than elsewhere; that he may require to be paid for testifying as an expert; and that the giving of such evidence, or a promise to give it, is a good consideration for a promise to pay by the party at whose request it is given. Under these rulings the jury found a verdict for Dr. Dwight for the full extent of his claim.

This decision, not being made by the highest court of the State (which has never passed on the question), does not conclusively settle the law; but it affords a precedent which will probably be followed, and is

doubtless in conformity with the general opinion of lawyers in Massachusetts. In other States of the Union, so far as the question has come up, there is a conflict of authority.

TIMIDITY IN THE USE OF THE NITRITE OF AMYL.

A NEW YORK medical journal recently remarked: "General Burnside died of angina pectoris, and was not properly treated for it." What the remedy should have been the journal does not state, but the remark quoted suggests our subject, one which has frequently been forced upon us by the too general timidity in the use of the nitrite of amyl, the remedy *par excellence* for angina pectoris. Danger is supposed to attend its use simply because of its sudden, often somewhat startling effects, but, with one exception, we have never heard of a case in which it caused any harm. The exception was a young lady, who, inhaling the drug during the menstrual period, experienced some distress of a transitory nature. Between her catamenia it was administered to her without discomfort.

It were simply inhuman to allow a patient to endure the agonizing pain and the "sense of impending death" which render angina pectoris so dire, when we can offer a form of relief, in the majority of cases, nearly instantaneous. Yet a case has just come to our knowledge in which, though it was requested by the patient himself (he having previously experienced its benefit), the remedy was withheld through the timidity of the attending physician. In consequence the patient suffered the distress which for several days is apt to follow an attack of this painful disorder, unless it be checked at the outset.

Why physicians fear to use the nitrite of amyl is somewhat mysterious. There are no authenticated cases in which it has done harm. Indeed, in a selected case, when the physician has fairly assured himself of the dose required, he may safely leave it in the hands of the patient, of course with proper instructions.

It may alarm the patient if he have not been prepared for its almost electric effects. We have seen such cases. It does frequently create a headache, but if the patient have been prepared for the rush of hot blood to the skin and head and for the rapid increase in the cardiac pulsations, no mental disturbance will occur. As for the headache, which arises only semi-occasionally, it is of no consequence in view of the relief we are giving the patient.

But angina pectoris is not the only complaint in which the nitrite of amyl is a valuable aid. In the chill stage of malaria, the symptoms being extreme, we have checked the chill in forty seconds, the drug relaxing the spasm of the cutaneous vessels, and admitting warmth to the surface of the body. The febrile stage was correspondingly shortened. In the chill which often attends dysmenorrhœa we have heard it pronounced a "perfect blessing." In asthma, not always in old subjects, in whom it is apt to fail, but in cases under fifty years of age, it will clear up

riales, which can be heard twelve inches from the chest, within five minutes, and often they do not return." It will arrest spasm of the diaphragm. In all these cases, especially in angina pectoris, we have found it not only invaluable, but harmless. It is the remedy of all remedies for chloroform syncope. In partial drowning, indeed in any case of cardiac failure, it is the whip of whips for the flagging heart. In the convulsions of strychnia poisoning, in tetanus, in the early stages of epilepsy, in short, in spasm of any nature, this drug is capable of accomplishing great good. If physicians would but use it in appropriate cases they would soon see that it can be easily controlled, and, moreover, that it can be used with impunity. It is necessary only to watch the pulse and the face, and so soon as the former reaches 130, or when the nasal flush appears, stop the inhalation. It sometimes happens that the nasal flush does not at once show itself. In such an event the pulse is a reliable guide. When used with even ordinary care the drug never causes insensibility. As to the dose, two drops would be the quantity for an adult as a beginning. If this dose should prove ineffectual it should be increased boldly, especially as the specimen used may have lost strength. In another recent case of angina pectoris this drug was pronounced a delusion because it failed to relieve the patient, when the truth was that the specimen was stale. The drug may flush the face and yet not relieve the pain. This is an indication of its weakness. A fresh, strong specimen would flush the face and relieve the pain as well. It is impossible to keep the drug on hand and expect it to do its legitimate work unless it be sealed with the greatest care. It would be better to procure a new specimen for each case. Again, the remedy fails because the quantity inhaled is insufficient. Each patient is his own law in regard to the dose necessary to relieve his particular case. A drachm has frequently been administered without harmful effects. But it should be borne in mind that some individuals are more easily affected than others by equal doses. At the outset, therefore, the dose should be small, and increased until the desired result has been reached.

A convenient form of administration is a pledget of cotton-wool, upon which the liquid may be dropped. It may then be held between the patient's teeth until the characteristic effects appear.

The pioneers in the use of nitrite of amyl, Lauder Brunton, Telford Jones, Richardson, Anstie, Sydney Ranger, and others recommend it in positive terms, and Dr. Balfour in a late article¹ says: "Foremost in all our modern appliances for the relief of this dreadful breast-pang (angina pectoris) we must place the nitrite of amyl; it is perfectly safe, and may be entrusted to the patient with the certainty that he will not injure himself by its use." This is the course we have followed for some years, and in no instance has there ever been cause to regret it. Indeed, there are cases which can be managed in no other way.

As an example we may mention a gentleman who for many years had suffered several *daily* attacks of an-

gina pectoris. In this case we advised that the patient should procure a small tin box (salve or percussion-cap box), fill it with cotton-wool, moisten the wool with the drug before leaving the house, and if pain came on that he should inhale from the box. He was directed to follow the same course in case of attacks at home. A short trial of this plan proved its efficacy. In any case of frequently recurring attacks of this disease, the remedy should be kept in the house of the patient, or be procured at once when need is, and administered by some member of the family while waiting for the physician. Valuable lives might thus be saved.

We sincerely hope these facts may influence physicians in favor of the nitrite of amyl. At present it is a neglected drug.

THE MAYOR-ELECT OF BOSTON, DR. SAMUEL A. GREEN.

It is not often that a physician is chosen by the votes of his fellow-citizens to manage the municipal affairs of one of our large Eastern cities as its mayor. In electing Dr. Samuel A. Green to this office last week Boston has departed from the usual custom of selecting such an official from the ranks of the lawyers, the men of business, or the politicians pure and simple. In taking this unusual course there is every reason to believe that our citizens will not find they have made a mistake, and that Dr. Green's administration of the trusts about to be confided to his care will fully justify their action. Certainly no man could be better fitted by the experience of his past life, and a knowledge of the details of various departments of the city government for the discharge of the duties incumbent upon the mayor than is Dr. Green. For ten years the City Physician, he has as such become practically acquainted with the management of the Board of Health, of the various reformatory and eleemosynary institutions, with the *personnel* of the Fire and Police Departments. For a number of years he served upon the School Committee and as a trustee of the Public Library, of which he was at one time the temporary librarian.

And if we may predicate of Dr. Green wide and thorough acquaintance with the details of the present condition of the city of Boston, we may with even greater assurance claim for him an almost unequalled knowledge of all the minutiae connected with her past history, as his labors in the Historical Society amply attest. This varied experience and information in regard to local affairs are at the service of a sound judgment and personal independence of character. We believe all classes feel in regard to the mayor-elect that the interests of rich and poor alike are safe in his hands.

As our readers well know, it is neither the habit nor the duty of the JOURNAL to meddle with political matters; but many of the public interests of a large city do fall directly within the legitimate scope of our criticism and, though, unfortunately, it cannot be said that these always are, at least they certainly always

¹ Edinburgh Medical Journal, March, 1881, page 769.

ought to be, far removed from political influences. We therefore feel that we do not go outside of our proper sphere in congratulating our fellow citizens as well as our professional brother upon the result of the recent municipal election.

MEDICAL NOTES.

—The thirtieth annual meeting of the Iowa State Medical Society will be held at Des Moines, January 25 to 27, 1882.

—There are at present four cases of small-pox at the hospital. No new cases have occurred in the city of Boston for the last fourteen days.

—A great zoölogical rarity is now on view at the Jardin d'Acclimatation, Paris, in the person of a fertile mule. It is an African female mule, named Catherine. In 1874, this animal, together with a Barbary stallion, Caïd, and their offspring, Constantine, were about to be sent to the Vienna Exhibition, when they were all three purchased for the Gardens in Paris. Since then, Catherine has given birth to an offspring (Hippone), by a horse, in 1874; to two others (Salem and Othman), the sire being an ass, in 1875 and 1878; and, quite recently, she has produced a fifth (Kroumir), the issue of the same horse as her first two offspring. It is very interesting to compare together the members of this family, unique in origin. The fact of the mule being fertile positively disproves the Arab proverb: *N'har t'ouled et braia entsa out redjel outo entsa*: "When the mule produces offspring, women will become men, and men will become women." Salem and Othman are regularly used for the cars on the miniature tramway which unites Port Maillot to the Garden of Acclimatation.

PHILADELPHIA.

—Dr. E. S. Keyes, of New York, read a paper on the Treatment of Syphilis, on December 16th, before the Philadelphia County Medical Society, which tendered him a reception.

Miscellany.

DR. THOMAS B. CURTIS.

DR. THOMAS B. CURTIS, whose sudden death on Sunday, December 11th, we were called upon to record in the last issue of the JOURNAL, when we promised our readers further details of his full and well-spent life, was born in Boston, July 19, 1842, and was consequently but thirty-nine years old at the time of his death. He graduated at Harvard College in the class of 1862, and almost immediately went abroad to rejoin his parents, who had been residing in Paris for a number of years on account of the health of his father, a victim to asthma.

The first two years after his arrival in Paris were passed in a somewhat desultory manner, cultivating the language, with which he was already familiar, having as a boy attended school in Switzerland, enjoying the many opportunities afforded him for hearing good music, of which he was always fond, and in which he had

a critical taste, and even modeling somewhat in clay at the studio of his uncle, Mr. Richard Greenough, the well-known sculptor. He evinced no little natural aptitude for artistic pursuits, without deceiving himself as to the intrinsic value of these early attempts.

He began to study medicine at the Paris School in December, 1862; at first in a rather irregular way, preferring the library and the lecture-room to the laboratory and the dissecting room, and dividing his time and thoughts among many pursuits as well as going much into society. It was not for another year, when we saw him in Paris, that he had begun to acknowledge a pleasure in his medical work. To one, however, with Curtis's physical vigor and active mind dilettantism, even in Paris at the brilliant period when he was there, could scarcely prove satisfying; the love of perfection, moreover, was in his nature, and appears even in his reply as a mere child to praise bestowed upon a little drawing he had made: "Do you mean it is really good, or only good for a little boy?" He was fortunate in making the acquaintance of an advanced fellow student and *interne des hôpitaux*, now le docteur Ollivier, by whose encouraging suggestions and stimulating advice he soon sought and, in 1864, gained a position as *externe des hôpitaux*, thus becoming fairly launched on his student life. At the expiration of his service he entered the *concours* for the *internat*.

As the result of the *concours* Dr. Curtis narrowly missed being named first among a large number of applicants, and easily obtained the second position, thus gaining second choice among the hospital services. His service as *interne*, which began in 1867 and lasted the full possible time allowed, till 1872, was perhaps the happiest part of his professional life.

Among other hospitals he was on duty at the Hotel Dieu, the Loinreine, the La Ribosière under Verneuil, the Charité, the Enfants Malades where he passed two years under M. Roget, and the Necker under M. Guyon. It was during this period that he gained his very extensive and varied experience in medicine and surgery, and laid the foundation of that wide, accurate, and available acquaintance with the literature of our profession for which he was so remarkable.

At the outbreak of the Franco-Prussian war, Curtis inscribed his name upon the staff of the first ambulance to be sent to the front, but withdrew it on account of the uncertain state of his father's health, though greatly to his own disappointment. During the siege of Paris, when still at the Hôpital des Enfants Malades, he was attached to the service of M. le docteur Lannelongue, at the Palais de l'Industrie, and subsequently assisted M. le Professor Daremberg on an ambulance especially devoted to fever patients. At the close of the first siege, repairing to Versailles he offered his services to M. Delaroche, President of the Society for Aid to the Wounded at Versailles, and was under fire at the skirmish at Châtillon, and later was stationed for six weeks at Puteaux, attached, as surgeon, to an ambulance. After the suppression of the Commune, he returned to his duties as *interne*.

In his last year but one he competed with his colleagues for the silver medal, sharing with another, if we remember rightly, the first place on the list. During his last term of service as *interne* he carried off the Prix Civile, a money prize established by the celebrated Civiale, open to competition among the *internes* of the hospitals, and awarded, we believe, every four years. Curtis's thesis "*Du Traitement des rétrécisse-*"

ments de l'urèthre par la dilatation progressive" was based upon seventy cases observed at the Hôpital Necker in the service of M. Guyon, and upon these he formulated ratios of mortality and drew certain general rules as guides for operating upon urethral strictures, given various local and general conditions. This thesis, after being "crowned" by the judges, served Curtis, according to our memory, for his graduation thesis, and was published by Baillière in 1873. It was praised by the journals at the time of its publication. We were in Paris and saw much of Curtis at this period, when we may say he was at his very best, and recall with admiration the vigor, keenness, and activity of his mind.

A little later he went to England, and there made the acquaintance of Sir Henry Thompson, profiting still further by his skill and teaching in the particular branch of surgery to which so much of his recent attention had been devoted. Returning to Paris, Curtis translated two of Sir Henry Thompson's lectures for the *Gazette Hebdomadaire*, and also contributed to the same journal an account of the death from the administration of a mixture of ether and chloroform which occurred here in Boston at that time.

He took his degree in November, 1873, and about this time was elected a member of the Anatomical Society of Paris. It was now eleven years since Dr. Curtis began to frequent the medical school and lecture-rooms of Paris, and of this time he had spent at least nine years in serious, laborious, and successful study. He was thirty-one years of age, with a fine head and handsome figure, of very engaging and at the same time dignified manners, charming in conversation, and as a physician *teres atque rotundus*, at least as far as it was in the training of a famous medical centre and of the hospitals of a great city to make one so.

The death of Dr. Curtis's father in 1874 decided the family to return home to Boston, and he himself, notwithstanding the temptations which his education and position offered to establish himself in Paris, preferred to come home with them. He accordingly came back to Boston in September, 1874, after an absence of twelve years, realizing that he had again to *faire ses preuves* and begin his professional career at the bottom of the ladder.

His life since his return is better known to our readers. He was appointed as surgeon to out-patients at the Massachusetts General Hospital in 1875, and in October, 1875, was married to Miss Lovering, the eldest daughter of Mr. J. S. Lovering, of Boston. Almost immediately after his return home, in September, 1874, Dr. Curtis was appointed by the Boston Board of Health upon a committee to examine and report upon the causes and prevention of the high rate of mortality which had prevailed in the city for some years previously. The committee, which consisted of Drs. Buckingham, Ellis, Hodges, and Green, chose Dr. Curtis as its secretary, and the report handed in a year later, on November, 1875, was, as the other members of the committee state in an accompanying letter to the Board, the work of Dr. Curtis alone. It is unnecessary to dwell upon the remarkable ability and clearness of this extended report, as it was widely read at the time of publication by those immediately concerned, and is even now in occasional demand from distant cities.

Dr. Curtis became a member, and a very active one, as their proceedings show, of all the prominent medical

societies of Boston, as well as of the State Medical Society, — among these we may mention the Society for Medical Improvement, the Observation Society, the Society of Medical Sciences, — and also of the American Statistical Association; as was mentioned he was a member of the editorial staff of this journal; he was a trustee of the Eye and Ear Infirmary; he had a considerable and excellent private and consulting practice; was greatly in demand as a member of many social clubs and organizations; and in all his family and domestic relations was most happy and fortunate.

Last winter Dr. Curtis began to feel already that his accustomed capacity for work was deserting him, and to miss his old elasticity of mind and body. He suspended all his occupations, sailing for Europe in May. He revisited the scenes of his former triumphs in Paris, and attended the International Medical Congress in London. Both in Paris and London he was received by old and new friends in a way most gratifying to him and which would have been likely to turn the head of a man of his age with less modesty than his.

After a delightful summer he came home refreshed, and, as all hoped, to renewed activity. But in this his friends were destined to be disappointed; the spring had been bent farther than they knew, or, perhaps, than he himself at first suspected. He found himself utterly unable to grapple with his work or to fix his thoughts upon his tasks. In a moment a cloud passed over the fine mirror of his mind, and he was lost to us.

Those who knew Dr. Curtis personally know what the loss is to his friends and to our profession, and to those who had not the good fortune of his acquaintance the bare recital of the chief events of his life will give a sufficient indication. Though a good practitioner and a wise consultant he was essentially a scholar in medicine, and as such we know of no one to fill his place. His knowledge was not merely varied and profound but it was available, and to it was added a too rare facility in the use of choice and graceful English, which made it not only an instruction but a pleasure to listen to him.

Resolutions of respect to his memory were passed at a recent meeting of the Society for Medical Improvement, of which he was the first president since its reorganization; these, with the remarks made at the meeting, are to be found in another column. At the same time a committee was appointed to consider the form to be given to a suitable memorial.

Dr. Curtis leaves no children, and by his will, made before sailing for Europe, his medical books are left to the Boston Medical Library Association. Among these are many of great value, and the value of all is greatly enhanced by the copious notes and references with which their margins are profusely annotated. To another generation these will be the best memorial of his intelligent industry, but neither these nor any other thing can represent the man just as it was our privilege to know him.

GRATUITOUS MEDICAL SERVICES.

MR. EDITOR, — A few days ago one of our daily papers reported that the Boston Lying-In Hospital intended to extend its work by sending young physicians to attend all the poor women of the city in confinement at their homes without charge.

"Angels and ministers of grace defend us!" ARE

the young doctors to have another apparition to haunt them and cheat them of their just dues?

There are hosts of young doctors in this city well qualified for their work, and content to work faithfully for moderate fees among people of moderate means. But their good intentions are defeated by the excessive amount of free advice and other services given at the public institutions. "Unable to pay" means, in thousands of cases, "we will not pay for what we can have as well for nothing."

I do not believe a single practitioner in this city will deny that there is too much free (not gratuitous) medical service. I earnestly protest against any extension of our charities; on the contrary, they should be more strictly limited to the deserving poor.

Your obedient servant, EDWARD L. PARKS.

SPECIAL MEETING OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT, COMMEMORATIVE OF ITS PRESIDENT, DR. THOMAS B. CURTIS.

At a special meeting of the Boston Society for Medical Improvement, held December 14, 1881, Dr. Francis Minot, in behalf of a committee appointed at the preceding meeting, and consisting of Drs. Minot, J. Collins Warren, and George B. Shattuck, presented the following.

RESOLUTIONS, COMMEMORATIVE OF THE DEATH OF DR. THOMAS B. CURTIS.

Resolved, That the Boston Society for Medical Improvement, in recording the death of its President, Dr. Thomas Buckminster Curtis, desires to express its sense of his high standard, both moral and professional; his eminent culture and ability as a medical practitioner; his varied accomplishments; and the charm and refinement of his manners, which endeared him to all who were brought into personal relations with him.

Resolved, That we regret the loss of a presiding officer who was always prompt, efficient, and courteous in the discharge of his duties, and whose extensive and ready knowledge, remarkable memory, and facility of expression enabled him to contribute very greatly to the interest and value of our proceedings.

Resolved, That we would respectfully offer to Mrs. Curtis, and to the immediate relatives of Dr. Curtis our heartfelt sympathy in their bereavement.

DR. HENRY W. WILLIAMS moved that the Resolutions be adopted, as most admirably expressing the sentiment of the Society regarding the loss it has sustained. All who knew the unequalled attainments of Dr. Curtis, and observed the readiness of intellect which enabled him to make instant and fit application of his great knowledge, felt that he was destined to be a leader in the profession. We, of this Society, had especial opportunities for perceiving the nicety of his judgment as to the values of facts and theories, and had learned to rely, with ever-increasing confidence, on the correctness of his modestly expressed opinions.

When to these high qualities was added the dignified and graceful courtesy which adorned all his relations with his professional brethren, and which made association with him always a privilege and pleasure, we may well deplore the sudden blighting of our hopes

that many years of honor and usefulness might be allotted to him.

DR. J. C. WARREN said: As a life-long friend of Dr. Curtis I am perhaps able to state some of the peculiar features of his student life, with which many of the members are not familiar. As a school-boy and as a college student his quiet, gentle manner and studious habits did not interfere with his social relations or his popularity with his classmates. His departure for Europe on leaving college separated us for many years, and it was not until the close of my career as a medical student that, after completing a course of study in Germany, I arrived in Paris to find Curtis at the zenith of his fame as a medical student. The system of teaching in the Paris school, although not essentially different from that of other countries so far as the ordinary curriculum is concerned, has this peculiarity, that hospital appointments and other honors are open only to those who are successful in the *concours*. American students have little comprehension of the ordeal which it is necessary to endure to achieve success. The most varied qualities, both of mind and body, are brought into play in these trials of strength which are ingeniously varied to bring out the weak points of each competitor. I remember attending one examination where the student was required to deliver a public lecture on diseases of the popliteal space before professors and a public audience. Ten minutes' preparation were allowed to take notes, from memory of course, in an adjoining room. The student was then ushered into the amphitheatre, seated at a table on which was placed a piece of clock-work which required but ten minutes for the dial to complete the circle. A spring was touched by the servant as the young man took his seat and the hand began to revolve. It was not only necessary to occupy this brief space of time with remarks bearing upon the subject, but each particular department of it had to be touched upon at proportionate lengths. Too much time must not be allotted to diagnosis at the expense of pathology, and so on. At the time I have mentioned Curtis was about to compete with a few other well known stars for the silver medal which is, if my memory serves me right, awarded to *internes* in their last year but one of service. A preliminary examination, to weed out the weak ones, consisted of a written essay on some subject, three hours to be given in which to prepare it. It was not a question with these men of filling up the time, but to so drill themselves by rapidity of writing and special mental training as to deliver themselves of the maximum amount of work within the given period.

The subject selected on this occasion was the Iris! a task which Curtis, however, seems to have had no difficulty in mastering, for he distanced all his competitors and came out at the end of the series even with another man at the head of the list. In one of these examinations, that intended for competition for the internat in a list of one hundred and fifty names, his was second. Dicalafoy, whose name is well known to us all in connection with the aspirator, was one of his colleagues, but his name was no more familiar to the thousand medical students of Paris at that time than that of Curtis. Coming suddenly upon him, as I did at this period of his career, I remember well the powerful impression produced upon my mind. His highly polished manner, the modesty with which he bore his honors, his genial intercourse with friends, combined to form an ideal type. It was a privilege to

the medical profession of this city to receive such a man into its ranks. Although he has been with us but a few years, his peculiar gifts have not been without their influence upon all of us, both young and old. I shall not attempt to point out what his future might have been had he lived; we all know what benefits would arise from contact with a man who seemed to give a new meaning to that old phrase, "The scholar and the gentleman."

REMARKS ON SURGICAL CASES IN BERLIN AND VIENNA.¹

BY DUDLEY P. ALLEN, M. D.

THE cases of which I had hoped to write from Berlin were those of Dr. Hahn, of the Friedrichs Hain Hospital. In one case of movable kidney he had made an opening posteriorly, found the kidney, and stitched it to its original position, hoping thus to relieve the difficulty, and at the same time to avoid the loss of the organ by removal. The second case was one of syphilis of the rectum with very extensive ulcerations. To relieve this he made a left-sided colotomy, and by thus relieving the lower part of the intestine of its contents, and simultaneously washing it out and syringing thoroughly with iodoform, he thought he had completely cured the syphilitic ulcerations, and was about to close the artificial fistula which he had made, and allow the feces to pass per rectum. When I saw these cases he had two other similar operations, which he invited me to see, but for some reason the operations were delayed until after my departure from Berlin; so, not having seen the operations performed, and only having seen these two patients after operation, I thought it was not best for me to attempt to describe the cases, since I dislike describing anything incorrectly.

I find much to interest me in Vienna in the way of special courses, which help me to subjects I have not previously understood, and of which I think it desirable to know something. Of course I have visited Billroth's operations frequently. The chief subjects of which one hears there are "resection of the stomach," "excision of the tongue" and "thyroid gland," and the beauties of iodoform. Billroth has been exceedingly successful in his excision of the thyroid, operating with a single incision, following the anterior border of the sterno-mastoid muscle, and if the tumor is double-sided crossing the median line horizontally at the lower extremity of the incision, thus: []. By this cut on the right side he removes a double tumor without making any further incision on the left side, and without tracheotomy. He presented in the clinic eight or ten cases on which he had operated, and from the cases drew the conclusion that the operation should only be performed when the tumor was malignant or pressed upon the trachea, since the appearance of the patient was not improved.

The excisions of the tongue he performs, if one-sided, by ligating one lingual artery, or, if complete, by ligating both lingual arteries in the submaxillary triangle, and then cutting out the tongue close down to the epiglottis with scissors. I have seen the operation several times performed without difficulty, and the patients have almost all recovered. He ascribes his success to his subsequent dressing, which is to pack

the floor of the mouth full of dry, absorbing gauze, which is thoroughly filled with powdered iodoform. This first dressing may remain in place from eight to ten days, and does not become offensive. At the same time the patient is fed per rectum.

I think the resection of the stomach occupies more attention, kills more patients, and does less good than any other one operation at present. I can't give the exact status of the operation, but a short time since only one patient was living out of all those operated upon. Some have survived the primary operation, but have died of a secondary growth. They now have a new method of procedure when the tumor is found to be immovably bound down by adhesions, and that is to cut a hole in the most dependent part of the greater curvature of the stomach, and another in the jejunum, and thus enable the contents of the stomach to pass into the intestine, and also not interfere with the secretion of bile. One patient operated by this method lived and one died.

The fact that the patients die has the advantage that the operators are able to show the specimens, and demonstrate how nicely the parts are stitched together.

Iodoform is used in all dressings, and carbolic spray and dressings are wholly discarded; carbolic is only used for washing. Whether quite a number of cases of erysipelas that have recently occurred have anything to do with this method I do not know, but I presume not. I have seen Billroth use the iodoform in cold abscesses, to inject into the joint in white swelling, in caries, and in all acute cases operated upon; but so far as I have had opportunity of observing, the dressing succeeds better in excision of the tongue and rectum and cases where there is a fetid discharge than in cases of clean, fresh wounds.

Two boys have recently been operated for stone by an attempt at Professor Bigelow's method, which, by the way, is credited here to Dr. Bigelow, and not to Sir Henry Thompson. Both boys died. I only know the particulars concerning the last boy. He was ten years old. The evacuation was wholly impossible from the small size of the tubes, and the boy was sent to the ward with his bladder full of stone, and without cutting, and soon died.

TRANSACTIONS OF THE INTERNATIONAL MEDICAL CONGRESS.

It is announced in the *Lancet* that the three volumes of the Transactions of the International Medical Congress will be published and ready for distribution at the beginning of December. To non-members the price of the work will be thirty shillings, and the volumes can each be bought separately. The first volume will contain the list of members, accounts of the general meetings, the general addresses, the description of the specimens exhibited in the museum, and the transactions of the sections of Anatomy, Physiology, Pathology, and Materia Medica and Pharmacology. Volume II. will contain the transactions of the sections of Medicine, Surgery, State Medicine, Military Medicine and Surgery, Obstetric Medicine and Surgery, and Diseases of Children. Volume III. will contain similarly the transactions of the sections of Ophthalmology, Mental Diseases, Diseases of the Skin, Diseases of the Throat, Diseases of the Ear, and Diseases of the Teeth. Orders for the work will be received by J. W. Kolekman of Langham-place.

¹ Extracted from a private letter.

COD-LIVER OIL JELLY.

COD-LIVER oil jelly can easily be prepared in the following manner:—

℞ Cod-liver oil	5 fluid ounces.
Best isinglass	2 drachms.
Sugar (white powdered)	1½ ounce.
Oil of bitter almonds	4 drops.
Oil of allspice	4 "
Oil of cinnamon (Ceylon)	2 "
Water	1 fluid ounce.

Having placed the cod-liver oil, isinglass, and water in a suitable vessel over a water-bath, apply sufficient heat to melt the isinglass, then add the sugar, the essential oils having been mixed with it by trituration, and remove from the fire, stirring the mixture as it cools until it thickens. When it is cold a firm jelly will result, which will keep without spoiling for any length of time if put up in corked bottles. The consistence of this jelly is such that it may be taken in water, milk, or wine without tasting the oil. — *Pharmaceutical Journal*.

BERKSHIRE MEDICAL SOCIETY; RESOLUTIONS ON THE DEATH OF WILLIAM WARREN GREENE.

At the November meeting of the Berkshire Medical Society the following resolutions were adopted:—

Resolved, That by the death of William Warren Greene, of Portland, Maine,—who was at one time a Fellow of this Society,—we have lost a brother whom we honored for his great ability and genius, and loved for his large, kindly heart and courtesy alike to his patients and medical brethren.

Resolved, That while it is a public loss to all it will never cease to be a tender regret to many who knew him best, and long will he be mourned by his Fellows and friends of the Berkshire Society.

Resolved, That a copy of these resolutions be sent to his family as a token of our sincere sympathy, and may the God in whom we trust have them in his keeping.

Resolved, That a copy of these resolutions be printed in the town papers and also sent to the Boston Medical and Surgical Journal for publication.

Resolved, That these resolutions be placed upon the records of the Society.

A. M. SMITH,
F. K. PABBOCK, } *Committee.*

Deaths reported 2712 (no report from New Orleans): 1017 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 677, consumption 396, lung diseases 324, diphtheria 256, scarlet fever 109, typhoid fever 65, small-pox 95, diarrhoeal diseases 51, malarial fever 27, whooping-cough 14, puerperal fever six, cerebro-spinal meningitis 17, erysipelas 14, measles twenty, typhus fever two. From *scarlet*

fever, New York 59, Brooklyn 21, Philadelphia six, Pittsburgh four, Milwaukee four, Buffalo six, Boston, Chicago, St. Louis, Baltimore, and Holyoke one each, Worcester two. From *small-pox*, Chicago 33, Philadelphia 20, Pittsburgh 15, New York 12, Cincinnati seven, Holyoke four, Brooklyn, Buffalo, Milwaukee, and Lawrence one each. From *malarial fever*, Brooklyn and St. Louis nine each, New York seven, Cincinnati and District of Columbia one each. From *whooping-cough*, New York five,

Brooklyn and Chicago three each, District of Columbia two, Pittsburgh one. From *puerperal fever*, New York two, Chicago, Baltimore, Pittsburgh, and District of Columbia one each. From *cerebro-spinal meningitis*, St. Louis five, Philadelphia three, New York two, Chicago, District of Columbia, Pittsburgh, Milwaukee, Lawrence, Springfield, and New Bedford one each. From *erysipelas*, New York two, Holyoke three, Boston, Brooklyn, Philadelphia, Pittsburgh, Buffalo, Chicago, St. Louis, Haverhill, and Chelsea one each. From *measles*, New York 15, Buffalo three, Pittsburgh, and Milwaukee one each. From *typhus fever*, New York two.

In 35 cities and towns of Massachusetts, with a population of 1,010,359 (population of the State 1,783,086), the total death-rate for the week was 21.61, against 19.80 and 18.40 for the previous two weeks.

For the week ending November 5th in 149 German cities and towns, with an estimated population of 7,879,026, the death-rate was 22.9. Deaths reported 3476; under five 1536; pulmonary consumption 477, acute diseases of the respiratory organs 292, diphtheria and croup 194, scarlet fever 130, diarrhoeal diseases 111, whooping-cough 64, typhoid fever 56, puerperal fe-

ver 24, measles and röteln 23, small-pox (Aachen) three. The death-rates ranged from 13.1 in Halle to 49.2 in Duisberg; Königsberg 22.5; Breslau 25; Munich 30.1; Dresden 26.7; Berlin 23.6; Leipzig 23; Hamburg 21.5; Hanover 22.9; Bremen 21.9; Cologne 25.5; Frankfurt 16; Strasburg 22.7.

For the week ending November 12th in 149 German cities and towns, with an estimated population of 7,915,940, the death-rate was 23.8. Deaths reported 3628; under five 1705; pulmonary consumption 480; acute diseases of the respiratory organs 320, diphtheria and croup 198, scarlet fever 134, diarrhoeal diseases 127, whooping-cough 61, typhoid fever 54, measles and röteln 30, puerperal fever 21, small-pox (Königsberg, Dresden, Berlin two, Aachen three, Essen) eight, typhus fever (Thorn) one. The death-rates ranged from 14.2 in Stuttgart to 35.5 in Frankfurt A. O.; Königsberg 22.9; Breslau 32.1; Munich 26.7; Dresden 23.6; Berlin 26.1; Leipzig 19.9; Hamburg 24.4; Hanover 16.1; Bremen 16.4; Cologne 25.9; Frankfurt 17.1; Strasburg 24.6.

The meteorological record for the week ending December 10th in Boston, was as follows:—

Date.	Barometer.	Thermometer.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF OFFICERS OF THE MEDICAL DEPARTMENT U. S. ARMY, FROM DECEMBER 10, 1881, TO DECEMBER 16, 1881.

McClellan, Ely, major and surgeon. Relieved from duty at Fort McHenry, Md., to proceed to Fort Trumbull, Conn., and relieve Assistant Surgeon W. H. King. S. O. 224, Department of the East, December 15, 1881.

King, W. H., captain and assistant surgeon. When relieved by Surgeon McClellan to repair to Fort McHenry, Md., and report for duty at that post. S. O. 224, C. S., Department of the East.

Ladd, J. V., captain and assistant surgeon, McPherson Barracks, Ga., before complying with paragraph 3, S. O. 124, C. S., Department of the South, granted leave of absence for one month, with permission to leave the Department. S. O. 146, Department of the South, December 8, 1881.

Horr, J. V., R., captain and assistant surgeon. Granted leave of absence for one month. S. O. 222, Department of the East, December 12, 1881.

Perley, H. O., captain and assistant surgeon. Having reported in person at these headquarters, will report to the commanding officer, Fort Columbus, New York harbor, for duty as assistant to the post surgeon and attending surgeon at these headquarters. S. O. 224, C. S., Department of the East.

Grogan, W. C., first lieutenant and assistant surgeon. Granted leave of absence for one month, with permission to apply for

an extension of one month. S. O. 150, Department of Texas, December 3, 1881.

BOOKS AND PAMPHLETS RECEIVED. — The Opium Habit and Alcoholism. A Treatise on the Habits of Opium and its Compounds, Alcohol, Chloral Hydrate, Chloroform, Bromide Potassium, and Cannabis Indica, including their Therapeutical Indications; with Suggestions for treating various painful Complications. By Dr. Fred. Herman Hubbard. New York: A. S. Barnes & Co.

The Surgery of the Pericardium. By John B. Roberts, M. D., of Philadelphia. (Reprint.)

Atlantic City as a Health Resort. By Boardman Reed, M. D. Second Edition. (Pamphlet.)

Transactions of the New Hampshire Medical Society at its Ninety-First Annual Session, held at Concord, N. H., June, 1881.

Recent Progress in Surgery. Report to the Wisconsin State Medical Society. By N. Senn, M. D., of Milwaukee. (Reprint.)

Medical Expert Witnesses. Read before the Union Medical Association of Berkshire, Bennington, Rensselaer, and Washington Counties, at Hoosick Falls, N. Y., October 12, 1881. By John Lambert, M. D., Salem, Washington County, N. Y., Retiring President. Published by request.

Nihilism in Medicine. An Address delivered before the New Hampshire Medical Society, June 21, 1881. By D. W. Jones, M. D., of Portsmouth. (Reprint.)

Lectures.

A CLINICAL LECTURE.

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK, OCTOBER 12, 1881.

BY PROF. A. JACOBI, M. D.

WET NURSES; IRREGULAR DENTITION; DIPHThERIA; RACHITIS.

THIS woman is expected to take the place of a wet-nurse, and I have taken the opportunity of presenting her to you with her child, in order that I might say a few words on a very important subject. In choosing a wet-nurse one of the first things that you ought to do is to look at the baby of the woman who presents herself for the place. I will show you some changes in this baby which look suspicious. Hereditary syphilis is very common in a great city, and of course in case you were to discover it in the child you would not engage its mother as a wet nurse, for although the father might infect the child without the mother, yet the disease would be communicated to the mother afterward through the medium of the child. Hereditary syphilis usually develops during a period included between the fourth and eighth week of life, but its development is sometimes retarded until after the third month. One of the first symptoms of syphilis is roseola, or, if not that, a yellow discoloration of the skin attended by desquamation. Another very common symptom is the appearance of fissures around the mouth and anus, rhagades, as they are termed. One of the earliest symptoms, at birth or a few days after, is a pemphigus which affects the palms of the hands and the soles of the feet, also psoriasis occurring in the same localities. Such affections as these do not necessarily mean much in later life (unless they are palmar, when they may be attributed to syphilis). When they are general they are not of syphilitic origin. Even if after examining a child you were to find only what may have been the results of such local affections, such as a little discoloration and desquamation, you ought to be on your guard, for it may be that the child has had anti-syphilitic treatment, and has partly recovered. Now this baby has suspicious spots on the palms of its hands and some soreness there. The mouth and anus appear to be free from any appearance of rhagades, but there are spots of desquamation on the feet, although not so bad as on the hands. Now in the presence of such symptoms as these it is necessary to decide whether or not this child is syphilitic. If she is the mother cannot be recommended as a wet-nurse. The mother says that the child has only had these red spots of desquamation a week or two, and it is also reported that she has had little blisters over her body, prickly heat she calls it. The child has not been under treatment at all, and there appears to be no other symptom of syphilis except this peculiar appearance on the palms of the hands. There is no coryza nor roseola, nor has the child ever suffered from anything of the sort, nothing else besides these suspicious-looking spots and this desquamation. Is this syphilitic or not? It seems to me that it is not, because, as the child has had no treatment, if hereditary syphilis were the cause of these spots it would have given origin to other symptoms besides. There has been a great deal of solar eruption lately, and after that the skin is apt to

peel just as it has done here. As far as the hands are concerned the occurrence of such phenomena, then, are certainly suspicious, but remember that in the young infant and fetus the flexor muscles are far more active than the extensors, and the flexion amounts sometimes to almost a contraction. If you allow a child to take hold of your finger it grips it with an almost convulsive grasp. Now the nails of this baby are rather long, and when its flexors contract the nails are driven against the palm of the hand, and this has, I think, been the cause of the psoriatic appearance in this situation. I think that the long nails on what are also unusually long fingers account for this condition of things, and I conclude from the absence of any other symptoms that it is not of syphilitic origin, and it is accordingly safe to recommend this woman as a wet-nurse.

Here is a case which I have brought before you because it gives me an opportunity to say something to you about irregularities of dentition. This child is eleven weeks old, yet it has two molar teeth which were noticed before it was five weeks old. The mother says that she noticed the first molar tooth before the child was one month old. It appeared in the left upper maxilla, and the day afterward another molar tooth was found to exist opposite in the lower jaw. This is a very peculiar history. There is nothing else the matter with the child, the mother says, and all her other children are in a normal and healthy condition. Now you know that it is very uncommon to find molar teeth developing as early as they probably have in this case. Teeth will usually appear about the seventh or eighth month, but then it is the *lower* central incisors. You remember in the case of premature cranial ossification which we had the other day, I made the point that it was the upper central incisors which had appeared first, there being a closer connection between the skull and upper jaw than the skull and the lower jaw. Here the appearance of teeth at all at so early an age is quite abnormal, and it is quite probable that they were there before the mother noticed them. They may and probably have been congenital. Congenital teeth are very small, and occur very rarely. I myself, as I am in an exceptionally favorable position to observe such anomaly, have met with that anomaly perhaps twenty times. This is quite an unusual number, for there is many a practitioner who never met with a case. But a congenital molar tooth I have never seen, nor do I know of any that has been reported. There have been many cases of congenital teeth recorded, probably because of their rarity, and the history of congenital teeth is very old. Pliny the younger states that the celebrated Marcus Curins, consul of the Roman Republic two hundred and seventy years before our era, had a full set of teeth at birth. This was the reason of his being named Dentatus. The same author mentions two other instances of children who had their teeth at birth. Zoroaster, the Persian legislator, is reported to have had all his teeth at birth. Louis the Fourteenth of France was born with two teeth, as was also his secretary of state, Cardinal Mazarin. Richard the Third of England and Mirabeau both had congenital teeth. Haller has collected a list of nineteen cases of congenital teeth, and there are many other instances of this abnormality, besides these which I have mentioned to you, which are recorded both in ancient and modern literature. The journals of the last ten years continue to give a number of such

cases. These congenital teeth are usually small, ill-shaped, and have no root. They only hang in the gums. They differ from genuine teeth in that they are less firm and solid, their enamel is thin, and not formed at all in some places, and they are not inclosed in the dental alveolus. Such teeth often prevent the child from nursing, and cause the nipples of the mother to become very sore. They should then be removed, which can be done without difficulty. Often an ordinary dressing forceps will be sufficient for the purpose, or they may even be detached by the finger. When such teeth are removed the real deciduous teeth, as a rule, appear afterward. In a number of cases which I have followed up new temporary teeth have appeared, although it has been stated, erroneously, that no temporary teeth would appear at all previous to the eruption of the permanent teeth. These congenital teeth seem to be entirely supernumerary, and I regard them as an accidental connective tissue formation. The upper tooth here is too firm to justify an attempt to remove it at present. The lower molar I was able to remove with my finger. There is one fact about congenital or abnormal teeth which it is important that I should mention. The children are often not in good health. They are cases in which rachitis develops at a later period, and may usually be considered a symptom of a morbid constitution, which will require anti-rachitic or anti-scorfulous treatment for its repair. It is then an anomaly which is by no means welcome. Premature dentition, premature walking, and premature ossification of the cranial bones usually coexist.

Another variation in the appearance of teeth is their eruption at a period later than the normal one. One case is on record where a girl got her four temporary teeth when thirteen years old; another where a child of five or six years had only a few incisors; and there is a case reported by Smellie where the first tooth appeared in the twenty-second year of life. There are a very small number of cases in which the entire absence of teeth has been noted; also where certain of the teeth have been absent. Storch describes the case of his own daughter who had no canine teeth, and I myself have seen a lady with but two upper incisors, and lately a few children in the same family with the same anomaly. The molar I present here is very flat, its surface large enough, its depth very trifling; it shows four little prominences representing the diminutive roots. If you care to read more on the subject I refer you to my *Dentition and its Derangement*, New York, 1862, or the *American Medical Times* of that year.

Our next case is that of a boy five years of age who was attacked yesterday with vomiting and sore throat. His temperature, at present, taken in the rectum, is 101.5° F. He complains of some pain on swallowing. The left tonsil is slightly, the right considerably, enlarged, and there are a few little spots of whitish gray discoloration scattered over each. The question is What do they signify? The tonsil is not a uniform body, but is a conglomeration of ten or twelve follicles glued together by very dense connective and elastic tissue. The ducts of the follicles may be enlarged by former inflammation. Now in such a duct, a large amount of epithelium accumulates and fills up the duct instead of being removed, because the enlargement has transformed what was a duct into a bag, and as there is a tendency to suppuration in tissues which have been modified by disease, you may have as a result of the

mechanical pressure an abscess in the tonsil. Such abscesses occur frequently, and the same process may recur again and again in the same tonsil, though in different follicles. When suppuration does not take place and the contents of the dilated ducts are not expelled, they dry up and form cretaceous masses which have been called tonsil stones. Now it is of the utmost importance that this disease, which is local and occurs only in the follicles, should not be mistaken for a disease which is far more dangerous,—I mean diphtheria. To day there may be only these few white spots visible, but to-morrow, if the disease is diphtheria, they will have coalesced, and there will be membrane, therefore you should be very careful to make the distinction at once. If these spots are membrane then we have not to do with the local disease known as follicular tonsillitis, but diphtheria. There is one fact in regard to follicular trouble which is perfectly characteristic and will enable you to make your diagnosis with confidence. In that disease, if you take a fine probe, you will be able easily to run it into the dilated ducts of the follicles from one sixth to half an inch or more. In diphtheria you cannot. The spots there need not correspond with the follicles, and will not admit the probe, and you have no right ever to make a diagnosis of follicular tonsillitis unless you can run your probe into the ducts, which in that case will be very easy to do.

It is not possible to do that in this case and this boy has, therefore, diphtheria; not severe now, certainly, but it may be to-morrow. Every case of that disease ought to be looked on as severe. Cases which look well now may totally change in the course of a few hours. Those cases which are looked after from hour to hour, in the large majority of instances, get well, when they are neglected and not seen frequently their chances are much worse.

The lymphatics of the neck are enlarged only when the disease has invaded the nares or pharynx, never when the tonsils alone are the seat of the disease. Diphtheria of the tonsils is usually a mild disease, but needs, as I have said before, careful watching, as there is no telling where it may extend. This boy must be isolated. He ought to be in an upper story, because infection can be prevented more easily in that case, as the contagious principle of such diseases will go upward with the current of warm air. I should apply ice to the glands if they swell. Let him take a dose every twenty minutes of a prescription containing chlorate of potassa, tincture of the chloride of iron, glycerine, and water. It is important that he should have the benefit of the local application frequently and by giving it in this way you are constantly washing those infected tonsils with the chlorate of potassa and iron. In the night he ought to be waked up every hour for the medicine. A sleep of six or eight hours is too long, as in much less time diphtheria may develop into a serious and, perhaps, fatal attack. If he is awakened every hour he will fall asleep almost immediately after.

Here is a child which is two and one half years old, and which commenced to walk when it was eleven months old. It walked very well until three months ago, when the mother says that it fell frequently. She throws the left foot in front of the right and then trips over it. She cut her lower incisors at the age of six months and three months after the upper. The mother says that she had all her teeth at sixteen months, but that is not probable. When she was one year old she had an abscess under her jaw, but has never had any

continued illness. If you examine the lower limbs you will find, as I do, that the epiphyseal ends of the bones are thickened and their shafts curved. If you put the child's heels together you will notice that the knees do not touch, but spread widely apart. The femoral bones are curved outward and forward, and it is owing to this deformity that the child trips. The curvature of the bones causes the stumbling and is the result of rachitis. Rachitis is a constitutional disease, one of the symptoms of which is a softening of the bone, and an undue development of fat. It is also marked by a lack of muscular development, to which one symptom of the disease is due, obstinate constipation, concerning which you have often heard me speak. One of the first symptoms of rachitis is that which I am able to show you in this case—the diaphragmatic groove. It is this groove which you see around the lower part of the chest, and is a direct result of softening of the bones. Rachitis shows itself in all the bones, both long and flat, particularly in the occipital portion of the cranium. You remember, perhaps, a case of the kind in which the bone had been absorbed in numerous places until it seemed as if a firm pressure with the finger on the soft spots would penetrate into the cranial cavity. Often this absorption continues until the thickness of the cranial bones is no more than a sheet of paper. This absorption takes place usually on the occiput and the parietal bones, that being the portion of the head which rests upon the pillow. The question is, now, What can be done for this case? As a rule cases of this kind go on without attention until it is too late for treatment to be of any service. If they come before the irregularity is very great, and receive appropriate treatment, they have a chance of outgrowing the deformity, for a curve which is very marked when the bone is short will, as the bone grows longer, be much less in proportion to the length of the bone. This child should be well fed, and by that, I mean it should get plenty of beef, eggs, barley, oatmeal. For medicine, it ought to get some preparation of iron, as the iodide and the salts of sodium and calcium, in fair quantity. It ought to be regularly bathed and have plenty of air, for many cases of rachitis owe their origin as much to bad air as to bad feeding. At present, it is not the time for us to consider the propriety of surgical interference for remedying the deformity.

RÖTHELN.

BY C. M. JONES, M. D.

AMONG the mooted points in nosology the *rötheln* question still remains conspicuous. Is there an independent exanthem which deserves this name or are all the cases which receive it more properly classed as hybrids or modifications of other universally recognized conditions? Many authorities, including the *Index Medicus*, do not admit it or refer to it. I purpose in this paper to report a few cases which have come under my observation, and then to consider wherein they may be distinguished from various allied forms of disease.

Case I. January 21st. Anna H., age twenty one, came to my office, having been well till yesterday, when she had a feeling of weariness, malaise, and want of appetite. Has had recently some diarrhoea, also

soreness of throat. To-day noticed that her face was quite red, and eyes swollen, and soon after there appeared on the forehead and face a rash which speedily extended over the neck and upper part of the body. This consists at the present time of thickly-scattered blotches, in shape rounded or slightly irregular, slightly but distinctly elevated above the surface of the skin, in color pale red, the centre darker than the periphery, the skin between unaffected, nowhere crescentic in arrangement, and suggesting measles only to a superficial glance. The blotches vary in size, nowhere coalesce into large patches; the throat is inflamed, both tonsils red and swelled, the right the most so; cervical glands enlarged on both sides; no cough or sneezing or any marked catarrhal symptoms; eyes feel weak, and are lightly injected; tongue coated; has had measles; pulse 120; temperature 102° F.

January 22d. The rash has extended itself quite rapidly over the body, and now appears to a moderate extent on the extremities; on the face it is diminishing. Patient is nearly free from fever, the throat improving, and the next day, the 23d, she was entirely well.

Case II. January 22d. Sarah T., age eighteen, rose yesterday with headache, and during the day had a feeling of weakness and discomfort. Slept well last night, and on rising this morning noticed for the first time a rash on the face, which consists of rounded, slightly elevated papules, in afternoon extending all over the trunk, and barely manifest on the extremities; here and there the blotches show a tendency to run into each other. Has had no cough, no coryza, no sore throat; no glandular swelling noted; thin white coating on tongue; had measles two years ago; pulse 119; temperature 101° F.

January 23d. The rash to-day more marked on the limbs and fading on the body; has no fever, and feels fit to work.

Case III. Mary D., age ten, has had cold and cough for some days, which has not grown worse; night before last she seemed rather feverish; has not had any irritation of the eyes; has a little running at the nose; does not complain of sore throat; there appears on face and body a rash similar to that already described, but more scattered; throat is reddened; glands not affected; had measles two years ago; pulse 95; temperature 99° F.

January 28th. The rash is general over the body, but the individual papules quite isolated, and the color throughout has been paler than in either of the previous cases. In forty-eight hours from the beginning of the eruption she retained only the symptoms of the cold from which she had been several weeks suffering, but otherwise was quite well.

Case IV. December 20th. Alonzo E., age ten, after a day of malaise, lack of appetite, and much thirst, woke up this morning with face suffused, eyes red, inclined to water, and a rather bright red rash, distinctly papular, varying in size from one fourth inch down to a pin head, generally round, the edges more or less irregular, and reddish lines here and there, extending from one papule to another, and many papules coalescent; tongue has a heavy white coat; throat not affected; occasional sneezing; no cough; skin burning; glands enlarged; pulse 120; temperature 102° F. Stays in bed, and looks and acts quite sick. The next day felt a little better. Temperature 100° F.; tongue clearing, tip reddened and papillated; rash on face

growing paler, on the legs still very bright, though nowhere so bright as in the face yesterday.

December 22d. Temperature 99° F.; remnants of rash in face still seen, and quite distinct elsewhere; feels comfortable except for weakness.

December 23d. Traces of the eruption could still be made out on careful examination. This boy had measles with unusual severity under my own charge two years ago.

Case V. February 11th. Herbert R., age thirty-two, was at his business yesterday in usual health. On rising to-day the mirror revealed an eruption on his face, but aside from this he complained of absolutely nothing; throat not affected; nothing but his face would suggest to him that he was not well; pulse 90; temperature 101° F. The course of this rash was similar to the others except that it remained visible one day longer; appetite was good throughout; would not have remained from his business had he not been so directed; had measles in childhood. His two children, aged seven and two, respectively, who were much in the room with him, and had never had measles, remained perfectly well, and took measles after a brief exposure five months later.

Case VI. Josie R., ten years, has been for some weeks ill of anæmia and chorea with mitral regurgitation; has not varied much in her condition till last night, when she became hot and sweaty, but was not chilly. This morning her cheeks and eyes were very red, skin hot, and soon after her mother noticed a bright red efflorescence all over the face and body, that on the face being most intense. The rash in the afternoon was made up of easily felt, distinct papules, thickly scattered, none exceeding one fourth inch across, mostly smaller; the delicate skin between is suffused; there is no coryza; no cough; some lachrymation and injection of the conjunctiva, and the eyelids and face seem somewhat swollen; throat hyperæmic and irritated; rather hoarse; tongue furred, tip red and papillated; had measles two years ago; has not had scarlet fever; pulse 125; temperature 102.6° F.

December 3d. Pulse 90; temperature 100° F. The general redness of face has disappeared, leaving the blotches, which are absolutely fainter, relatively quite as distinct; they run into each other at many points; on the body the eruption is brighter and confluent over large tracts, with islands of clear, white skin contrasting strongly with the duskiess of the efflorescence, the borders everywhere being quite abrupt; condition of arms and legs similar; has some vomiting and diarrhoea; inflammation of throat diminishing; the red and papillated condition of the tongue more marked.

December 4th. Pulse 85; temperature 101.8° F.; feels somewhat better, but has headache, and the diarrhoea continues; eruption for the most part has left the face, and elsewhere is fading rapidly; throat normal; choræic twitching said by mother to be frequent, but none seen at the visits.

December 5th. Pulse 85; temperature 102.1° F.; respiration lab; passed a sleepless night on account of headache and general soreness, which seems to be rheumatic in its nature; rash entirely gone; tongue red, coated.

December 6th. Pulse 115; temperature 100.2° F.; some vomiting; continues of pain in right elbow and back of neck; some tendency to cough.

December 9th. No fever; no pain; pulse 90; is now affected only as before the rash; no desquamation noticed.

Cases VII. to XII. December 25th I saw a girl of six years, who was the first of a series of six cases, all occurring in one family. The child was running round, not much disturbed, and the mother had sent, not because the symptoms demanded a physician, but there were sore throat and a strange rash, not looking like measles, and she wanted to know what was the matter.

One week later (VIII.) a brother of twelve and (IX.) a sister of eight, and two weeks from the first cases (X., XI., XII.), three sisters, aged respectively ten, four, and one, were taken. All these children went through about the same course. The cases were all mild; the elevation of temperature was not more than one and one half degree; all had sore throats; all had enlarged cervical glands; all had papular rashes of precisely the same type, in the scattered form, lasting from two to three days; none of them had cough or coryza, injection of face or eyes; none of them took to bed.

All of these children had had measles, three of them six years, one four years, and two six weeks before, and three had scarlet fever five years before.

These cases taken together have very little resemblance to roseola, as ordinarily defined, or to scarlet fever. In only one, No. VI., would there have been a possibility of confusion, and that only on the second day. Nor do I think that even then a mistake would probably have arisen unless the observation were careless or confined to a very limited portion of the affected surface. But they are similar in certain respects to measles, and it is from this that they are to be distinguished if at all.

At the outset, it may be asked why, if this is an exanthem *sui generis*, has it been so long overlooked or disallowed? To answer this question satisfactorily, we need only consider the nature of the disease and the mode of scientific development. The duration of the disease is short, its course is mild, and it seems of very little importance. It does not come to the hospital, it does not demand therapeutic interference, it does not summon the physician. An intelligent layman will recognize the novelty of the attack as compared with scarlet fever or measles, and may seek an expert diagnosis. But there needs no second call. Subsequent cases of uniform symptoms and uniform mildness pass unobserved, and hence it is either reckoned a mild case of measles, or regarded as a sporadic doubtful condition when, in reality, it may be but one example of an extended epidemic.

Further it is the characteristic of inductive reasoning, advancing slowly, to recognize new distinctions and to draw boundary lines more sharply. Formerly variola, scarlet fever, and measles were regarded as different manifestations of the same disease, and their complete differentiation has been the work of generations. And in the same way, when, a little more than a century ago, De Bergen first described *röthein* as an unrecognized exanthem, he found few followers. But the number of these has constantly increased till now the leading authorities in diseases of children and dermatology, both at home and abroad, are almost unanimous in accepting its individuality.

There are two laws of disease, conformity to which is sufficient to establish specific identity, first, the law of contagion, second, the law of immunity.

If exposure to a given disease is followed by a repetition of that disease, and not by any other, it has a distinct individuality. If the subject of a given disease is

thereby protected from a repetition of that disease and not from the attack of another, it has also a distinct individuality.

Both these dicta are in the main true of variola, measles, and scarlet fever, and I think we shall be able later to add röteln. Each of the first three propagates its own kind, and repetitions of each, though universally admitted, are relatively rare and by no means sufficient to contravene the general law. But if we subsume under the name measles all this large class of cases of which I have given a sample, we must give up this statement, and say that repeated measles not only is not rare, but rather to be expected. And while admitting secondary attacks of measles, as I do, I may be here allowed to express the opinion, that many cases which are so considered would, if more carefully examined and followed, be found to be cases of the sort herein described. Further, the observation in the epidemic form of a large number of such cases has demonstrated that the so-called röteln reproduces itself if anything, and never by any chance either measles or scarlet fever. And in this series, when we consider the activity of the measles contagium, we can hardly think that the children of Case V., with every possible exposure, would have escaped some form of the disease, if we really were dealing with measles. Their susceptibility is shown by their subsequent infection after a very limited exposure, and the same is true of children in the house with Case II., and in Cases VII. to XII. all the children had exactly the same conditions, developing one and two weeks after the first, and it is not reasonable to suppose that the peculiar type would have been so well defined in each case, that deviations from it, or approximations to the ordinary form, would not have occurred had these really been cases of measles.

These observations lead to the conclusion that the contagiousness of this particular form of disease, as compared with measles or scarlet fever, is slight, but it is undoubted, and the repetition in the same person has been seldom observed. Also measles and scarlet fever may precede this condition, or, according to one observation of my own, as well as many reported in the journals, may also follow it without any special modification. Neither affords any immunity from attacks of the others.

Cases VIII. to XII. give suggestions as regards the incubation, two coming down one week and three two weeks after the first. These would probably be the minimum and maximum periods of incubation. All these cases may have had other exposure except No. XII., the infant, for they were in school, and all the neighboring children were said to be similarly affected; but for the infant the time is definite, no other exposure being possible.

It remains only to point out the resemblances and differences between measles and röteln, which are near allied and most often confounded, for, as regards scarlet fever, there can hardly be much confusion.

RÖTELN.	MEASLES.
INCUBATION.	
About two weeks.	About ten days.
PRODROMATA.	
Often none. Patient may be well till the rash appears. Sometimes a feeling of malaise, now and then some nausea and sneezing. May have a slight coryza. Fever slight or none.	Usually well marked. Lassitude. Catarrh. Lachrymation. Dry, frequent cough. Hard, rapid pulse. High fever.

DURATION OF PRODROMATA.

If present, one or two days. Four days.

STAGE OF ERUPTION.

Erllorescence appears at once on the face and upper part of the body. Is abrupt and over a pretty large area. Extends rapidly.

Generally in small, quite distinct papules, irregularly rounded, varying in size from a pin-head to one fourth inch across. Skin between unaffected. More distinctly elevated to the feel. Never crescentic. Often confluent over a considerable area, which will be of even color, with islands of clear skin, with edges sharply defined.

Pale or rather bright red. The centre often darker than the periphery.

Fever with the rash, if at all. Often almost none; not so high as in measles. Rarely above 101° or 102° F. Temperature curve not characteristic.

Erllorescence more localized at first appearance on neck and face, and spreads gradually.

Generally red dots, at first separate, running together in a crescentic form, seldom confluent over a large area.

Color apt to be darker, in a severe case often becoming purple.

Fever before the rash, and increasing steadily till it appears; generally high. Never absent. Temperature curve in an uncomplicated case quite characteristic, having two maxima, one before the rash, and again in its florition.

DURATION OF RASH.

Fades in from twenty-four to forty-eight hours. Rarely lasts three days.

Fades on the fourth day.

ACCOMPANYING SYMPTOMS.

Sore throat frequent. Occasional hoarseness. Conjunctiva only slightly affected. Enlargement of the cervical glands quite general. Catarrhal symptoms slight. Bronchitis absent.

Severe irritation of the mucous membranes. Congestion of conjunctiva the rule. Bronchitis universal.

DESQUAMATION.

Generally absent.

Generally present.

SEQUELÆ.

None.

Diseases of the respiratory tract common; also affections of the eyes.

In conclusion, then, röteln deserves to be regarded as a specific exanthem:—

- (1.) Because of its contagious reproduction of itself.
- (2.) Because it does not afford immunity from any other disease, nor does any other disease afford immunity from it.
- (3.) Because of the peculiarities of the eruption.
- (4.) Because of the peculiarities of the temperature.
- (5.) Because of the absence of desquamation.
- (6.) Because of the absence of sequelæ.

And I may further add that in a personal experience of some seven hundred cases of measles I have seen none exhibiting such deviations from the normal type that I could fairly link with them the dozen cases I have reported to-night.

—The advertising columns of the *Lancet* give notice that the surgeons of the Royal Westminster Ophthalmic Hospital will attend daily at two P. M. to give instruction in the use of the ophthalmoscope to practitioners. The ophthalmoscope is becoming of greater value every year for the diagnosis of nerve and other diseases, and the *Lancet* hopes this effort to disseminate the knowledge of its use will be cordially responded to.

A CASE OF FRACTURE OF THE SKULL FORTY CENTIMETRES IN LENGTH, RESULTING IN DEATH FORTY-TWO DAYS AFTER, FROM ENCEPHALITIS AND PYEMIC INFECTION.

BY MARSHALL L. BROWN, M. D., BRIGHTON.

On the afternoon of December 18, 1879, J. A., a blacksmith weighing two hundred and sixty-eight pounds, while riding at a break-neck speed in an open buggy, collided with a coal cart, and was thrown out, striking the top of his head upon some part of the cart, producing a bruise upon his scalp, extending diagonally across the head from the left frontal eminence to the right parietal bone, a severe concussion and injury to the brain, and fracture of the skull.

He was found senseless, bleeding from the nose and mouth very freely, losing a large quantity of blood. He lay, quietly, where he had fallen, without moving save a slight spasmodic motion of the legs, and his breathing was scarcely perceptible. After a few moments he was taken into a house near by, and Dr. Hazelton, of Grantville, saw him. In the course of an hour he regained his consciousness so as to answer questions and soon after said he was cold. A suitable conveyance was procured and he was taken home, a distance of six miles. On arriving, with the assistance of a man at each arm, he walked from the wagon into the house, up a long flight of stairs to his bedroom. I was then called, saw and examined him with Dr. Hazelton. He was undressed, in bed, lying partially upon his left side, breathing somewhat noisily, and blood was trickling from his nose and running down his throat. There was a bruised line half an inch in width and four to five inches in length on the top of his head; the scalp in the vicinity of this bruise was swollen and the swelling extended to the eye, which was very much swollen, protruding, and black; blood had settled beneath the eye, and the bridge of the nose was also contused and swollen. He was in a half-conscious condition; on questioning him, he described the accident, and answered correctly all questions. He complained only of the back part of his head and neck when he was moved. Twelve hours after the accident he vomited nearly a quart of blood which he had swallowed.

The second day, January 19th, there was a higher temperature, quicker pulse, and later in the evening a flushed face and hot head; at 11.30 p. m. he had a very severe convulsion involving both sides of body; at twelve he had a second convulsion, lasting twenty to thirty minutes, from which he passed into a comatose condition. His pulse was full, hard, and bounding. I brought him quickly under the influence of veratrum viride, bringing his pulse down to eighty. Temperature was then 102.2° F. For the next ten days his pulse was kept near that number, and his temperature became normal. After the convulsions there was considerable difficulty in swallowing, the left side of the mouth was awry, the tongue pointed to the left, the left eye was immovable, the pupil constantly dilated and insensible to light, and the whole left side of the face presented the peculiar expressionless appearance indicative of paralysis. He called his milk cider, his broth whiskey, the sense of smell seemed much diminished if not wholly lost; and there was loss of hearing in the left ear. He continued in a semi-comatose state for sev-

eral days; could be roused from it, when he would for a few moments seem himself, would then relapse into a mild delirium and talk of his business or amusements.

On the sixth night after the accident, the nurse watching him said that twice during the night, while apparently sleeping quietly, he straightened out his legs and arms, and a slight trembling passed over his body; he made no noise, there was no difference in breathing that he noticed, and there was no increase of heat in the head, or any change of color in the face; both times the action was but momentary. The next morning I found the paralysis in the parts above named more complete, and for twelve hours he could not put out his tongue, or swallow anything, choking in an alarming manner if he attempted it. He had no control over his mouth, the fluids offered him would run out of the corners, and finally he refused to take anything. His left arm was also paralyzed. In the course of the following night and the next day he managed to swallow a little liquid, spilling most of it however.

December 26th, Dr. Z. B. Adams of Framingham was called in consultation and diagnosed a fracture of the base of the skull, and gave an unfavorable prognosis; but said "under certain conditions, there was a possible chance of recovery." Then was noticed for the first time a fetid odor coming from his nose and mouth. After the bleeding had stopped he had had a clear, almost colorless, fluid running from his nose requiring the constant use of a handkerchief. From December 24th to January 9th his pulse ranged from 80 to 100. Temperature did not vary much from normal, being 98.6° F. on the 9th. The 5th, 6th, and 7th he was more restless and delirious, and not as easily controlled. On the 8th both eyes were more injected; up to this time the left eye had been constantly dilated, and did not respond to light, the ball itself being perfectly immovable. January 10th, three weeks after the accident, pulse was 88 and feeble, temperature 98.6° F. Hands were cold, presenting a mottled appearance. For a few nights, 10th, 11th, and 12th, he had sinking spells; hands white and cold, pulse feeble and face pale, temperature below normal. Food, stimulants, and friction relieved these symptoms somewhat. January 13th. Pulse 88; temperature 97° F. He passed a very restless night, wanting to go home, asking for his pants, asking if he was in for life, etc.

January 14th to 16th seemed to improve, slept more quietly, and was more rational. On the morning of the 16th, pulse 100, he had had a very good night; after taking his breakfast, slept soundly all the forenoon. He awoke about two p. m. and was perfectly rational, called his wife to him, kissed his little daughter, arranged his business affairs, and then advised his wife what to do after he was gone. He was asked where he was going and replied: "Going from whence there is no return;" he then said his head felt very badly, and kept constantly putting his hand to it saying "no one could know the suffering he had in his head." I saw him soon after, found his pulse 120, reapplied the cold applications to his head, and advised that he be kept quiet. He soon fell asleep; during the night following became restless and relapsed into a delirious condition. Previous to this, for some days, it had been noticed that he appeared to be swallowing something, and he would occasionally strangle as when trying to eat. On the 18th his mouth was found to con-

tain a good deal of pus; his pulse was feeble, and he had a dusky look about the face. The muscles of his legs and arms were completely limp and flabby, showing a great loss of tone as well as of substance. Until just previous to this time, after the paralysis of the organs of deglutition had somewhat passed away, he had taken everything offered him very readily; after pus was found in his mouth his appetite failed, and he refused to take food or drink. His mouth and tongue, which had before been moist and natural, became red, dry, and parched, sordes collected on his teeth. Pulse 100 mornings, 104 at night. On the 20th of January, pulse 104, feeble, soft, compressible; hands cold; circulation sluggish; slept nearly all the day very quietly; in the evening pulse 100 and stronger, color of face and hands good, temperature, to the touch, seemed about normal. On the 21st he remained in a deep sleep all day, from which he could be readily aroused when he was required to take food or drinks. Pulse 102. Temperature 97.8° F. 22d, A. M., pulse 108. Pus again found in his mouth and nose, and he raised fetid matter from his throat. Condition of mind clearer than on the 20th and 21st. There had been a gradual improvement and lessening of the paralysis in the organs of deglutition and muscles of the tongue. January 23d, pulse 100, temperature 97.6° F. Pulse soft, compressible, surface cold, skin mottled, restless, talkative, delirious, groans, complains of "rheumatism in the knee." 24th, passed his urine in the bed for the first time, always calling for the urinal before, took nourishment readily, asked questions correctly. 26th, A. M., got up and had a natural evacuation of the bowels, would get up and sit upon a chair for that purpose. During the night evidently had another shock, as nurse said he trembled all over. On the morning following there was paralysis of the right side, right eye commenced to weep, the head sweat profusely, was hot, temperature 102° F.; pulse 130, feeble. He complained of soreness and pain, on motion, in the right knee joint. In the afternoon complained of pain and soreness in shoulder. Pulse 149, temperature 101.8° F. Flesh hot, face flushed, rested quietly most of the day, semi-conscious. Nine P. M., pulse 140, sweating very profusely from the face only. 28th, hurts him greatly to move either legs or arms. 29th, sweating of face continues; breathing through the mouth, takes no notice of any one, knows nothing, remained in this condition until about four P. M., when he had a slight convulsion, face and head became purple; there was no movement observable after this, other than that of the organs of respiration. He died at eight P. M., forty-two days after receiving the injury.

Autopsy twenty-four hours after death, section of the head only. On removing the scalp and calvaria a line of fracture was found to extend through both tables of the skull, from a point a little in front and to the left of the centre of the calvaria down to the orbital prominence, through both orbital plates, and along the line of junction of the frontal and ethmoidal bones through the sphenoid, terminating in the sphenoidal fissure. The length of this line of fracture was about forty centimetres or ten inches. The arachnoid was found adherent to the brain over nearly the whole left hemisphere, a large clot of blood just under the point of the skull where the force of the blow was received formed a mass covering nearly half the hemisphere, another mass was seen upon the right hemisphere in the temporal region, lines of pus were found extending along

the vessels and in the sulci between the convolutions of the brain which were of a yellowish greenish color. The interior of the brain presented nothing abnormal. The convolutions were somewhat flattened and softened.

Of eighteen cases of fracture of the skull from falls, reported in the Medical and Surgical History of the War of the Rebellion, thirteen were fatal, dying of encephalitis usually from the tenth to the fourteenth day. Of those dying of abscess of the brain, the average time was three weeks, chills and other phenomena of pyæmic infection being present. Of eleven cases reported of fracture involving the base of the skull the eleven died; of these, two cases only were accompanied by the peculiar colorless discharge from the ear, said to be indicative of fissure of the petrous bone.

It was observed that fissures or long linear fractures with little depression characterized the fractures of the skull from falls or railroad accidents.

RECENT PROGRESS IN SURGERY.

BY H. H. A. BEACH, M. D.

"SPONGE GRAFTING."

SURGEONS have long recognized the difficulty in removing sponges, unprotected by a fold of cloth, from raw surfaces to which they have been applied some hours before, as compressors to check hæmorrhages. Granulations shoot into the interstices with great rapidity and their rupture is necessary before the sponge can be separated from the fresh surface.

Dr. D. J. Hamilton¹ has made a careful study of the condition of the sponge and wound under these circumstances, and, with the aid of microscopical observations, determined that the sponge becomes vascularized, as in the case of a clot, and may become the medium for the construction of new material in the healing of wounds and ulcers. The paper is one of exceptional interest and is deserving of careful consideration and verification. He concludes with the following suggestions:—

"Having once recognized the principle that a porous body may become vascularized and be the medium for the construction of new tissue, the application of the method to various purposes naturally suggests itself. In applying any porous body with a view to this organization certain points must always be kept in mind. The porosity of the body must be such that all the canals freely communicate. Sponge is exquisitely suited for the purpose on account of the free anastomosis between its channels, but many other substances might be utilized in the same way. I have of late thought that charcoal or calcined bone might be employed in certain cases. For one purpose at least such a solid framework might be useful. Where it is desired to prevent contraction of the newly formed tissue when it cicatrizes, where it is of moment to retain the newly formed tissue of its original bulk, then a solid framework must be employed. A solid framework will, I feel sure, organize just as a sponge would, and will have the special quality of preventing cicatricial shrivelling. When once incorporated with the tissue it will not cause any more irritation than the calcareous matter of a bone does. A dead body of this kind is not of itself an irritant. It is the injurious application

¹ Edinburgh Medical Journal, November, 1881.

of it, or the septic matter which it may introduce, which gives rise to the mischief.

"Such a solid framework, it strikes me, would be particularly useful for forming new bone. One of the great dangers of a simple periosteal detachment operation is that the future bone is not sufficiently bulky and strong. By supplying a solid framework of this kind we would avoid this, and the formation of bone would proceed within it just as well as in the spaces of cartilage or the meshes of a fibrous tissue. Bone is nothing more than a fibrous tissue modified by being impregnated by calcareous and other salts. The particular elements which go to form bone are nothing more than connective tissue corpuscles, and by supplying a framework of the above nature for these to ramify within, bone might be grown to an almost unlimited extent. The spongy framework, I should think, although I have not as yet had any practical experience in the matter, would be rather too yielding, and would be liable, when infiltrated with bone elements, to contract. Whether the formation of bone would commence early enough to prevent this I do not know. It is quite possible that it might.

"Wherever it is applied, it must be always remembered that the sponge or other framework must be employed merely for the purpose of filling a vacancy, otherwise it will cause great inflammation and the efforts at organization will not proceed. My experiments so far have shown me that, if thrust between two portions of a muscle, for instance, without a portion of the muscle being excised, organization does not proceed nearly so equally as when a piece of tissue is removed and the sponge merely takes its place. The reason is obvious. If thrust between the muscles of a part it will, especially when it gets softened by the juices of the tissues, tend to swell, and, by pressing on neighboring blood-vessels, will interrupt the circulation within them and so induce an inflammation. Where it merely fills a vacancy, however, the case is very different, and organization will then follow. Before being applied it should always be rendered antiseptic, and, of course, this specially holds good of its application to a fresh wound.

"Every one will admit that nothing is more conducive to putridity in a wound than a septic sponge, while, if applied in an aseptic, or rather antiseptic, condition, and dressed with the view of retaining it so, it can be kept, as shown in one of my recorded experiments, perfectly free of putrefaction through a period of several months.

"So far as I see at present the method of 'sponge-grafting' seems excellently suited for growing new tissue where that is insufficient to cover a part or to allow of stretching, but whether it may not have a wider range of application remains for future experience to demonstrate. The only objection which I perceive to its application is the somewhat long time required to organize it. During the first ten days I found that a part of a sponge placed in the abdomen had organized from an eighth to a quarter of an inch, but it always happens that one part organizes quicker than another, and hence, although in a large wound one part may thoroughly organize in, say, a month, other parts of the same sponge require longer. I cannot see, however, what objection there would be to the patient going about, if this were practicable, after the sponge had once become fixed. On the contrary, I should think that this might actually, in certain cases,

exert a beneficial influence upon the organizing powers of the tissues."

MODERN LITHOTRITY.

Dr. Bigelow's paper appeared in the *London Lancet* soon after (September 21th) his exemplification of the new operation before the International Congress. It presents the various improvements which he has devised in the construction of the instruments since his first demonstration of the leading principle of the new method, namely, the tolerance of the bladder to instruments, and its intolerance of fragments. An abstract would hardly do justice to the paper, the value of which is dependent upon details which are of the greatest service to the operator who hopes to do a successful lithotripsy.

The latest achievement of Dr. Bigelow in this direction is the removal of a calculus, weighing 1380 grains, at a single sitting of one hour and fifty-five minutes. The patient experienced immediate relief from the distressing tenesmus which had tormented him for nearly four years, and recovered without a bad symptom. The bladder was so completely emptied that at a subsequent washing, one week after, only a minute fragment was found, weighing two grains. The writer has copied from the hospital records the temperature of the patient as showing how little the system may be disturbed by this operation. Before the operation the temperature was 100° F. The operation was done on the 17th day of November; during the ten succeeding days the temperature was: (1) 102° F.; (2) 101°; (3) 99.5°; (4) 99.5; (5) 99.4°; (6) 99.2°; (7) 98.8°; (8) 99°; (9) 98.8°; (10) 98.8°.

SUPRAPUBIC LITHOTOMY.¹

Langenbuch, of Berlin, advocates this method in preference to all others in removing stone, claiming that the risk of wounding the peritonæum is not so great as is supposed, and that the antiseptic method is applicable, whereas, in perineal lithotomies it is hardly possible to carry out the details of that method vigorously, in consequence of the anus being so near the wound. Of four hundred and seventy-eight cases of suprapubic lithotomy, collected by Dr. Dulles, only thirteen were complicated by a wounded peritonæum, three of which were fatal. The author showed that a stone weighing more than two ounces could be extracted with less risk by the high than by the perineal method. The comparative advantages of perineal and suprapubic lithotomy are considered by the author, who states that urinary infiltration of connective tissue it is pointed out is a danger common to both operations, which, however, in the high operation can be prevented. The danger of this infiltration when it has occurred is much less after the high than after the perineal operation, since the epicyclic is more accessible and less confined than the periprostatic and circumrectal connective tissue, can be more readily incised and disinfected, and as it is not connected with any large venous plexus is less likely through its decomposition to set up general septic infection. In the high operation the incisions can be made carefully and precisely, and through structures that are freely exposed to view, and there is no necessity for forcible laceration and contusion of connective tissues and other soft parts. It may be said the author suggests

¹ W. Smith, *London Medical Record*. *Archiv für klin. Chir.* Band xxvi., 1881.

that it is as difficult to set up urinary infiltration after the high operation as it is to prevent such infiltration after lithotomy by the perineum.

For the removal of a large stone — one with a maximum diameter of about two inches — the safest proceeding, Lauenbuch thinks, is the high operation performed in two stages and under strict antiseptic conditions. To meet the case of a monster stone, measuring from four to seven inches in diameter, the extraction of which in the second stage of the high operation would probably cause much laceration of the recently healed superficial parts, and also of the peritoneal fold, he proposes a complicated proceeding. In the first stage, the anterior surface of the bladder is freed to some extent of its layer of peritoneum, and a plastic operation is performed on this membrane. In the second stage — that of extraction performed after an interval of from five to eight days — elaborate preparations are taken to disinfect the bladder.

INJURIES TO THE HEAD.

Dr. Macewen draws the following conclusions from the study of an interesting series of head injuries, and reports them in the *London Lancet* for October 1st.

"In head cases, where convulsions are likely to occur, it is of importance, as Dr. Robertson (Glasgow) has pointed out, to have an intelligent observer in constant attendance, as the record of the first indications of the impending convulsion and the parts affected by them is of great use as a guide to localization. At a variable time after the commencement of the attack, the convulsions, in many instances, become general, and then the indication as to the special localization are lost. Cases II. and III. illustrate this point. In both the seizure was at first limited, and pointed to the localization, and in both the convulsions afterwards became general, losing all special significance. Again, a symptomatic appearance may occur during or after a convulsion, which, if noticed and recorded, may aid the surgeon in his diagnosis. This is exemplified by the aphasic condition which came on in Case IV. after the convulsions, and which lasted only a short time. Had it escaped notice the particular part of the frontal lobe, which was the seat of the abscess, could not have been made out. A careful record of temperature is of great service in indicating the approach of convulsions.

"In each of the cases noted above, the convulsions were preceded by a rapid rise of temperature. The rectal temperature was taken every three hours, until it began to rise, when it was noted every hour, until it again descended to normal. In this way the careful record of the temperature gave those in attendance a forewarning and prepared them for what was likely to ensue. The first case mentioned shows that a portion of bone destitute of pericranium may be shifted from one part of the skull to another and remain in that position, apparently alive, and uniting with the skull, form an osseous plate over the trephine aperture.

"The first three instances illustrate the perfect immunity from inflammatory products which attend aseptic trephining. When the skull can be opened, the cerebral coverings incised, and the brain exposed without fear of inflammatory mischief, trephining ought to be employed, when the localizing of the brain pressure is established. Besides operating in traumatic cases, trephining is justifiable in idiopathic cases, such as, for instance, tumor of the dura mater."

Hospital Practice and Clinical Memoranda.

A CASE OF BURNING FROM THE EXPLOSION OF A MORTAR SHELL, FOLLOWED BY INFLAMMATION OF THE TIBIA.

SURGICAL REMINISCENCES OF THE WAR. NO. 2.

BY GEORGE HOLMES BIXBY, M. D.

TWO OPERATIONS FOR THE REMOVAL OF DISEASED BONE, AT AN INTERVAL OF A YEAR; ABSCESS OF THE HEAD OF THE TIBIA AFTER THIRTEEN YEARS OF PERFECT HEALTH; OPERATION AND RECOVERY.

C. S., an ex-soldier, consulted me for the relief of a chronic affection of the right tibia.

Eleven months before, at the siege of Petersburg, in Virginia, while sitting in the trenches, apparently out of harm's way, a mortar shell exploded in such close proximity to his person that the anterior portion of the right tibial region was subjected to an intense heat, which he compared to a scald from boiling water. On exposing the parts, the limb was found deeply discolored and apparently in a charred condition. Deep-seated inflammation and extensive sloughing of the soft parts rapidly succeeded.

After a stay of three months in the hospital the ulcer healed, with the exception of a space the size of a twenty-five cent piece, which resisted all treatment. His general health being well nigh restored, he was sent home to complete the cure. A few weeks subsequent to his return, he came under my observation. Two weeks previously, without any apparent cause, he was seized with a severe chill, and almost immediately afterward by an intolerable boring pain along the shaft of the tibia.

On inspection, signs of general oedema of the right limb, and a decided difference in the size of the two limbs, were plainly observable. An indolent ulcer occupied a space near the middle portion of the bone, which on closer inspection proved to be the opening of a sinus, leading into the cavity of the bone. A thorough exploration resulted in the removal of a number of fragments of dead bone. There was an immediate cessation of the pain, the process of repair proceeded without interruption, with a corresponding improvement in the general health, and in due time he was able to be about with the aid of crutches.

Twelve months later, when apparently in the enjoyment of fair health, there suddenly ensued a similar set of symptoms, to those of a year before, namely, severe protracted chill followed by boring pain in the tibial region. On this occasion a small ulcer occupied a point at the lower angle of the now consolidated cicatrix. As before, the sinus led to the cavity of the bone, at the fundus of which detached fragments were easily detected. A single opening with a small trephine proved to be too small to admit of their removal, and not until an opening nearly four inches long had been made was it possible to raise up the sequestrum, four inches in length, and no larger than an ordinary knitting needle.

The cavity was unsparingly freed of every vestige of suspected tissue, little regard being paid to preservation of the periosteum. Again, as before, the work of repair went on admirably, and in about three months the opening caused by the trephine and chisel had been

entirely filled up with normal tissue. In less than six months after the operation he was fully restored to health, threw away his crutches, and zealously resumed his duties as a mason.

In May, 1880, after a lapse of thirteen years, I was unexpectedly summoned to the bedside of my old patient. Until within a few weeks during this long period he had enjoyed the most perfect health. Shortly after, having been subjected to several weeks of extraordinary physical exertion, he was suddenly seized with a most violent and protracted chill, succeeded quickly by a boring, tearing pain in the head of the tibia.

I found the patient somewhat emaciated, with a dry tongue, injected conjunctivæ, but with a full, slow, unirritable pulse. Hot fomentations, opiates, locally, hypodermically, and internally applied, failed to afford permanent relief. The symptoms above referred to were at once recognized as the result of the protracted use of opium and not as typhoidal, and at once excluded as a bar to any immediate surgical interference. The history of the case, both remote and recent, the characteristic pain caused by pent-up matter, referable directly and distinctly to the head of the bone, convinced me that I had to do with an abscess of that part.

Putting him thoroughly under the effects of ether, I proceeded to explore the head of the tibia with a small-sized trephine. I had hardly reached the depth of a third of an inch when a gush of fetid pus most satisfactorily confirmed the diagnosis. The walls of the large suppurating cavity, containing at least two ounces of pus, were now carefully freed of every vestige of diseased tissue.

On recovery from the anæsthetic it was found that the enemy had been routed, for not the slightest amount of the old pain remained. The process of repair again went on as usual, and at the end of four months he was able to resume all his ordinary duties. The use of cod-liver oil during the winter months for years to come was strictly enjoined.

A CASE OF DEATH FROM EXHAUSTION FOLLOWING EXCESSIVE HÆMORRHAGE DURING LABOR.

BY W. F. BRICHIN, M. D., HARV.

Mrs. S., aged thirty-two, eight months and a half advanced in pregnancy with her sixth child, nothing unusual ever having occurred in her previous labors excepting that they were very tedious, but not sufficiently so to necessitate the use of instruments.

On the 24th of November she was "taken flowing" while in the act of putting down a carpet. This was at about two p. m.; at three I was called, found her on a lounge in severe pain, shivering, her feet and hands cold, and feeling very weak. On examination I found that the neck was not wholly obliterated, the womb dilated to the size of a silver dollar, and the patient flowing freely, the color of the flow being very dark. I could not discover anything to indicate placenta previa. I then ordered her to bed, and after a few hours, the os having dilated considerably more, I gave her a dose of fluid extract of ergot, which checked the flow so long as the effect of it continued. After waiting a few hours longer I ruptured the membranes, thinking that this might hasten labor and control the hæmorrhage. My anticipations were realized for

a while, and then it commenced again. She now began to complain of severe pains in her head, arms, and legs. I now suggested the use of forceps, which was strenuously opposed by the husband, who said she "had always got through without the aid of instruments." After explaining the case to him he consented, she at the same time saying "something must be done." At eleven p. m. I applied the forceps, and delivered her about 11.45 (without ether) of a dead child, weighing about ten pounds. I then removed the placenta, and passed my hand over the abdomen, and found the womb had a "doughy feeling." I then passed my hand into the womb, and found it filled with clots, which I removed, the womb contracting down firmly. I then gave her a dose of ergot, morphia, and whiskey, and remained with her until half past one a. m. During the first hour after delivery she threw her hands and body around almost incessantly, saying "it was impossible for her to remain quiet, she felt so weak and peculiar." When I left her, at half past one a. m., she felt quite comfortable and sleepy; the pulse was weak but steady, and the womb firmly contracted. At three a. m. she again became restless, and before I could be summoned she threw up her hands, gasped a few times, and died.

In this case I am unable to say from whence the hæmorrhage came, but in all probability it came from the fundus, as the flow was very dark at first. The administration of ergot at the time I did might be open to criticism, but in this case it did certainly control the hæmorrhage while its effects continued, and likewise there was an arrest after the rupture of the membranes.

The only thing to be regretted in the case, I think, is that the forceps were not applied as soon as the strength began to fail.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

M. H. RICHARDSON, M. D., SECRETARY.

RÖTHELN.

At the meeting of October 17, 1881, Dr. JONES read a paper on rötheln, which is published on page 607 of this number of the JOURNAL.

Dr. C. H. WILLIAMS asked how one could distinguish rötheln from a light case of scarlatina in which the symptoms may be very mild.

Dr. JONES replied that the disease would not suggest scarlatina at all. The eruption is very different, being in scarlatina diffused. In all cases of rötheln he had seen there were blank spaces unaffected by any rash.

Dr. A. T. CABOT said that he understood the reader to say that a second attack of measles is very rare. This last year during the prevailing epidemic of measles a second attack was very common. Sometimes even there were three. He thought that the second attack might assume a very light form, differing from the true measles just as varioloid differs from variola.

Dr. JONES thought that the disease presented a type entirely new and different from the ordinary measles.

Dr. BRODGETT said, with regard to the confounding German measles with scarlatina, that he could recall three cases of so-called German measles in this city which were treated as such. At the end of the fourth

day the symptoms of the disease had disappeared, but the patients did not recover. They died at the end of a certain time with symptoms of nephritis and other phenomena of scarlatina. It was therefore thought that the original disease was probably scarlet fever; Dr. Blodgett thought it easy to make a mistake in diagnosis between a light case of scarlatina and the disease called *rötheln*.

In reply to Dr. Wells, Dr. JONES said that there were three cases during one week, one after the other, in one family. In other families there was no contagion, the cases being isolated.

Dr. HAVEN thought the profession in Boston too much inclined to decide this question of a specific exanthem from their own experience alone, which in most instances consisted of only a few sporadic cases; a judgment based upon these must be imperfect, but if we take a broader view of the subject and grant, as seems but fair, the accuracy of observations in Germany — where the disease, if it exist at all, occurs in epidemics — it seems as though an affirmative answer was inevitable. Men with the experience of Gerhardt, Steiner, Vogel, and many others of less note as authorities in pediatrics, flatly affirm the dicta of contagion and immunity spoken of by the reader. In the face of this positive testimony that such a disease *does* exist, negative evidence that it has not been present in a certain few cases, or that these may have been a second attack of measles, has little bearing on the question, Is there a specific exanthem *rötheln*?

Dr. Haven thought Dr. Jones's cases differed from most reported as *rötheln*, in the absence of catarrhal symptoms; these are usually present, lighter than in measles, but well marked and developing either simultaneously with or at the most twelve hours before the eruption; this being one of the principal points of differential diagnosis, as even in the lightest cases of measles the prodromal stage is normal — three days. There have been several epidemics reported in this country of late, and also abroad, where the lung complications were very severe, a fatal result following the extension of the catarrhal trouble in the lungs.

Dr. EDGERLY remarked that cases had been very common in Cambridge which differed both from scarlatina and from measles. In these cases one thing that struck him was that the patients were not so sick as the symptoms would seem to warrant. The general characteristics of this disease were similar to those described by this reader. The child would be found one day exhibiting the eruption; the next day would be better, and on the third would be well. There was one symptom which he remarked so often that it seemed to him characteristic of the disease, and that was swelling of the glands of the neck. It was in fact always present. After his attention was called to it he used it as a distinguishing mark of the diseases, so that finally, if such swelling occurred he at once suspected the disease might be German measles, and generally found it so.

Dr. J. B. AYER agreed with Dr. Cabot, that the repetition of measles in the same patient is very common. He knew of three such cases. Last March he had seen a number of cases which were of great interest to him. Within a few days of each other twenty-one children were taken sick. Among them was one very severe case of measles. Conjunctivæ were very much inflamed. Fever was high, and the patient needed much attention. Two others were cases of measles of

a lighter type. The remaining eighteen were very mild. In twelve to forty hours the eruption had disappeared. Generally in about twenty-four. There was no treatment required. One of these patients went to Martha's Vineyard, where she had a second attack of measles. The eighteen mild cases were not like ordinary cases of roseola, measles, or scarlatina.

Dr. C. H. WILLIAMS asked whether the reader had noticed in the cases of *rötheln* any want of power in the accommodation of the eyes after convalescence.

Dr. JONES replied that in two or three of his cases there had been complaint of weakness after recovery.

Dr. WILLIAMS then stated that after an attack of ordinary measles such a condition was sometimes met with and might be very persistent, he called the attention of the members to the need of great care in the use of the eyes after and especially during an attack of measles.

In reply to Dr. Williams, Dr. HAVEN said that an ophthalmic surgeon of wide experience had stated to him, last winter, that he had been struck by the absence of any severe ocular trouble subsequent to second attacks of measles so common in this last epidemic; that although the subsequent difficulty did not seem to depend on the severity of the disease in the primary attack, it often being marked in the mildest cases, in the second attack it was altogether absent. This tended to confirm the suspicions of the speaker that many cases of second attacks of measles were in reality *rötheln*, and that there had been the two coexisting epidemics.

CANCER OF THE LIVER.

Dr. H. E. MARION reported the case.

J. L., died October 15, 1881, aged seventy-one years, four months. American; farmer. Always used alcoholic stimulants. Always enjoyed good health until within the past two years, when he began to complain of severe, burning pain in right hypochondriac region, recurring at intervals and with more or less severity. Loss of flesh has been gradual; during the past six, and particularly the past three, months, it has been very marked. No disturbance of bowels until recently; has suffered from diarrhoea. Hands and feet swollen most of the time lately; no œdema in any other part of the body. Said never to have been yellow or jaundiced, but lately family have noticed that his complexion was of a pale straw color. Never acknowledged that he was a sick man nor consented to have a physician, remarking at one time, "if he had a doctor he should not live two days" (he lived fourteen hours).

I saw him for the first time on the evening of October 14th, when I learned the foregoing history: —

On examination I found marked emaciation; extremely feeble thread-like pulse; no cardiac murmurs; hepatic dullness extending from just below right nipple to 12 cm. below ribs, and to left nearly on level with umbilicus; of an irregular nodular feel, nodules of unequal size; just below xiphoid cartilage, in median line, was a tumor as large as a hen's egg, immovable and non-fluctuating. An indistinct murmur was to be heard over this region. This tumor was first noticed about six months ago. Complaints of nothing but diarrhoea, which is very exhausting, and of which he wished to be relieved. Hands and feet swollen; mind clear. I directed that urine be saved for examination, and gave him —

Machinery accidents	5
Boiler explosions	12
Asphyxia by smoke	3
Asphyxia by food or vomitus in windpipe	3
Run over	8
Burns	4
Shooting	2
Explosion of nitro-glycerine	1
Blows on the head	2

The Executive Board desire to call the attention of the members of the Society to this clause in the second section of the By-Laws: "Every member shall forward to the Corresponding Secretary a report, as full and complete as possible, of each case which shall

receive his official attention." While many members fulfill this duty with conscientious exactness, giving to the Society reports of their work, which are models of medico-legal excellence, there are also many who are content with furnishing but a single line of detail. While reports of the latter description may possess a certain value as contributions to the statistical tables of the Society's Transactions, it is needless to add that they contribute little to the general fund of medico-legal science.

Our reports are annually increasing in value, and have already been consulted by medical gentlemen in search of material for illustration of medico-legal subjects.

During the year the work of filing and indexing the reports of cases has been completed up to the beginning of the present year, the result of the work making nine volumes, containing detailed reports of 1602 cases.

The last year being the national census year, we are enabled to present an estimate of the whole number of medical examinations throughout the commonwealth for a single year. This is based upon the returns already made by medical examiners representing a majority of the population. The value of statistics is greatly enhanced as the numbers of population are increased from which such statistics are compiled. For example, in one small town of 700 inhabitants, there were three suicides in one year; it would be far from correct, however, to infer from this fact that there had been 7600 suicides in Massachusetts in a year. It is not safe to compile statistics on a basis of 1000, or 10,000, or even 100,000 people. We may, however, form estimates from a million inhabitants with a tolerable assurance of reaching a uniform result under like conditions. Massachusetts contained in 1880 a population of 1,783,086. For the same year forty-one medical examiners rendered reports to this Society, representing districts containing a population of 1,312,031, leaving other districts containing 471,055 inhabitants from which no reports were returned. In order to present an approximate estimate which shall be as nearly correct as possible, it must be remembered that the medical examiners who have reported their annual work represent a dense population, mainly inhabiting the cities and large towns of the Commonwealth. The remainder who have not reported, with but few exceptions, represent a sparse population. In the latter districts the ratio of sudden, violent, or suspicious deaths is less than that in the cities and large towns. No inflexible rule can, however, be stated. The various items enumerated in our annual reports are affected by the comparative density of population in a somewhat different ratio. Thus, the ratio of railroad accidents and other casualties is much greater in or near the cities and large towns where railroads converge and steam-boilers, factories, mills, and dram-shops abound. On the other hand, the ratio of suicides is affected in a much smaller degree by density of population. Upon careful examination of these and of minor causes, affecting the population of different districts, we find that an addition of about twenty per cent. should be made to the total number¹ of reported views followed by autopsy, of inquests held, of fatal railroad accidents, and of other fatal accidents; and of ten per cent. to the total number of views, of deaths from natural causes, and of suicides as reported.

¹ See summary in first section of Report.

The following table represents the estimated returns from the whole State, and is probably not far from correct: ¹—

Estimated whole number of views made in all districts	1145
Estimated whole number of autopsies made in all districts	249
Estimated whole number of inquests	215
Estimated whole number of deaths from natural causes	422
Estimated whole number of railroad accidents	149
Estimated whole number of other accidents	301
Estimated whole number of suicides	138

In compliance with a vote of the Society, the Executive Board have during the past year investigated the subject of comparative expense of the coroner and the medical examiner systems in Massachusetts.

While it is impossible to present an exact statement of the expenses under the old and the new laws, the results obtained from the replies of county treasurers are favorable in the aggregate to the Medical Examiner Law of 1877.

Certain points in this investigation require explanation before presenting a tabular summary. The proceedings attendant upon an inquest are necessarily of a two-fold nature, medical and legal. Under the old law both offices were combined in one individual, the coroner first viewing the body in person, together with his jury, and then sitting in the character of a magistrate and hearing the evidence.

The bill of expense of this two-fold proceeding was also summed up in one paper, and the entire sum paid to the coroner, to be distributed by him to the various persons entitled to fees, including the jury, the witnesses, the constable, the scribe, the surgeon, the chemist, etc.

Under the present law the proceedings attendant upon an inquest are divided between the medical examiner and a district or municipal justice. Hence the bill of expenses is also naturally divided, the medical examiner rendering an account only of that portion of the work which is strictly his, and the clerk of the court or trial justice also rendering his portion of the expense upon a separate paper. This division of the expense is rendered doubly necessary by the fact, that, while under the old law an inquest usually followed quickly after the official view of the body (often within twenty-four hours, and almost invariably within a week), on the contrary, under the present law, a considerable delay is usual between the view or medical examination and the inquest, — often from one to six months elapses, — and the medical examiner's account may be sent in and settled before the inquest takes place.

Unfortunately for this investigation, while it is an easy matter to obtain an exact statement of the medical examiners' expenses, each county treasurer having kept these as a separate item, on the other hand, the court expenses of inquests (consisting mainly of constable and witness fees) are in some counties mingled with the criminal expenses of the same courts in such a manner that it is impossible to separate them. We have, however, obtained from county officers an average estimate of the cost of inquests, and this is quite uniform for those counties which have not rendered a separate and exact return of this item. The average

cost in those counties, with the exception of Suffolk, is about \$14.50 for the legal part of an inquest; in Suffolk County the average cost of inquests in the courts under the new law has been only \$7.26.

For the purpose of convenience, the expenses of two periods of three years each under the old and the new laws are shown in our report. The two half years of 1877 (the new act took effect July 1, 1877) are not considered, since the introduction of that year would render liable a confusion of accounts in some county reports.

The period from January 1, 1874, to December 31, 1876, is selected under the old law, as being the nearest available period in point of time and extent of population; under the new law, the years 1878, 1879, and 1880 are selected as being the only three complete years for which accounts have yet been rendered.

The following table is necessarily somewhat incomplete. It shows the comparative expenses of the two periods selected as fully as possible from the replies received from all counties. The result is favorable to the medical examiner law of 1877, for the reasons which will be stated: —

Counties.	Population, 1880.	Amount paid for Coroner's Inquests and Views in 1874, '75, and '76.	Paid for Medical Examiner's Fees in 1878, '79, and '80.	Paid for Inquests in the Courts in 1878, '79, and '80.
Barnstable .	31,945	\$912.38	\$311.20	\$178.84
Berkshire .	69,049	1,384.00	675.23	297.25
Bristol . .	139,121	3,108.47	1,887.49	—
Dukes . .	4,305	246.26	131.80	—
Essex . .	244,640	6,263.86	3,457.94 ²	—
Franklin .	36,000	496.00	826.68	—
Hampden .	104,117	3,041.47	3,111.13	—
Hampshire .	47,235	1,772.79	790.60	—
Middlesex .	317,951	7,002.10	5,212.99	—
Nantucket .	8,726	32.90	52.21	—
Norfolk . .	964,62	2,108.85	2,698.09	—
Plymouth .	74,024	894.20	551.70	169.55
Suffolk . .	387,626	28,828.63	20,276.26	1,620.26
Worcester .	226,885	4,878.42	1,451.45	1,224.97
State ³ . .	—	2,741.71	5,741.17	—
Total . .	1,783,086	\$63,712.04	\$17,175.94	\$3,490.87

The figures given in the first three columns of the foregoing table are matters of record, as are also those in the last column, so far as presented. In the case of those counties from which no answers could be obtained to complete the record in the fourth column an estimate is given, based upon the reported work of medical examiners for the past three years, combined with the replies of county treasurers. It cannot be far from the truth. These estimated inquests number 265, and their aggregate cost, at \$14.50 each (the average, as mentioned above, for counties other than Suffolk), was \$3842.50. Adding this sum to the totals of the last two columns in the table, we have a grand total of \$51,509.31 as the whole expense of inquests and medical examinations in Massachusetts, during the three years 1878, 1879, and 1880. This sum is much less than the total expense for similar service under the coroner laws during the three years 1874, 1875, and

² Costs of inquests in the courts are included in this sum, but not separately reported.

³ These amounts were paid from the State Treasury for inquests, medical examinations, etc., on the bodies of strangers having no known legal settlement in this Commonwealth.

¹ See report of two columns in this estimate; reference is made to the report of the Massachusetts Reg. Stat. in Report (1880), pages 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

1876, the difference in favor of the Medical Examiner Statute being \$9202.73.

A favorable point to be noted in the foregoing tabular summary, is the difference in population of the two periods selected for comparison. Between the middle years of each period of three years (1875 and 1879) the State had gained over 100,000 inhabitants.¹ Had the population remained the same, the difference in absolute expense would have been considerably greater than is shown by the table.

The chief reason for the diminution in expense, appears to be the abolition of the coroner's jury. Under the old law, a jury of six men was requisite for every inquest, their fees being \$1.25 each per day, and mileage. An inquest often continued for several days; a single day's pay for a jury was \$8.22, but since an inquest often continued two or more days, the average pay of a coroner's jury may be safely stated as high as \$12.

As an illustration of this change in consequence of the abolition of the jury, we are permitted to give the following abstract of a statement, submitted by a medical examiner, who was also a coroner, and has kept an accurate account of all expenses under each régime.

Amount paid by county treasurer in all cases occurring in a district containing about 9500 people in 1874, 1875, and 1876, \$296.57; of this sum, \$86.10 was paid for jurors' fees.

Amount paid by county treasurer in same district for all cases, in 1878, 1879, and 1880 (population about 10,000), \$238.75.

The amount of medico-legal work done in the latter period was somewhat greater than in the former.

Another reason for a lessening of expense is found in the diminution in the number of inquests, if we may judge from the returns of the only counties which have given a definite statement upon this point. In the counties of Plymouth, Norfolk, and Essex, in 1874, 1875, and 1876 there were 124 inquests. In 1878, 1879, and 1880 there were only 75 inquests in the same counties. The same general fact is true of other counties, although definite figures are not given. It would be safe, however, to estimate the decrease in the number of inquests, throughout the State, as at least 33 per cent, since the passage of the new law. The reasons for this change may be discovered in the appointment, to fill the offices formerly held by coroners, of men whose education necessarily fits them for the work which they are expected to perform. Under the old law, a man found dead, even without the least suspicion of violence, as in a simple case of heart disease, or apoplexy, would in all probability be reported to the village coroner, provided the most common hypostatic marks of post-mortem discoloration were noticed by some bystander, such marks being often interpreted by the popular mind as significant of a violent death. Hence the coroner sets in motion the cumbrous machinery of his office. In the first place he sends for a constable. The constable summons a jury. The witnesses come next, and last of all the nearest physician is summoned, whose evidence satisfies the assembly that the man died a natural death.

Under the working of the present law, the order of procedure is reversed. The medical officer first views the body, and in a case like that just referred to, simply reports it as a view, with a charge of \$4.00 and mile-

age. If, however, he believes there is a reasonable suspicion of violence, as revealed by the evidence shown him from an external examination of the body, and upon personal inquiry of the necessary witnesses, and also by an autopsy if that be found requisite, the case is reported to the proper authorities for inquest.

Under the old law, so far as can be learned, the proportion of inquests to cases of all sorts (views and inquests) was at least as high as 40 per cent.

Under the statute of 1877, the proportion of inquests to views of all sorts has been not more than 22 per cent.

The number of autopsies in proportion to the population, has been somewhat increased since the abolition of the old statute, but by no means sufficiently to counterbalance the diminution in expense caused by the abolition of the jury. A reason for this increase is also found in the appointment of officers who have an intelligent appreciation of the prerequisites to a medical examination in cases of violent or suspicious death. Cases have occurred in this Commonwealth in former years, and occasionally occur in neighboring States, in which criminals go unpunished through the neglect of a coroner to order a thorough examination, before the usual post-mortem changes interfere with a correct interpretation of the lesions present at the time of death.

The tests to which the Medical Examiner Law of Massachusetts has been subjected during the past four years of its operation have thus far shown it to be less expensive, less liable to the perpetration of fraud, and more efficient than the Coroner Laws which it has superseded. We trust that its successful operation in Massachusetts will soon lead to its introduction throughout other States of the Union.

PROCEEDINGS OF THE MONTHLY PHARMACEUTICAL MEETING OF THE MASSACHUSETTS COLLEGE OF PHARMACY.

B. F. DAVENPORT, M. D., REGISTRAR.

AT the regular meeting of December 13, 1881, DR. DAVENPORT spoke of the zealous labor of Charles Rice, Ph. D., chairman of the committee on the revision and publication of the United States Pharmacopœia, and of such points in regard to the new revision as had already been settled by the action of the convention which met at Washington in May, 1880, and also by the committee of revision since then.

PROF. G. F. H. MARKOE spoke on several matters of detail in the work of the revision.

MR. W. W. BARTLET thought that it was unfortunate that the convention had voted to omit all mention of doses from the Pharmacopœia, as apothecaries are thus left without an official standard for judging of the doses safe to be dispensed.

PROF. J. F. BARCOCK argued that pharmacists acted against their own self-interests in allowing the public to consider them as assuming any responsibility for the correctness of the doses given in the physicians' recipes which they dispensed. They should allow that to rest entirely with the physician, where it truly belonged, the pharmacist's responsibility ending with ascertaining the true intent of the prescriber, and then in dispensing in strict conformity thereto.

DR. F. H. WILLIAMS thought that a pharmacist

¹ State census of 1875, 1,651,652. National census of 1880, 1,783,086.

should vary in no particular from dispensing all recipes just as they were written, but that in all cases where there was any doubt as to what was the real intent of the prescriber, he should spare neither time nor trouble in removing the doubt by a personal communication with the physician before dispensing.

Dr. EDW. M. BUCKINGHAM said that these cases of doubt could be very much decreased in number if there was some agreed upon conventional sign to be always used by physicians when they wrote for any unusual dose, which would signify to the apothecary that it was an unusually large dose that was really intended. This is the use of the exclamation point in the German Pharmacopœia.

Mr. H. W. LINCOLN offered the objection to this simple sign that physicians would acquire the habit of attaching it to all of their recipes, which would be the same as saying "my recipes are always correct." Moreover, this is such a simple sign as to be very liable to be carelessly made, and thus may be overlooked, or, on the other hand, thought to have been intended to be made when really it was not.

For this difficulty Dr. DAVENPORT proposed the use of the word sign (*sic*), as being something already in conventional use with the desired-for significance. This being a word, yet a very short one, and, moreover, being inclosed as a parenthesis, could not very well be mistaken for anything else.

Dr. F. H. BROWN thought that one of the best safeguards for the physician against errors in prescription writing was for him to use recipe blanks bound with stubs, as in bank-check books. Here, in copying the recipe upon the stub for preservation, any error in the writing would probably be discovered.

Mr. S. A. D. SHEPARD thought that the custom of the one who had put up the recipe repeating it from memory to another who at the same time was reading the recipe itself, was the best safeguard on the part of the pharmacist against any error in dispensing, for that the one repeating from memory would certainly say what he had actually done rather than what he ought to have done. A more general, thorough professional education of all apothecaries, after having received the advantages of a high school education, was what the great recent progress in pharmaceutical science imperatively demanded. This was the sphere of action which the Massachusetts College of Pharmacy was now so creditably filling, and he expressed a strong desire that all physicians should fully appreciate this fact, and do their best to aid therein.

It is very much for the professional interest of pharmacists to be able to discern of, and be held responsible for, the quality of all the drugs dispensed by them, while it is very undesirable to assume any responsibility in regard to the doses prescribed by the physician.

The other already settled points in the new revision, such as the exclusive use of parts by weight in the formulae, the use of metrical weights and measures, etc., were severally discussed, and most generally approved of by all.

The College extends its most cordial invitation to all interested in pharmacy or its collateral pursuits to be present at, and to take an active part in, these meetings, which are held on the evenings of the second Friday of each month, at the College Hall, No. 1151 Washington Street, Boston.

Recent Literature.

A Treatise on the Diseases of Infancy and Childhood. By J. LEWIS SMITH, M. D. Philadelphia: Henry C. Lea's Son & Co. 1881.

We take pleasure in noticing the fifth edition of Professor Smith's Treatise on the Diseases of Infancy and Childhood.

A valuable chapter on Artificial Feeding has been incorporated in the text, and new articles on Constipation and on Strumous Ophthalmia. The chapter on Rachitis has been increased, especially that portion devoted to the ætiology of the disease. The entire article on pleuritis has been rewritten, and the anatomical characters of the disease and its treatment carefully revised.

The binding of the book is in excellent taste, and there are over one hundred additional pages in the work.

A CASE OF INJURY TO THE SKULL.

[In connection with the case of fracture of the skull, published to-day, we insert a letter clipped from the *Lancet* detailing a case exceedingly interesting in this connection, with the editor's comments thereon.]

"A gentleman, four years ago, proceeding at a rapid pace, tripped and fell heavily from the top to the bottom of a flight of stone steps, receiving a deep wound over the left external angular process of the frontal bone. He was picked up unconscious, and remained in a semi-conscious state for four days, when he was able to be removed to his home from the hospital to which he was at first conveyed. On his return home he again lapsed into a semi-conscious state, but again recovered gradually. At this time he was informed that there had been no fracture of the skull. However, since the accident he has been completely deaf on the right side, and there is a constant dropping of a perfectly clear, watery fluid from the left nasal cavity, twenty to thirty drops falling in the minute, and this without any cessation. If he hold himself with the head well thrown back the flow is diminished, as when in bed, and *vice versa*, a stooping posture increases it. There is no increased lachrymal secretion, I may mention, observable, and the patient himself says that the flow appears to him to come "from the inner side and behind the eye." Local astringents have been tried without any effect. Besides the extreme discomfort it occasions, it prevents him from following his profession almost entirely. If any of your readers could inform me of or suggest any remedy likely to prove of benefit they would much oblige."

This case presents features of great interest; the fluid discharge is either cerebro-spinal fluid draining through a fracture in the cribriform plate of the ethmoid bone, in which case it will be found to contain a minute trace of sugar, or it is a watery fluid excreted from the lining of the nose or one of its adjoining cavities. Such a case was described by Sir James Paget in the *Clinical Society's Transactions*, where after death a polypus was found in the antrum. This specimen is now in the Hunterian Museum. We trust "Surgeon" will have some of the fluid collected and analyzed, and report the result. The deafness evidently indicates some serious nerve lesion. — Ed. L.

Medical and Surgical Journal.

THURSDAY, DECEMBER 29, 1881.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, Boston. Price, 15 cents a number: \$5.00 a year, including postage.

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies likewise for sale, by the undersigned, to whom remittances by mail should be sent by money order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,

No. 4 PARK STREET, BOSTON, MASS.

ANNUS MEDICUS.

It has been for many years the custom of the JOURNAL to review at the close of the year the doings of the medical world for the preceding twelve months. 1881 has not been marked by any startling discoveries, though scientists have been busy, and many matters have been discussed which promise progress for the future, and lines of study previously entered upon have been diligently followed.

Perhaps the most striking and important event of the medical year is Pasteur's further contribution towards the solution of the problem of the existence of specific organized causes of diseases, in the publication of his discovery of the virus of (*charbon*) splenic fever. Advancing in the line of work which he so successfully opened last year by the separation of the micro-organisms of chicken cholera, by the production of a modified virus culture protecting through inoculation against the original poison, he has succeeded in discovering the conditions of life of the micro-organisms constituting the poison of splenic fever, in directing their development according to a prearranged plan in such a way as to reduce their activity to any desired degree; in short, in making with certainty, at pleasure, of a deadly organism one which is benign, and which will by inoculation confer immunity against the effects of the other. These pretensions are now supported by a large number of confirmatory experiments performed by a variety of competent investigators. These recent investigations of Pasteur form a contribution at once to scientific and preventive medicine of great immediate and of incalculable prospective value and application. It is a difficult but pleasing task to direct the imagination to the position of a future generation when these initiatory labors shall have been carried forward to what even now seems must be their inevitable conclusions. No more pregnant communication was submitted to the International Medical Congress than that of Pasteur on Vaccination in Relation to Chicken Cholera and Splenic Fever.

The action of anæsthetics has been carefully studied and reported upon by a committee of the British Medical Society.

The nature of the diphtheritic contagium has undergone special study at the hands of Drs. H. C. Wood and Formad. The complete results obtained have not yet been published, but Dr. Wood has stated that the membranes produced in the trachea of rabbits, either by pieces of diphtheritic deposit or by irritants

of sufficient strength, were identical both with each other and with the original membrane, grossly and microscopically, that is, there was nothing specific in it; that the micrococci are the poison itself or the carriers or producers of it; that the power of rapid growth was not specific of diphtheritic micrococci, nor is there any specific distinction between these and those usually found along the digestive tract; that conditions outside the body favor the development of inert into active and virulent micrococci which are then capable of generating the disease in a tender throat.

The most widely interesting event of the year has been, perhaps, the assembling of the International Medical Congress in London, where distinguished honors were bestowed upon our countryman, Dr. Billings, and where one of the most interesting demonstrations was that of Professor Bigelow of his advance in the treatment of stone in the bladder, an advance which most sensibly modifies the methods of the severest of his critics.

A subject which was widely discussed at the Congress and elsewhere during the year has been the question of the propriety of vivisection, which has given rise to a large number of most excited addresses and journal articles.

In operative surgery extirpation of the stomach, as performed by Billroth, has not been followed by such success as was originally anticipated, the majority of the cases terminating fatally in a short time; they are not without results, however, so far as their influence upon surgery in general is concerned.

The use of antiseptics still continues almost as vigorous as ever, although there is an increasing tendency to dispense with many of the details formerly deemed most essential, and to rely for the success of the operation more upon drainage and cleanliness. Both in Germany and England many of the best operators have discarded the spray, claiming better results than when it was employed. The classic carbolic acid has lost some devotees, notably in Germany, where just at the present time iodoform is having an extended trial, used in the same manner as carbolic acid in gauze and dressings, and also in the treatment of cold abscesses and large suppurating surfaces. The frequency of carbolic poisoning has, with some operators, been a sufficient reason for abandoning it entirely as an antiseptic.

Death has been no less busy than usual, and his arrows have struck many a shining mark.

NECROLOGY.**AMERICA.**

George Alexander Otis, died in Washington, February 23d. At the opening of the late war he was in practice in Springfield, Mass., he joined the volunteer service and for meritorious conduct was soon appointed surgeon with the rank of major. In 1864 he was appointed chief of the surgical division of the Army Medical Museum, and bringing to his work interest in surgery and personal devotion he has pro-

duced in the surgical volumes of the History of the War, the most complete and valuable records of their kind.

Isaac Ray, died at Philadelphia March 31st. The first few years of his medical life were spent in private practice, but very soon he assumed the position of superintendent of the Maine State Hospital for the Insane, and it is in connection with this branch of medicine that his name is best known. The Butler Hospital at Providence was built under his personal supervision, and for twenty-one years he was superintendent, resigning in 1867 on account of his health. His work on Medical Jurisprudence in Insanity, published in 1838, is quoted as an authority to-day. Mental Hygiene, published in 1863, is a more popular book. Besides these he furnished many articles for journals, and his reports, while superintendent, are of very great value.

Richard O. Cowling, died at Louisville, Ky., April 2d. He was founder and editor of the *Louisville Medical News*, surgeon-general of the Kentucky State Militia, and professor of surgery in the University of Louisville.

H. Lenox Hodge, died at Philadelphia June 10th. Demonstrator of anatomy at the University of Pennsylvania, and surgeon to several hospitals, he was known rather as a successful practitioner than as an author.

Max Herzog, died in New York April 5th. He was founder of the German Hospital in New York, and one of the visiting physicians to the Mount Sinai Hospital.

Greenville Dowell, died at Galveston, Texas, June 9th. He was professor of surgery in Galveston Medical College and editor of the *Texas Medical Journal*, also the author of treatises on Yellow Fever and Malaria, and of various journal articles.

E. M. Wright, died at Chattanooga, Tenn., January 6th. He had been a member of the State Board of Health, and formerly one of the inspectors of the National Board. Was the Republican candidate for governor of his State in 1878.

George Ford, died January 7th. For over thirty years connected with the State Emigrant Refuge Hospital on Ward Island.

Dr. James P. White, of Buffalo, N. Y., died September 28th, aged seventy-one. He was President of the Medical Department of the University of Buffalo, of which he was one of the founders, and was the first professor to give clinical lectures on midwifery in this country.

Dr. Joel Pomeroy, died September 15th, aged fifty-six, of disease contracted during the war. He was the surgeon of General Garfield's regiment.

Dr. J. Gaspard Ribaud, died October 19th. Was professor of anatomy in the Montreal School of Medicine and Surgery.

Allston W. Whitney, of West Newton, died November 11th. At the opening of the war he entered the service of the United States as surgeon of the Thirtieth Massachusetts Regiment. He was a prisoner in Libby Prison for six months, and while there was

sentenced, with several other officers, to be shot in retaliation for several rebels executed by the Federals.

ENGLAND.

Andrew Wood, M. D., etc., Edinburgh, died January 25th. Distinguished especially as a consultant, his contributions to medical literature were very few, the best known being a report of experiments upon the prophylactic action of belladonna in scarlet fever. He was connected with many hospitals and a prominent figure in the Oxford Council.

William Rutherford Sanders, M. D., etc., died at Edinburgh, February 18th. Professor of Pathology and Clinical Medicine in the University of Edinburgh, he enjoyed a wide reputation as a lecturer and clinical teacher, but produced very little written work. In his consulting practice he had scarcely an equal.

George Rolleston, M. D., died June 16th. Li-acre Professor of Physiology at Oxford since 1860, he was one of the foremost figures among professors of biological science, and contributed to the literature of that subject *Forms of Animal Life*, a book of wide repute. At the last meeting of the Massachusetts Medical Society he was elected an honorary member.

I. B. Davis, one of the widest known of British cultivators of physical anthropology. His *Crania Britannica*, published in 1865, is unique of its kind. The vast collection of skulls in the Museum of Physicians and Surgeons at London were donated by him.

Mr. James Lake, F. R. C. S., died on August 14th, aged 82. He was consulting surgeon to the London Hospital.

Alfred H. McClintock, M. D., LL.D., F. R. C. S. I., aged 60, died October 21st. A distinguished obstetric physician, ex-Master of the Rotunda Lying-in Hospital, ex-President of the Royal College of Surgeons of Ireland and of the Pathological Society of Dublin.

Dr. Thomas Hayden, of Dublin, died October 30th. Author of the well-known work on *The Diseases of the Heart and Aorta*.

Dr. David Foulis of Glasgow, died October 24th, of diphtheria which followed two operations done on the same day. He was rapidly rising to eminence as a consultant in throat diseases. His removal of the larynx in 1878 attracted great attention.

FRANCE.

Maximilien Paul Émile Littré, died at Paris June 2d, in his 81st year. Only the first few years of his medical life were spent in practice, his taste inclining rather to the literary than to the practical side of medicine. He was the author of many journal articles of merit. His most extensive work and the best known of his medical productions is the complete edition of *Hippocrates' Works*, with copious notes. His dictionary of the French language is the greatest of his literary achievements, and has, in giving him so much fame as a lexicographer and philologist, obscured his merits as a medical writer. He secured a seat in the Academy after a long controversy with Bishop Dupanloup.

Maurice Reynaud, died at Paris January 29th. Especially known as a historical and medical writer. His thesis on *Les Médecins au Temps de Molière* has passed through many editions. He was a valuable contributor to the *Dictionnaire de Médecine* and to various journals, a member of the Academy, and chosen to deliver the French address at the International Congress.

Gustave Chantreuil, died at Paris June 30th. Although a very young man he was the possessor of a large obstetric practice and an associate of Tarnier in the production of a new treatise on Obstetrics. He was the translator of the works of Simpson, and author of many minor articles on gynecology and obstetrics.

Professor Jean Bouillaud, aged 86, died October 29th. The first to give positive proof of the connection between cardiac disease and rheumatism. Professor of Clinical Medicine at La Charité for a long series of years, and unsurpassed as a clinical teacher.

GERMANY.

Joseph Skoda, died at Vienna June 13th, in his 77th year. Almost the last of those distinguished men who made Vienna famous in medicine. Early in his career an assistant of Rokitansky, he later devoted himself to the study of auscultation, in 1833 being appointed second physician to the Allgemeines Krankenhaus in Vienna. In 1835 he began his practical courses of study, and in 1846 was appointed Professor of Clinical Medicine, holding the position until eight years ago, when ill health compelled him to resign. He was a teacher rather than a writer, having published nothing but short articles since 1839, when his *Abhandlung Über Percussion und Auscultation* was written; a work of exceedingly great merit and the foundation of many of our theories of to-day. Few men have accomplished as much for the advancement of medicine by their personal efforts as Skoda. He was the patron of Hebra and induced him to make a specialty of dermatology. He determined the abandonment of Latin as the language of medical lectures at Vienna in 1848. His merits were no less recognized by his countrymen than by foreigners, a gold medal being struck to commemorate his seventieth birthday.

Richard Herschl, died May 26th at the age of 56. At first the assistant of Rokitansky, he subsequently filled the chair of Professor of Anatomy and Pathology at Olmütz and Cracow, being called to Vienna in 1875 as the successor of Rokitansky. In 1855 he published a *Compendium of Pathological Anatomy*, but since then has written only for journals.

Ludwig Waldenberg, died at Berlin April 14th. He was editor of the *Berliner Wochenschrift* and Professor Extraordinary of Medicine at the Berlin University. He contributed several works on the respiratory and circulatory system.

Max Perls, died at Giessen May 15th. Professor of Pathological Anatomy and Director of the University of Giessen, he was the author in 1879 of an *Allgemeine Pathologie*.

Dr. Wilhelm Busch, aged 55, Professor of Surgery in the University of Bonn.

Dr. Otto Spiegelberg, Professor of Midwifery and Director of the Obstetric Clinic in the University of Breslau, died August 10th, aged 52. In 1858 he published his first work, *A Compendium of Midwifery*. He was, in conjunction with Dr. Credé of Leipsic, editor of the *Archiv für Gynécologie*, and about five years ago he published a large Text-book of Midwifery.

MEMBERS OF MASSACHUSETTS MEDICAL SOCIETY.

Ebenezer Alden, died at Randolph in his ninety-third year. The oldest member of the Massachusetts Medical Society, his whole life was passed in practice in his native town. Outside of his medical duties he was well known from his interest in various educational institutions and the honorable position he filled on their boards of government. He was a prominent member also of the Massachusetts Historical Society. His ancestors on both sides were lineal descendants of John Alden.

Jeremiah Spofford. The senior member of the Essex North District Medical Society. He passed sixty-seven years in active practice in Groveland, Mass.

Amasa D. Bacon, of Sharon, March 29th, seventy-four.

John Bacon, of Boston, November 28th.

Arthur Clifford, of New Bedford, March 11th, twenty-eight.

C. T. Collins, of Great Barrington, April 10th, sixty.

Geo. Cahill, of Salem, January 27th.

John B. Chace, of Taunton, August, sixty-five.

Thos. B. Curtis, of Boston, December 11th, thirty-nine.

Henry Ferre, of Dalton, July 31st, seventy-nine.

Caleb C. Field, of Leominster, May 5th, seventy-three.

Geo. W. Garland, of Lawrence, May 5th, sixty-eight.

Jas. Hyndman, of Boston, May 6th, sixty-two.

Daniel Harwood, of Dorchester, October 2d, eighty.

W. H. Kimball, of Andover, September 30th, sixty-one.

E. G. Kelley, of Newquay, Eng., September 13th, sixty-eight.

D. H. Lovejoy, of Boston, February 28th, forty-two.

J. L. Lothrop, of Somerville, April 1, sixty-seven.

Wm. Mason, of Charlestown, March 18th, seventy-five.

Thos. Meekins, of Williamsburg, August 5th, eighty-four.

Erasmus D. Miller, of Dorchester, July 5th, sixty-seven.

Michael McCarthy, of East Boston, October 30th, thirty-eight.

Geo. A. Otis, of Washington, February 23d, fifty.

Daniel Perley, of Lynn, February, seventy-six.

Dana B. Putnam, of Boston, February 11th, fifty-five.

Wm. S. Pattee, of Quincy, September 18th, fifty-seven.

Edward Reynolds, of Boston, December 25th, eighty-eight.

Henry M. Saville, of New York, January 11th, forty-seven.

Joshua Tucker, of Boston, November 7th, eighty-one.

Allston W. Whitney, of West Newton, November 11th, fifty-two.

MEDICAL NOTES.

— In the death of Dr. Edward Reynolds, which occurred a few days since at the ripe age of eighty-eight years, the Massachusetts Medical Society loses one of its oldest members, and almost the last remaining link between the profession of Boston to-day and of the early part of this century is severed. The next JOURNAL will contain some account of Dr. Reynolds' life.

— The daily papers announce the death of Dr. I. I. Hayes, famous for his Arctic journeys, on the first of which he accompanied Dr. Kane as Surgeon of the expedition.

— The total number of lunatics in the county and borough asylums in England and Wales on the 1st of January last, as we observe in the *British Medical Journal*, was 41,335, consisting of 230 males and 309 females of the private class, and 18,427 males and 22,389 females who were paupers. The aggregate recoveries, as compared with the total admissions (deducting transfers), were in the proportion of 37.7 per cent. for males and 43.8 per cent. females, or 40.8 per cent. for both sexes. The mortality for the year, calculated on the average daily numbers resident, was 9.50 for both sexes. It is worthy of notice that so low a death-rate has not been shown since 1859. There were 4,198 deaths amongst the 50,175 inmates of all descriptions of lunatic asylums, twenty of which were caused by suicide. Post-mortem examinations were in 1,656 only of these deaths, which shows a falling off much to be regretted.

— Horse flesh is said to be largely used in the manufacture of German sausages.

CHICAGO.

— Within a few weeks two patients have died in Chicago from the effects of chloroform administered for the purpose of having teeth extracted. The last case occurred December 20th. The patient was in a dentist's chair, and a physician administered the anæsthetic. Thirty minutes were required to anæsthetize the patient, and from an ounce and a half to two ounces of chloroform were administered. The patient became cyanosed and ceased to breathe after two or three teeth had been extracted. He was a man about forty years old, and was supposed to be healthy, although neither the dentist nor physician had ever seen him before or even knew his name or residence. The patient was in a sitting posture during the anæsthesia and operation.

— A suit has recently been commenced against the Commissioner of Health for damages resulting from his failure to remove a small-pox patient to the pest-house. The patient lived over a store, and his re-

maining, it is alleged, caused serious damage to the business of the merchant, who now asks the commissioner to pay the amount of the injury. The suit is being watched with interest by the public and profession alike. Whether damages are assessed against Dr. DeWolfe or not, there is no doubt that in this particular case as well as many others he has failed or neglected to execute the law. The law is mandatory; it says the Commissioner of Health *shall* cause every case of small-pox, etc., to be removed to the hospital. It leaves him no discretion whatever. But in behalf of the Health Department it may be said that this law, which was passed only a few years ago, has always been exceedingly unpopular with the people *except* when their near neighbors have been stricken with variola—then they are unable to see any injustice in dragging a man from his own house whether he likes it or not, and taking him to the pest-house. Under all other circumstances the law has been loudly denounced. So, in making removals under the law, the department has always met more or less opposition; but by the good sense and discretion of the medical inspectors and health officers as well, such removals have generally been made without open resistance and often with the free consent and desire of the patients. Thus, the present epidemic finds the city with a pest-house too small. A small addition is now being made to the building which, it is hoped, will enable all patients to be accommodated who cannot be kept at their homes. In several weeks, if not months past, it has been physically impossible for the law to have been executed. Most people who have taken the time to look into the matter believe that the Health Department has managed this whole business very well indeed.

Miscellany.

LETTER FROM LEIPZIG.

MR. EDITOR.— I have thought that a short account of what one can see at the clinics and lectures here in Leipzig might not be uninteresting.

The surgical clinic is unusually good. The hospital being arranged in pavilions, the patients can be carried into the class-room without removing them from their beds; in this way all can see, and the confusion resulting from a clinic in the ward is avoided. The patients thus brought before the class are discussed by Professor Thiersch and the student to whom the case is assigned. If it is a case for operation, the operation is performed after the discussion, and all its various stages described. At one of these exercises, Professor Thiersch removed a uterus—malignant disease—by Schröder's method, of Berlin; beyond a slight attack of peritonitis, the recovery was uninterrupted. A few days later he removed a uterus—fibro-myoma—by abdominal incision, all the customary antiseptic precautions being observed. The case was not a favorable one. The tumor removed weighed fifteen pounds, and the entire structure of the uterus was involved in its growth. The patient died on the second day after the operation. I have also seen Professor Thiersch operate for stone according to Dr. Bigelow's method; the evacuating catheter used was not as large as is recom-

mended. The results were favorable in both the cases I saw. Iodoform is used very extensively as a dressing in all the minor operations. Chloroform is the only anæsthetic used.

Professor Wagner's clinic is very interesting and instructive. He usually devotes each day to a special class of cases, demonstrating diseases of the chest one day, on another day abdominal diseases, on another diseases of the nervous system, the more simple cases being shown during the first part of the semester. Typhoid fever has been demonstrated in all its stages, and I have seen two cases of "laryngeal phthisis." This exercise is conducted in the same manner as the surgical clinic, and usually five or six cases are discussed every morning, in regard to both diagnosis and treatment.

All the autopsies are held in the presence of the students, and in this way one can examine the viscera of the fatal cases which he has seen treated at the hospital. These pathological specimens are demonstrated in detail by Professor Cohnheim.

The opportunities for studying anatomy here are unsurpassed. The lectures by Professor His are beautifully illustrated by drawings on the blackboard, and by preparations, most of which are passed round the class during the exercise, which is held in the afternoon. As it is often dark before the lecture is finished one would find it very difficult to see the demonstrations on the subject, were it not for an electric light which is used to obviate this difficulty. It is carefully shaded, and a very strong light is thrown on the demonstrator's table.

There are at the present time between one hundred and fifty and one hundred and seventy-five men at work in the dissecting-rooms, and one can infer from this that there is no scarcity of anatomical material in Leipzig. The rooms are light and well ventilated, and Professor His and his assistant devote every morning to the dissecting-room. Each dissector has an opportunity of obtaining a long gown from the janitor, in which he can dissect; he also has a box assigned him, and can have his knives sharpened every evening, for a nominal sum, for the whole semester.

I have endeavored to speak of some of the advantages that are offered here. I think if it were more widely known what good courses there are in Leipzig more men who go abroad to finish their studies would come here. The expenses of living are about one-half of those at Vienna, and the courses are correspondingly cheap.

W. D. H.

LEIPZIG, November 11, 1881.

NATIONAL MEDICAL EXAMINATIONS.

MR. EDITOR.—In your issue of November 3, 1881, appears "A Plea for United States Medical Examinations." The writer very properly states that the plan has been most earnestly advocated before now. Conscientious medical men throughout our country have written and talked about the matter for the last twenty-five years, though unfortunately their ideas have never taken a tangible form.

National medical boards of examiners, consisting of army, navy, and marine hospital surgeons, under the supervision of the National Board of Health, and convened at its discretion in different parts of the country. I think would better insure competent advisers to the people than the plan of your correspondent.

The rigid examinations required for entering either the army, navy, or marine hospital services is a sufficient guarantee that a board drawn from these branches of the public service is fully able to determine the qualifications of a candidate without exterior aid or suggestion.

Congress should be petitioned to empower the Surgeons-general of the aforesaid services to place as many medical officers under orders of the National Board of Health as it may require to organize examining boards in different sections of the Union.

Considering the host of illegitimate dabblers in medicine, it would be best to make these examinations compulsory, and a candidate, upon passing a successful ordeal, should be given a certificate by the examining board, countersigned by the National Board of Health. Of course, such coercive measures would necessitate special legislation, uniform throughout the land, but the discouraging experiences of the past show us that such legislative action will not be easy to obtain.

Medical officers of the Army, Navy, and Marine Hospital service being already in government employ, no special appropriation for their pay would be needed, and Congress would only be called on for a few thousand dollars yearly to defray traveling and sitting expenses of the various boards. HESPERUS.

MEDICAL EXAMINATION IN THE UNITED STATES.

A VERY suggestive paper by W. B. Platt, M. D. Harvard and M. R. C. S. Eng., Baltimore, appears in the Boston Medical and Surgical Journal for November 3d. The multiplicity of medical boards in the States, and the cheap and easy system of medical qualification, are a grief to all respectable medical men. Every State is a law to itself in this great public matter, and the highest medical titles convey little guarantee of adequate education or examination. Dr. Platt suggests that Congress should lay aside fifty thousand dollars per year to institute a United States Examination in the capital of each State, independent of the teachers in each school, the board to consist of ten army and marine hospital surgeons. We are entirely at one with Dr. Platt, as all who wish to see international rivalry and recognition in medical education must be, in wishing to see the establishment of independent and efficient examining boards, in the United States, and an abolition of the scandal of fifty or sixty local boards. We are not quite clear that army and navy surgeons would have the necessary knowledge of detail to make good examiners. This is, however, a question of detail. Dr. Platt makes a great suggestion, which deserves embodiment in Congressional legislation. — *Lancet*.

ONE RESULT OF THE CONGRESS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I imagined that the result of the late International Congress of doctors would have been the unquestioned acceptance by foreigners of British habits and customs, but I regret to say I am disappointed. When I was at Krankenbad the other day, I was astounded by the outrageous ignorance still displayed by German medical men of some eminence. I was dis-

quissing with Herr Krauts, the celebrated physician, the difficult subject of hospital management, and happened to ask him if there were any paying wards for private patients in any of the great *Krankenbad* hospitals. You never saw a man become so furious as Krauts when I put the question. "No, a thousand times no!" he shrieked. "But why not?" I exclaimed. "Hospitals are for the poor!" he shouted. "Yes," said I, "but the rich need charity sometimes. In a large city like *Krankenbad* there are many wealthy people who have no homes, no friends; what are they to do when they are ill?" "Go to bed, and send for me," replied Krauts. "Nothing could be better," I answered; "but how about the nursing? It is not likely that the doctor's orders would be carried out by mercenary and careless attendants." "That is true," said Krauts; "I found a bottle of brandy under the pillow of a noble lord who is suffering from delirium tremens, and also another bottle in his riding-boots. But for all that I will admit no noble lords into a public hospital. Better that the nobility should perish than that the medical profession should be disgraced!" "Who dares to speak of disgrace," I exclaimed hotly, "in the presence of an M. R. C. S., London, and L. S. A. of *Blackfrars*?" "Silentium!" roared Krauts. "I know your English love of gold! *Ich sch' wahrhaftig schon die Zeit*. I mean I know the time of the clock." "What time?" I asked. "The time," said Krauts, "when competition will ruin the great hospitals of London. I shall live to see your omnibuses and your railway stations stuck all over with glaring advertisements. Yes, thus it shall be: 'Here you are! Try St. George's Hospital! Bones skillfully set, and a first-rate diet for seven shillings sixpence a day!' 'Now is your time! Great reduction at St. Bartholomew's! Entirely new set of pulleys for dislocations, four meals a day, and smoking permitted. Charge six shillings eightpence, and no extras!' And there is worse than this," continued Krauts. "Doctor will be pitted against doctor. We shall read: 'Dr. Jones for hernia, always ready at the Middlesex; come quickly!' 'Dr. Smith for tumors at St. Thomas's! Size no object! Omnibuses pass the door every ten minutes!' And women, too, will be made to play their parts upon the stage of the operating theatre. We shall see placards: 'Where's Maria? Head nurse at Guy's, of course!' 'Who is Jemima? Why, the champion poulticee at Bartholomew's!'" "How dare you insinuate the possibility of such a state of things in England!" I exclaimed. "Because," said Krauts, "since I was in London I have carefully read your journals. Is this your English *Standard*?" he continued, as he handed me the following:—

"THE SILVER LINING.

"TO THE EDITOR OF THE STANDARD.

SIR.—In these days of hospital mismanagement, it may be refreshing to chronicle my recent experiences as an invalid in the 'Home' ward of the St. Thomas's Hospital, Westminster.

Having succumbed to severe accidental illness, which baffled my regular medical attendants, I followed a friend's advice, and took up my quarters in this establishment, where, for the small charge of eight shillings per day, I have had medical attendance, skilled nursing, eating and drinking, all of the very best.

"I cannot avoid writing this letter, if only as a sin-

cere thanks-offering to Dr. Edmonds and the management generally. I can only again repeat my gratitude to the attendants, especially to the particular nurse under whose care I was placed. Throughout, everything has been done that could tend to alleviate my sufferings, and I can only strongly urge any one, whether male or female (there are female wards), to at once follow my example should illness occur.

"I may add that a male dresser (formerly a member of the Army Hospital Corps) is always in attendance, and that a sitting-room, with books, etc., is provided. Smoking on the pleasant gallery overlooking the Thames is permitted.

"I am, sir, your obedient servant,

"A LATE PATIENT.

"LONDON, November 17th."

"Krauts, 'I said,' this is only the letter of a patient still weak from an operation—probably trephining." "That is so," replied Krauts; "I can make allowances for patients, but why did the Editor of the *Standard* put it in?"

I could not answer him, so I have written to you, sir, for an explanation.

I am, etc.,

ROBERT SAWYER.

PINK EYE IN HORSES.

MR. EDITOR.—This disease in horses is one of the varieties of catarrhal or influenza colds, so-called, prevalent in this climate among human beings, and springs from the same cause, namely, excessive, over frequent, or otherwise injudicious eating. The custom of working or exercising horses directly after eating; of feeding them directly after hard work, and before they are thoroughly rested; baiting at noon, when both these violations of a natural law are committed, these are the predisposing causes of pink eye, and of most diseases that afflict our horses. The symptoms denominated pink eye are not indicative of dangerous disease, unless feeding is kept up; but if it is, then pneumonia, which is merely an aggravation of the original disease, is very likely to result. Keep the horse quiet, dry, warm, and in a pure atmosphere. The nearer outdoor air the better, and *stop his feed entirely* at the first symptom of disease, and he will speedily recover. As prevention is better than cure, horsemen will do well to heed the hint here given and keep their creatures from contracting this or any other ailment. It has been demonstrated in tens of thousands of cases, in family life, that *two meals* are not only ample for the hardest and most exhausting labors, physical or mental, but altogether best. The same thing has been fully proved in hundreds of instances with horses, and has never in a single instance failed, after a fair trial, to work the best results.

An hour's rest at noon is vastly more restoring to a tired animal, whether horse or man, than a meal of any sort, although the latter may prove more *stimulating*. The morning meal given if possible early enough for partial stomach digestion before the muscular and nervous symptoms are called into active play; the night meal offered long enough after work to ensure a rested condition of the body; a diet liberal enough but *never excessive*, this is the law and gospel of hygienic diet for either man or beast. If it be objected that these conditions cannot always be fully met in this active work-a-day world; I reply: let us meet them as nearly as possible. We can, of course, do no more than this; but we can come nearer the mark on the two-meal sys-

tem than on three. I will add, *in parenthesis*, that the nervous disorder commonly known as "pulling" will yield readily to this principle of treatment. It makes the puller healthy; he is better nourished and therefore less "nervous;" and he will do more rouding, and without excitement, or profuse sweating. He is not made less ambitious by reason of reduced muscular power, but by reason of better digestion and assimilation,—more *nourishment* and less *stimulation*. Horse dealers, or others, whose business or pleasure depends on the plump appearance of their animals, regardless of the size of their muscles, who must have a horse fat if he is not fleshy, for style, may have to take the chances and feed three times a day, but of this I am by no means sure. I have never tried to fatten my horses,

for I long ago learned that fat is disease; but I have always found that if a horse does solid work enough he will be fairly plump if he has two sufficient meals. Muscle is the product of work and food; fat may be laid on by food alone. But for perfect health, and immunity from disease, restriction of exercise must be met by restriction in diet. Horses require more food in cold than in warm weather, if performing the same labor. In case of a warm spell in winter I reduce their feed, more or less, according to circumstances, as surely as I do the amount of fuel consumed. I also adopt the same principle in my own diet. The result is, that neither my animals nor myself are ever for one moment sick. Very truly yours,

C. E. PAGE, M. D.

BIDDEFORD, ME., December, 1881.

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 17, 1881.

Deaths reported 2701 (no reports from St. Louis and New Orleans): 986 under five years of age: principal "zymotic" diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas, and fevers) 617, consumption 395, lung diseases 316, diphtheria and croup 240, small-pox 92, scarlet fever 102, typhoid fever 68, diarrhoeal diseases 32, whooping-cough 25, malarial fevers 23, measles 18, cerebro-spinal meningitis 11, erysipelas eight, puerperal fever five. From small-pox, Pittsburgh 30, Chicago 25, Philadelphia 16, New York 12, Holyoke five, Cincinnati two, Baltimore, and New Bedford one each. From measles, New York 12, Pittsburgh and Buffalo two each, Chicago and Milwaukee one each. From scarlet fever, New York 58, Brooklyn 13, Buffalo 11, Philadelphia five, Pittsburgh four, Baltimore three, Milwaukee two, Springfield two, Cincinnati, Charleston, Worcester, and Salem one each. From cerebro-spinal meningitis, New York two, Worcester two, Philadelphia, Boston, Baltimore, Pittsburgh, Milwaukee, Lawrence, and Haverhill one each. From diphtheria and croup, New York 74, Brooklyn 32, Baltimore 30, Chicago 23, Philadelphia 15, Cincinnati 10, Boston nine, Buffalo six, Pittsburgh six, Lowell six, Milwaukee four, District of Columbia three, Worcester three, Taunton, Brockton, Attleborough, and Quincy two each, Providence, New Haven, Charleston, Nashville, Fall River, Lynn, Salem, Somerville, Newburyport, Waltham, and Spencer one each. From whooping-cough, New York 12, Philadelphia, Brooklyn, Chicago, and Boston two each, District of Columbia, Fall River, Taunton, Attleborough, and Holliston one each. From erysipelas, New York two, Chicago two, Brooklyn, Charleston, Nashville, and Westfield one each. From typhoid fever, Chicago 17, New York 12, Philadelphia 12, Milwaukee five, District of Columbia four, Pittsburgh four, Brooklyn and Boston three each, Providence, Lowell, and Cambridge

two each, Baltimore and Holyoke one each. From *malaria fevers*, New York 12, Brooklyn seven, Chicago two, Milwaukee and Charleston one each. From *puerperal fever*, New York, Brooklyn, Chicago, Baltimore, and Milwaukee one each. One hundred and four cases of small-pox were reported in Pittsburgh, 38 in Cincinnati, nine in Brooklyn, seven in Buffalo, four in Baltimore, one in District of Columbia, one in Lawrence.

Diphtheria 31, scarlet fever four, in Boston; diphtheria 12, scarlet fever five, in Milwaukee.

In 41 cities and towns of Massachusetts, with a population of 1,070,200 (population of the State 1,783,086), the total death-rate for the week was 20.69, against 21.61 and 19.80 for the previous two weeks.

For the week ending November 26th in 149 German cities and towns, with an estimated population of 7,798,351, the death-rate was 23.1. Deaths reported 3463; under five 1555; pulmonary consumption 475; acute diseases of the respiratory organs 286, diphtheria and croup 200, scarlet fever 120, diarrhoeal diseases 113, whooping-cough 50, typhoid fever 47, measles and röteln 43, puerperal fever 20, small-pox (Königsberg, Dresden, Aachen two) four, typhus fever (Königsberg, Stettin, Thorn, Tilsit) four. The death-rates ranged from 9.4 in Karlsruhe to 36.7 in Augsburg; Königsberg 28; Breslau 24.6; Munich 26.2; Dresden 21.5; Berlin 23.6; Leipzig 25.4; Hamburg 21.6; Hannover 19; Bremen 15.1; Cologne 23.4; Frankfurt 16.7; Strasburg 23.1.

For the week ending November 19th in the 20 English cities, with an estimated population of 7,608,775, the death-rate was 20.6. Deaths reported 3000; acute diseases of the respiratory organs (London) 345, scarlet fever 142, measles 97, whooping-cough 83, fever 74, diarrhoea 55, diphtheria 26, small-pox (London 13) 15. The death-rates ranged from 17.2 in Norwich to 27.6 in Hull; Leeds 17.8; Bristol 17.9; Sheffield 18.6; Birmingham

ham 19.1; London 19.5; Manchester 23.4; Liverpool 26.7. In Edinburgh 21; Glasgow 22.9; Dublin 21.2.

For the week ending November 26th deaths reported 3161; acute diseases of the respiratory organs (London) 382, scarlet fever 150, measles 118, whooping-cough 80, fever 75, diphtheria 36, diarrhoea 34, small-pox (London 20) 22. The death-rates ranged from 13.1 in Wolverhampton to 30.6 in Hull; Leeds 15.8; Sheffield 18.6; Bristol 19.1; Birmingham 21.4; London 21.8; Manchester 22.5; Liverpool 28.2. In Edinburgh 21.4; Glasgow 20.8; Dublin 29.1.

For the week ending December 3d deaths reported 3005; acute diseases of the respiratory organs (London) 336, scarlet fever 126, measles 106, whooping-cough 91, fever 60, diphtheria 33, small-pox (London 28) 31, diarrhoea 28. The death-rates ranged from 15.1 in Wolverhampton to 29.6 in Manchester; Birmingham 17.5; Bristol 18.6; Sheffield 19.4; London 19.9; Leeds 21.7; Liverpool 24.7. In Edinburgh 15.7; Glasgow 19.9; Dublin 24.5.

For the week ending November 12th in the 21 chief towns of Switzerland, population 479,934, there were 32 deaths from pulmonary consumption, acute diseases of respiratory organs 25, diarrhoeal diseases 13, diphtheria and croup 12, puerperal fever two, typhoid fever and small-pox one each. The death-rates were, Geneva 17.5; Zurich 16.2; Basle 16.7; Berne 25.8.

For the week ending November 26th there were 27 deaths each from pulmonary consumption and acute diseases of the respiratory organs, diphtheria and croup 16, diarrhoeal diseases 15, whooping-cough six, typhoid fever, small pox, and puerperal fever one each. The death-rates were Geneva 25; Zurich 24.4; Basle 19.3; Berne 30.4.

The meteorological record for the week ending December 17th in Boston, was as follows:—
